JEWS. After the Babylonish captivity, the Hebrews (see *Hebrews*) were called *Jews*, the greater part of the nation having remained in the middle and eastern provinces of the Persian empire, and only 42,360 men, with their families, principally of the tribes of the kingdom of Judah, having returned to their country, when permission was granted by Cyrus (536 B. C.). They founded a new kingdom in Judea, dependent on Persia, but under the domestic direction of high priests and elders, according to the Mosaic constitution. Jerusalem, the temple, and the Levitical cities of the country were rebuilt, not without difficulty; the writings of Moses, the historical and prophetic books collected; the great synagogue of 120 learned men established for the critical revision and explanation of the Holy Scriptures, as well as separate synagogues and schools for the expounding of the law, and the instruction of the people. All these institutions did not enable Ezra and Nehemiah, the restorers of their nation, to revive the primitive Mosaic constitution. The spirit of his code belonged to another age, and to other circumstances. The later Jews could retain only the letter of the law, and, in their expositions, lost themselves in the subtleties which they had learned from the Chaldeans. In enterprise and activity, however, they surpassed their fathers. Their commerce, and their annual pilgrimages to the temple, to which each Jew was obliged to make an offering, accumulated at Jerusalem, under the mild government of the Persians, more treasures than Solomon's age had ever seen. They were not therefore destitute of the means for conciliating the Macedonian conquerors, and although, on the fall of the Persian monarchy, they submitted to Alexander the Great, and were involved in the wars of his generals for the supremacy, yet their fate was not hard. Ptolemy, king of Egypt, who took possession of Palestine 320 B. C., allowed them the enjoyment of their singular customs, and granted the colonies which he transplanted to his capital (Alexandria), for the purpose of extending its commerce, peculiar privileges over the natives. The Jews were far from improving their condition by engaging in the war between the Syrian and Egyptian kings, on the side of the former (197 B. C.); for the Syrian Seleucids considered their possessions as lawful subjects of plunder. Seleucus IV. attempted to plunder their temple, and Antiochus IV., in order to reduce them to a uniformity with the rest of his subjects, determined to destroy their religion. His pretext for this was the shameful spectacle of intrigue and corruption displayed at the Syrian court, in the rivalry of the priests and nobles for the dignity of high priest; but the nation adhered, with its characteristic obstinacy, to the forms of the Mosaic worship. When, therefore, Antiochus set up the Olympian Jupiter for worship in the temple, and compelled the Jews to sacrifice and eat swine, many suffered the most terrible death, rather than transgress the law of Moses. In vain were Jerusalem and the surrounding country laid desolate. These persecutions only served to develop a national spirit, which broke out in the insurrection of the Maccabees. Judas, surnamed *Maccabeus* (the hammer), was the third son of a priest, who had fled, with his family from persecution, and had collected, in the mountains of Judea, a band of faithful believers.

With their assistance, he defeated the Syrians, took Jerusalem, and restored the Mosaic worship (165 B. C.) A new epoch of glory and renown for the Jews began under the government of the Maccabees, three brothers of this family of heroes—Judas, Jonathan, and Simon—bore successively the dignity of high-priest, and completed their deliverance from the Syrian yoke. Simon, whom the gratitude of the nation had created a prince, left to his son, John Hyrcanus (135 B. C.), an independent kingdom, secured by an alliance with the Romans. The latter extended it by his victories over the Idumeans and Samaritans, and confirmed it by the establishment of the high council, or sanhedrim. The reign of Hyrcanus was distinguished for the progress of civilization and the increasing prosperity of the nation. In his time also arose the sects of Pharisees, Sadducees, and Essenes, (q. v.) His son Judas Aristobulus, received the royal dignity (105 B. C.), and the Jewish state appeared to be in the way to recover the power and splendour of David's time, since Alexander Jannæus, the successor of Aristobulus, took Gaza, in a successful war against Egypt; but the above-mentioned sects gave rise to civil dissensions. After the death of queen Salome (70 B. C.), who was ruled by the Pharisees, the succession was disputed by her sons Hyrcanus and Aristobulus. The war between the brothers introduced foreign umpires into the country. Pompey conquered Judea (63 B. C.), according to the Roman policy, for the weak Hyrcanus. This result of the contest put an end to the new freedom of the Jews. Jerusalem lost its walls, the kingdom its new conquests, the nation its independence, and the family of the Asmoneans (the *illustrious*, a title borne by the Maccabees), its royal dignity. Hyrcanus was made high-priest and ethnarch, and each Jew became a tributary to the Romans. It was in vain that the sons of Aristobulus endeavoured by repeated insurrections, to restore the former state of things. The Roman power kept the people in chains, and a false friend (Antipater of Idumea) introduced himself, as a Roman procurator, into the family of Hyrcanus, to effect its ruin. While the Asmoneans were struggling for independence, Herod, Antipater's son, was securing the kingdom for himself at Rome. Antigonus, son of Aristobulus II., who had maintained himself five years in Jerusalem, by the assistance of the Parthians, was expelled by the new king Herod (q. v.) 35 B. C., and the last of the Asmoneans was put to death. The reign of this foreign king, who acquired the name of the *Great* by maintaining himself amidst many difficulties, was of no advantage to the country. The doubtful character of his faith made the chief men, who were dependent on him, indifferent to their ancient religion, and the murders which he committed in his own family, as well as the unceasing oppression of the Romans, filled the people with general discontent. The divine worship constantly degenerated more and more into empty forms, and the licentiousness of the court contaminated all ranks of the nation. Such was the situation of the Jews and of Judaism when Christ was born. Herod survived this great event to stain his last days by the murder of the children of Bethlehem; but neither he and his successors, nor the councils of the Pharisees, could avert the fate of the Jews. Under the feeble princes who succeeded Herod, the country soon came to be treated merely as a Roman province. Oppressed by the procurators, precluded from the exercise of their religion, the infuriated people broke out into a rebellion (A. D. 66) which terminated in the total destruction of the Jewish state. September 7, A. D. 70, Titus took Jerusalem by assault, burned the temple, demolished the city, and sold into slavery, or drove into

exile, all the inhabitants who escaped death. About 110,000 Jews perished during the siege, and at the destruction of Jerusalem. There was no suffering which this unhappy people did not undergo. These Jews who had taken refuge in the mountains and the ruins, were compelled, after many unsuccessful efforts, to abandon their country, now changed into a barren desert.

The remnants of the nation, scattered over all the earth, still possessed advantages which could bring to no other people in similar unhappy circumstances. Their natural ingenuity and industry, the strength of their religious seal, the literary treasures of their holy writings, secured to them every where admittance and success, and preserved their national character. They found proselytes and old believers in all countries of the Roman empire, and in the East, as far as the Ganges, where those who had settled, during the Babylonish captivity, had greatly multiplied. Egypt, and the northern coast of Africa, were filled with Jewish colonies, and in the cities of Asia Minor, of Greece and Italy, were thousands enjoying the rights of citizens. Thus, by their mutual connexions, and by their holy books, they became the involuntary instruments of the propagation of Christianity, which but few of their own number embraced. They were not required to receive it by the Roman emperors. Under the emperor Julian, they ventured to make preparations for a new temple in Jerusalem, which had been rebuilt by Adrian, under the name of *Ælia Capitolina*. Although this attempt failed, they derived great advantages from their sanhedrim, revived at Tiberias, and their patriarchates (presidencies of the sanhedrim), which were established—one at Tiberias, for the Western Jews (429), the other for the Jews beyond the Euphrates, first at Mahalia, afterwards at Bagdad. The former was hereditary, the latter, elective by the sanhedrim at Bagdad. The incumbent of the latter, which subsisted till 1058, was called *aichmatotarca* (prince of the captivity.) These two patriarchates became points of union, and their flourishing academies in the East served as seminaries for their learned rabbins. One of the works of these scholars was the collection of the traditional expositions of the Old Testament, and additions to it, which was begun, A. D. 200, by rabbi Jehu the Holy (Hakkadosh), completed A. D. 500, and received, under the name of the *Talmud*, as a rule of faith, by the scattered communities of Jews. It requires that wherever twelve adults reside together in one place, they shall erect a synagogue; and, since the destruction of the temple had put an end to sacrifices, they are to serve the God of their fathers by a multitude of prayers, and little formalism, amidst the daily occupations of life. This book of law allows usury, treats agriculture and grazing with contempt, requires the strictest separation from other people, commits the government to the rabbins, as the teachers and nobles, and inculcates a corrupt moral system, which has degraded the character of the great mass of this unfortunate people, rendered them dangerous to those among whom they live, and obstructed their naturalization, even where they enjoy the greatest privileges. This applies to the Rabbinites (that is, the followers of the Talmud), to which sect nearly all the European Jews belong. The sect of the Caraites, who reject the Talmud, and hold to the law of Moses only, are less numerous, and are found chiefly in the East, in Turkey and Eastern Russia. During the decline of civilization in Europe, when the Jews had settled as colonists, even under the Romans, and had penetrated as far as Gaul and Germany, owing to the slave-trade, they preserved, a certain degree of civilization by means of their schools, which, during the confusion consequent on

the destruction of the old, and the formation of new states, by the irruption of the barbarians, not only preserved their existence, but obtained them influence and authority. They made themselves masters of the commerce of the old world, and, as money-lenders and brokers, were often of great importance to princes and nobles; and, during the dreadful persecutions which they underwent from the cruelty of the Christians, even after the seventh century, they still continued prosperous in those countries, even during the periods in which they suffered most. Their own usury, and the rapacity of the Christians, rather than religious hatred, were the true causes of these persecutions. The most dreadful crimes, and all public calamities, were attributed to them by the Christians, as a pretext for ridding themselves of troublesome creditors, or for obtaining possession of their treasures, either by their execution or banishment; but their wealth and adroitness had rendered them so important, that they were always able, eventually, to secure the protection of spiritual and temporal rulers. They lived more happily among the Mohammedans, although they were distinguished by dishonourable badges, and oppressed by heavy taxes; and, during the Moorish supremacy in Spain, their prosperity was increasing, and their learning flourishing. See *Rabbinical Language and Literature*.

In the cities of France, Germany, and Italy, after the eleventh century, particular streets and enclosed places, were assigned to them, in consequence of which, in the persecutions during the crusades, thousands often fell victims at once to the popular fury. Decrees of councils, and the ordinances of secular rulers, repeatedly declared the Jews incapable of enjoying the civil rights of Christians, and of holding public offices. They could no where be domiciliated, nor attached to any guild or corporation; but, in consideration of the payment of certain sums of money, they enjoyed the immediate protection of the sovereign, who, in his financial embarrassments, obliged them to make repeated contributions. In Germany they paid a considerable tax, in return for which they were protected, as the money agents (*Kammerknechte*) of the holy Roman empire, as they are denominated in an imperial letter of protection. Their conversion to Christianity could not be effected by such treatment. In Spain and Portugal, indeed, at the end of the fifteenth century, they yielded to force, and suffered themselves to be baptised *en masse*; but, as soon as the storm was over, they were seen again in the synagogues. The superstition of the fifteenth century, whose worship of saints and relics must have appeared to them idolatry, might well persuade them that their own pure monotheism was more rational and scriptural. From this circumstance, and from their pride in the antiquity of their nation and constitution, we may infer how many of those who publicly professed to be converts to Christianity, and were called, in Portugal, *new Christians*, and who might attain to a noble rank, and even to high church dignities, were still, in private, Jews, continuing scrupulously to observe the Mosaic ceremonies.\* The Portuguese Jews, on account of their connexion with these secret adherents to Judaism, have been particularly respectable, and are in possession of large landed estates. The Dutch Jews, chiefly fugitives

from Portugal, were once distinguished for their immense wealth. The Polish (who, since 1264, have been in possession of important privileges, and have been a great hinderance to the industry of the cities) and the Russian (now the most numerous) have possessed themselves of nearly all the commerce; also of the inns, the beer and brandy shops, and, in some places, of the post-offices. The German Jews, on account of the increase of the commercial cities and corporations, have kept only the gleanings of the retail trade. In all places, the Jews have a peculiar character. Their confinement to employments which depend principally on ingenuity and cunning, has had a debasing effect on the great body of them. In modern times, however, distinguished scholars, philosophers, artists, physicians and merchants have been found among them; as Spinoza, Moses Mendelssohn, David Friedlander, Moses Kuh, &c.

The philosophical spirit of the last half of the eighteenth century first began to acknowledge the rights of the Jews. Plans for the improvement of their political and moral condition were discussed, and afterwards, by the benevolence of some governments, carried into execution, but with little, and often with no success. The only consequence of the great sanhedrim, to which the emperor Napoleon summoned 100 rich Jews (1806), was an imperial decree, soon after, declaring those Jews only to be French citizens who were occupied in some useful employment; but they were still drawn as conscripts. The German princes were more desirous to give the rights of citizenship to the Jews. The disabilities to which they had hitherto been subject, were removed; civil privileges were granted to them; the Israelitish consistory was established in Cassel, under the Westphalian government, for the improvement of their worship and their schools. Still more important are the improvements in the Jewish schools in Austria, where there are academies for rabbins at Prague and Lemberg; in Bavaria, where there is a similar institution, at Furth; and in the Prussian states, where they acquired all civil rights in 1811. There is no distinction whatever between Jews and Christians by the constitution of the United States, but, in some of the states, certain officers, as the governor, counsellors, representatives, are required to profess, under oath, their belief in the Christian religion. In England, the Jew bill, passed in 1753, enabling Jews to prefer bills of naturalization in parliament, without receiving the sacrament, was repealed the next year. In May, 1830, an attempt was made, in parliament, to remove the civil disabilities affecting the Jews, but was opposed by the ministry, and the question was lost. In France, the chamber of deputies voted, in 1830, that the Jewish ministers of worship should be paid from the public chest, like the Christian. In Germany, a number of Jews have lately abandoned the system of the rabbins, and performed divine worship in the German language, in a manner approaching that of the Christians. Hamburg is the seat of this society. In general, the Jews in Europe, without renouncing their religion, have, more than formerly, shown a disposition to adopt Christian refinement, while their brethren among the Mohammedans and heathens share the barbarism of their masters. By the ukase of March, 1817, important privileges are conferred on the Jews in Russia who embrace Christianity. Land is given to them gratuitously, where they may settle under the name of *The Society of Israelitish Christians*. They are immediately subject to a court at Petersburg, appointed by the emperor, are exempt from military service, from having soldiers quartered on them, from all taxes for twenty years, and may engage in any trade without being subject to the restrictions of the craft.

\* It is well known that the literature of Spain is much indebted to the Jews. A list of authors of Hebrew origin gives 361 on philology, twenty on astrology, sixty-seven commentators, or expositors, eighty-four on philosophy, fifty-two in grammar, thirty-six on medicine, eighteen historians, fifty-two jurists, eighteen mathematicians, fifty-seven poets, eight on rhetoric, sixty-eight on the Talmud, nineteen theologians, and seventy-three translators.—*Journal of the Literary Convention*, held at New York, Appendix, No. 1. (New York, 1831).

(For the institutions for the conversion of the Jews, originating in Britain, see *Missions*.)

The following is an estimate of the number of Jews in different parts of the world, taken from the Weimar *Ephemeriden Geographischen*:—*Europe*; in Russia and Poland, 658,809; Austria, 453,524; European Turkey, 321,000; States of the German Confederation, 138,000; Prussia, 134,000; Netherlands, 80,000; France, 60,000; Italy, 36,000; Great Britain, 12,000; Cracow, 7300; Ionian Isles, 7000; Denmark, 6000; Switzerland, 1970; Sweden, 450: total number of Jews in Europe, 1,918,053, or a proportion of 113th part of the population, calculated at 227,000,000.—*Asia*; Asiatic Turkey, 300,000; Arabia, 200,000; Hindostan, 100,000; China, 60,000; Turkestan, 40,000; province of Iran, 35,000; Russia in Asia, 3000; total, 738,000.—*Africa*; Morocco and Fez, 300,000; Tunis, 130,000; Algiers, 30,000; Abyssinia, 20,000; Tripoli, 12,000; Egypt, 12,000; total, 504,000.—*America*; North America, 5000; Netherlandish colonies, 500; Demerara and Essequibo, 200; total, 5700. New Holland, 50. Grand total, 3,218,000. Other estimates carry the number to five or even six millions. The black Jews, in the East Indies, are natives, and slaves who have embraced Judaism.

See Basnage, *Histoire des Juifs*, from the Christian era to 1716 (fifteen volumes); J. M. Jost's *History of the Israelites since the time of the Maccabees*, (Berlin, 1820—1826, seven volumes, from 105 B. C. to A. D. 1820.) On the civil condition, commerce, and literature of the Jews in France, Spain, and Italy, during the middle ages, from the beginning of the eighth to the end of the sixteenth century, see Arthur Beugnot, *Les Juifs de l'Occident*, &c. (Paris, 1824). The best religious history of the Jews is Peter Beer's *History, Doctrines, and Opinions of all the religious Sects that have existed or do exist among the Jews, and of the mystical Doctrine of the Cabbala* (Brunn, 1822, two parts). See Zeo's *History of the Jewish States* (Berlin, 1828); see also the *Hebrew Commonwealth*, translated from Jahn's *Biblische Archæologie* (Andover, 1828), and Milman's *History of the Jews* (London, 1829).

*Jewish Law.* The sources of the Jewish law are the Mosaic law and the Talmud; hence the rabbis are the Jewish lawyers. The Jewish law in all its extent, is very complicated, and full of niceties. In some countries of Europe, the Jews enjoy a separate jurisdiction to a certain degree, and inherit according to their own law. (a) The Jewish matrimonial contract is made partly in writing and before witnesses, and partly by the delivery of a ring to the bride from the bridegroom. The husband acquires a right to every thing which his wife obtains by labour or otherwise; he has also the use of the fortune which she possessed at the time of the marriage, and is her sole heir. Testaments are governed by the principles of the *donatio inter vivos* and the *donatio mortis causa*, according as the will was made, in a state of health, or of dangerous sickness. The rules of legal descent among the Jews are as follows:—(aa) Among the descendants, the sons and their male descendants inherit first; after them the daughters, and, in case of there being none, the female descendants in the next degree. (bb) After the descendants follows the father; if he is dead, the brothers of the deceased and their descendants, and, in failure of all these classes, the sisters of the deceased and their descendants. Persons related by the mother's side never inherit from each other: children may inherit from the mother; the mother never can from the children. Legitimate children do not exclude illegitimate, even if the fruit of an incestuous connexion, unless the mother of the illegitimate children is a slave, or not of Jewish

blood; in which case, the children do not inherit from the father in any event. The first-born son receives a double share of the property which the father actually possessed, not, however, of uncollected debts. On the other hand, he has to bear also a double share of the debts due from his father. If the first-born dies before the division takes place, his right of primogeniture falls to his descendants. Any one may renounce, sell, or give away his right of primogeniture. The hereditary succession of the husband and wife is regulated by the time of the continuance of the marriage. (c) Every grant must be public, and the property be regularly transferred; to annul a legal grant, a new grant, with proper formalities, is requisite. A verbal grant is binding only when made by a very sick person, or one in imminent danger. A Jew attains his majority at the age of thirteen years and one day, if he has obviously reached the period of puberty. A Jewess, under the same circumstances, is of age at twelve years. A Jew is not allowed to engage in commerce before his twentieth year. The girl remains, until she is full grown, under the paternal authority, when the father may give her in marriage, against her knowledge and wish. According to the laws of several countries, full age of Jews is the same as that of other inhabitants.

JEWS-HARP is a kind of musical instrument held between the teeth, which gives a sound by the motion of a spring of iron, which, being struck by the hand, plays against the breath. "The Jews-trump," says a diligent investigator of such matters, "seems to take its name from the nation of the Jews, and is vulgarly believed to be one of their instruments of music. But, upon inquiry, you will not find any such instrument as this described by the authors that treat of Jewish music. In short, this instrument is a mere boy's plaything, and incapable, of itself, of being joined either with a voice or any other instrument. and I conceive the present orthography to be a corruption of the French *jeu trompe*, a trumpet to play with. And in the Belgic or Low Dutch, from whence come many of our toys, a trumpet is a rattle for children. Sometimes they will call it a *Jews harp*; and another etymon given of it is a *jaws-harp*, because the place where it is played upon is between the jaws." *Peage Anonymiana*, i. 82.

JEZIRAH, in the Cabbala, is the third world, the world of the thinking substances. In the Cabalistic theology, it is also the name of a book, in six chapters, which treats of the world, of motion, of time and of the soul. It is extremely obscure; everything in it is expressed in numbers and letters. One tradition makes the patriarch Abraham the author. It is mentioned in the Mishna and Sanhedrin, and, therefore, must have existed before the Talmud. The book is very short, and many editions have been published. The last edition is by Rittangel (Amst. 1648, with a Latin translation, equally incomprehensible.

JIDDA or JUDDA; a considerable commercial haven of Arabia, on the shore of the Red sea. It may be considered as the port of Mecca, and is supported partly by carrying on the trade with India and Egypt, and partly by the concourse of pilgrims from the coast, and of those from the opposite regions of Africa, who cross at Suakem to reach this famed seat of Mohammedan pilgrimage. It is situated in a barren, sandy district, destitute of water. The streets are very narrow. The entrance to the road is full of shoals, and it is dangerous to attempt going in without a pilot. The British trade here was formerly considerable; but numerous exactions have now reduced it to a low ebb. The Americans have some commerce with this place. Lon. 39° 15' E., lat. 21° 29' N. For further information, see Burckhardt's *Travels in Arabia*.

JIHON, or GIHON, or SIHON, or AMOL, or AMU (anciently *Orus*); a river of Central Asia, which rises from mountains between Great Bucharía and Chinese Tartary, and, after a N. W. course of more than 1200 miles, flows into the lake of Aral. The cities of Samarcand, Bucharía, Termed, Balk and Gaur are on its branches. It has been generally believed, that it formerly flowed into the Caspian sea, and that its course was turned into its present channel by the Tartars, according to some, before the sixteenth century, but according to others, about 1719. This opinion is rejected by Malte-Brun, and other geographers, who maintain that the Jihon always flowed into the lake of Aral, and that the rejected opinion was formed and propagated by persons whose knowledge was imperfect, particularly with regard to the form of the Caspian sea, or the existence of the lake of Aral.

JOAB, son of David's sister, and his first general, fought valiantly for David, but often showed a revengeful and artful spirit; for instance, against Abner (2 *Samuel*, iii. 27, 39) and Amasa (2 *Samuel*, ix. 9, seq.) His services secured him the favour of David, though that king was often offended with him (2 *Samuel*, xviii. 33, xix. 4.) After David's death, he espoused the cause of Adonijah, and was killed in the temple, by the altar, at the command of Solomon (1 *Kings*, ii. 28, seq.)

JOACHIM MURAT. See *Murat*.

JOACHIMSTHALER. See *Dollar*.

JOAN, the papess, according to a story long believed, but now acknowledged to be a fiction, was a native of Ments, of the name of Gilberta or Agnes, who, falling in love with an Englishman at Fulda, went to travel with him, studied at Athens, and visited Rome. Continuing to conceal her sex, she took the name *Johannes Angelicus*, and rose, by her talents, from the station of a notary to the papal chair, under the name of John VIII (854 to 856, between Leo IV. and Benedict III). She governed well, but, having become pregnant by a servant, or, according to some, by a cardinal, she was delivered in a solemn procession, and died on the spot, near the Coliseum, which place the popes are said to have avoided ever after in their processions. This story, first related by Marianus Scotus, in his *Chronicon* (in the twelfth century), is not mentioned by any contemporary writer hostile to the papal see, and is generally considered, since Blondell's *Eclaircissement sur une Femme*, as a mere fable. The examination on the *sella stercoraria*\* perhaps gave rise to this story; perhaps it is a satire on the barefaced profligacy of some popes; perhaps it is a fruit of the excitement against the popes, which became very general in the thirteenth century; others still have thought it to be an allegory of the decretals of the pseudo Isidore, then brought to light. Clemens Sylvius first showed the falsehood of the story. Spanheim defended the account in his *De Johanna Papissa*. Gibbon says, "Till the reformation, the tale was repeated and believed without offence, and Joan's female statue long occupied her place among the popes, in the cathedral of Sienna. She has been annihilated by two learned Protestants, Blondell and Hayle; but their brethren were scandalized by this equitable and generous criticism. Spanheim and L'Enfant attempted to save this poor engine of controversy; and even Mosheim condescends to cherish some doubt and suspicion."

\* From the time of Honorius II. 1064 to Leo X. the popes were actually obliged, after their election, to seat themselves upon a stool with an opening, where they were examined by the youngest deacon, in order to determine that they were males, with their organs perfect, because no mutilated person can be a member of the Catholic priesthood.

JOAN OF ARC (*Jeanne d'Arc*); the Maid of Orleans. The belief, prevalent in the middle ages, that particular individuals were gifted with supernatural powers, as instruments of a higher will, explains the extraordinary character and conduct of the maid of Orleans. After the death of Charles VI. king of France, in 1422, Henry VI. of England, then a child of nine months old, was proclaimed king of France, according to the treaty of Troyes (1420); his uncle, the duke of Bedford, acted as regent. France had been distracted, for forty-two years, by civil dissensions. On one side were queen Isabella, the duke of Burgundy, and England; on the other, the dauphin Charles, who had been abandoned by his own mother, was supported by the Orleans party. This division, and the talents of the English generals, the earls of Somerset, Warwick, Salisbury, Suffolk, Arundel, Talbot, and Fastolfe, had reduced nearly all France to the dominion of England. The dauphin, a youth of nineteen, was crowned at Poitiers as king Charles VII. He possessed many qualities proper for interesting his countrymen in his favour, and was wanting only in firmness and resolution. Still he maintained himself in France for the space of seven years. At length, Bourges, and the territory belonging to it, were nearly all that remained to him. Paris and the north of France, as far as the Loire, were in possession of the English. Salisbury had been besieging Orleans since October 12, 1428. The city was bravely defended by Gaucour. Its fall would have ruined the cause of Charles. In the valleys of the Vosges, on the old frontiers of Lorraine, in the village of Domremy la Pucelle, on the banks of the Meuse, lived a peasant girl, Jeanne d'Arc, whose parents were common country people of reputable character, and in good circumstances for their station. In the midst of timid and superstitious persons, who were in continual trouble and alarm at the misfortunes of their country, Joan was quietly occupied in domestic employments, and sometimes in driving the cattle to pasture. Her history has been very minutely traced. The third volume of the Notices and Extracts from Manuscripts in the library of the king, by De l'Averdy (Paris, 1790, 4to), contains whatever is important respecting her, taken from twenty-eight manuscripts relating to her trial and condemnation. She was of a delicate frame, and uncommon sensibility of temperament. This, perhaps, was heightened by the circumstance of her being exempt from the common law of her sex; and Dufresnoy has remarked how this circumstance and her spirit of devotion may account for her visions. Her enthusiasm, and her habits of solitary meditation, explain the angelic voices and visions of the maid. While her companions were sporting beneath the *Fairies' tree*, the beautiful May (*le beau Mai ou l'arbre des fées*), not far from the fountain of Domremy—a tree which was once sacred to the Druids, and famous in many a ghostly tale—Joan was singing and dancing by herself, in pious enthusiasm, and binding garlands for the holy virgin, in the little chapel of "our Lady of Bellemont," which she usually visited on Saturday. She was never a servant, at least not in an inn. The English chroniclers have misrepresented these facts; and Hume is also in error with regard to her age. The beautiful Joan was but eighteen when she went to the dauphin at Chinon in Touraine. Commanded, as she asserted, by a vision of our lady of Bellemont, to raise the siege of Orleans, and to conduct Charles to Rheims to be crowned, she presented herself in February, 1429, to the governor of Vaucouleur, Robert of Baudricourt, who at first thought her possessed, and twice dismissed her; but upon her returning a third time, he sent her to Chinon with

letters of recommendation. Here the dauphin ordered her to be examined by the bishop of Meaux and John Morin. She is also said to have immediately pointed out the king, whom she had never seen, and who had purposely mixed among his courtiers, and to have repeated to him a prayer which he had made to the virgin Mary. It is certain that she was examined for three weeks, by many intelligent men, counsellors of parliament and divines. She was then secretly inspected by the dauphin's mother-in-law and her court ladies, who declared her to be a true virgin (*qu'elle était une entière et vraie pucelle*). At length, being satisfied of the truth of her claims, D'Aulon the most virtuous man at court, was appointed to be her constant attendant and brother in arms, and she received permission to hasten with Dunois to the deliverance of Orleans. From this period, she appears the finest character in the history of the middle ages of France. In a male dress, armed *cap à pie*, she bore the sword and the sacred banner, as the signal of victory at the head of the army. Still no unfeminine cruelty ever stained her conduct. She was wounded several times herself, but never killed any one, or shed any blood with her own hand. There appears, as Fr. Schlegel says in his History of the Maid of Orleans, from old French Documents (*Geschichte der Jungfrau von Orleans, aus altfranz. Quellen*, Berlin, 1820), there appears to have been no other earthly passion in her heart than devotion to her country, to the descendant of St Louis, and the sacred lilies. It is shown also, by the documents of her trial, and of the revision of it, in 1453, that she had not killed any of the enemy with her own hand, from a tenderness of conscience, and was even more anxious about the souls than the bodies of the English who were slain. Nevertheless, it would seem from some passages of Lenglet Dufresnoy (*Histoire de Jeanne d'Arc, Vierge Héroïne*, Paris, 1753, and Amsterdam, 1759), that she did not always carry the banner, and actually made use of the consecrated sword in case of necessity. This sword was taken by her directions from the church of St Catharine at Fierbois, where, according to the story, nobody had before known of its existence. After sunset, she avoided the company of men, passed her nights with women, and kept all loose females, as much as possible, away from the camp. The general belief of her elevated mission, of which she herself was piously persuaded, produced the most extraordinary effects. Resolute, chivalrous, pious and brave, looking to one single aim, she was skilfully employed by the generals to animate the army, while they did not implicitly follow her counsels. The first enterprise was successful. With 10,000 men, under the command of St Severre, Dunois and La Hire, she marched from Blois, and, on the 29th April, 1429, entered Orleans with supplies. By bold sallies, to which she animated the besieged, the English were forced from their intrenchments, and Suffolk abandoned the siege (May 8, 1429). Joan next captured several places in the enemy's possession, and defeated them in a battle near Patay, where general Talbot was taken, and the valiant Fastolfe himself was forced to fly. Charles entered Rheims in triumph. At the anointing and coronation of the king, July 17, Joan stood at his side. In full armour, and bearing the banner, she took the office of a constable, and held the sword over the king. Her commission having been thus fulfilled, she wished to return to her home, but was prevailed upon to stay. All France now acknowledged Charles as king; and Bedford could only maintain himself by valour and prudence. He repulsed, in September, the assault upon Paris. Here Joan was wounded, and Charles retired to Bourges. A title of nobility was now conferred on

the heroine and her family. She was first called *Dalis*, then *Duliz*, and, finally, *Dy Lge*; her coat of arms contained two golden lilies and a sword pointing upwards and bearing a crown. Meanwhile Bedford was assembling new forces. Burgundy and Brittany still acknowledged the young king Henry VI., who had been crowned at Paris. Thus strengthened, the English again pushed on and besieged Compiègne. The maid threw herself into the town, as she had done at Orleans, but in a sally, May 23, 1413, was taken prisoner by the Burgundians. She surrendered to Lyonnel, the bastard of Vendôme. She was at first confined at Crotot, but afterwards at Beaufort. Upon hearing that she was to be delivered to the English (king Henry having paid 10,000 livres for her), she attempted to escape by leaping from a window of the castle, and was seriously injured. In this condition, she came into the power of the English. At the instigation of her own countrymen, Pierre Cauchon, bishop of Beauvais, mounted a process against her, and the university of Paris demanded her execution. She was condemned by the church as a sorceress and heretic. The secular arm had no control over this decree. De l'Averdy gives this as an excuse for the inactivity of the king, who made little exertions in behalf of the heroine. But that light and indolent prince never showed himself zealous and constant in any thing. After four months' imprisonment, the innocent enthusiast, who had resolutely defended herself, and at the examination had named St Michael as the angel whose voice she had heard in her father's garden, in her fifteenth year, and as her constant guardian and attendant, was sentenced, by the inquisitors at Rouen, to be burnt for sorcery and intercourse with infernal spirits. She was carried, May 24, 1431, to the stake, when her courage appeared to be daunted. She submitted to the church, and declared her revelations to be the work of Satan. Her punishment was then commuted to perpetual imprisonment. But pretexts were soon found to treat her as a relapsed criminal, and, as such, she was burnt by a slow fire at Rouen, May 30, and her ashes were thrown into the Seine. She died with undaunted fortitude. When they were putting the inquisition cap on her head, before going to the pile, she said to her attendant, *Maître, par la grace de Dieu, je serai ce soir en paradis*. There is a tradition that, when she expired, a white dove was seen to rise from the pile. Among the divines who had condemned her, there was only one Englishman, the bishop of Winchester. In 1450 and 1451, measures were taken for reviving the process. 1455, the relations of Joan applied for a revision. Pope Calixtus III. committed the affair to the archbishop of Rheims, the bishops of Paris and Coutance, and an inquisitor. This court pronounced, in 1456, their decision, that the twelve articles alleged against her were false, and declared her entirely innocent. Her memory was preserved by monuments. In the market-place at Rouen, there is a statue of her, on which, under her coat of arms is the inscription:

*Regia virginio defraudat eas corona.  
Lilia virginio tula sub eam nitent.*

The maiden's sword protects the royal crown.  
Beneath the maiden's sword the lilies safely bloom.

According to the portrait of the maid, which Alvin Lenoir discovered in the town-house at Orleans, where there is also a statue of her, and which he sent to the Paris museum of French monuments, *Les petites Augustines*, she must have been exceedingly beautiful. Her features have a soft and endearing expression; they have what the French call *l'air du calme*. She has a cap with feathers on her head, and is holding in her hands a shield and the cross-staff.

sword. A monument, with her bust, in marble, was erected to her in Domremy, September, 1820.

See Berriat St Prix, *Jeanne d'Arc, ou Coup d'Épée sur les Révolutions au Temps de Charles VI. et VII.* (Paris, 1817); Lebrun des Charmettes, *Hist. de Jeanne d'Arc* (from original documents, Paris, 1817, three vols.); Jollois, *Hist. abrégée de la Vie et Exploits de Jeanne d'Arc* (Paris, 1821).—The name of the maid of Orleans is no less celebrated in the annals of poetry. The epic and romantic character of this subject has been variously managed by different authors. Chapelain, a contemporary of cardinal Richelieu, in his epic poem, *La Pucelle*, sang her exploits in twelve times 1200 wretched verses, as Boileau says. In 1730, Voltaire undertook to parody the monstrous production of his predecessor, and, following Shakespeare, who had introduced this subject as an episode in the First Part of his *Henry VI.*, where he represented the maid as a witch in confederacy with evil spirits, he turned the whole stream of his impure wit upon the subject. Thus was produced that too well known mock heroic poem, which Mercier called "a crime against the nation" (*crime anti national*). It first appeared in print, 1757. The first poetical attempt towards restoring a subject, thus profaned by the grossest wit, to its native dignity, was made by Robert Southey, in his epic *Joan of Arc*. Du-ménil's *Epopée Jeanne d'Arc, ou la France sauvée* (Paris, 1818), is very poor; D'Avrigny's *Pucelle d'Orléans*, a tragedy, has been occasionally performed at Paris; Alex. Soumet's *Jeanne d'Arc, Tragédie en cinq Actes et Vers*, appeared in 1825. But all these fall infinitely below the noble tragedy of Schiller, *Die Jungfrau von Orléans*, which first appeared in 1802. He has done more than Calixtus III. for her fame; he has restored the high-souled enthusiasm to her rightful place in the age of romance to which she belongs. He shows us the chivalrous heroine as an instrument of Heaven, engages our love for her, and makes her fall in glorious strife with her country's foes. Wetzel's *Joan of Arc*, a tragedy (Leipsic, 1817), adheres more strictly than Schiller's to historical truth. Lebrun des Charmettes' *Orléanide*, a poem in twenty-eight cantos (Paris, 1820), is modelled after the drama of Schiller.

JOANNINA, or JANINA; the capital city of Turkish Albania (Epirus), on the lake of Acherusia, in which there is an island with a strong castle, where resides the pacha of Janina. (See *Ali*, and *Greece, Revolution of*.) The city has a Greek archbishop, and about 30,000 inhabitants, mostly Greeks, who carry on a considerable commerce with Austria, Russia, and the Ionian islands. Joannina was formerly the centre of the literary intercourse between the modern Greeks and Italy, France and Germany. At the end of the last century, there were in this city two celebrated schools, in which mathematics and philosophy, together with ancient Greek, were taught. The one was founded by a merchant, Ghioni, in the last half of the seventeenth century, the other about 1790. They had two libraries and a cabinet of natural history. The inhabitants of Joannina, who are among the best informed and most industrious of the Greeks, deposited the funds of the two colleges in the treasury of Venice; but, by the fall of that republic, they were lost. The schools were, however, maintained by the generosity of three Epirotes in Russia—the brothers Zosima and Pikrosoy; the schools also received the interest of a million of rubles deposited in Russia. At the bombardment of the city by Ali Pacha, 1820, the buildings belonging to these institutions were destroyed, and all the books and manuscripts which they contained, among which were the original manuscripts of the geographer Meletius, a native of Joannina, were burnt.

Besides the Greeks, there are in Joannina Mohammedans, Jews, and Gypsies, but they all speak Greek.

JOB (Hebrew *Hiob*, i. e. the sufferer, the persecuted); the hero of an ancient Hebrew poem, which has been preserved to us in the canon of the Old Testament. It has been much disputed whether Job is a real or fictitious personage; whether the poem is epic, didactic, or dramatic; who is the author; what was his age and country; and when and where the scene is laid. The work has been attributed to Job himself, Moses, Elihu, Solomon, and others. The scene of the poem (the land of Us) is supposed to be in Arabia; but the time is by some placed in the age of the patriarchs, and by others, after the Babylonish captivity. The design of the work seems to be a justification of divine Providence, and the inculcating a submission to the divine dispensations. The scene is partly in heaven and partly on earth; the actors are Jehovah, Satan, Job, and his four friends, Eliphaz, Bildad, Zophar, and Elihu. Job, an upright man, with a family of seven sons and three daughters, with large herds and numerous servants, is suddenly, with the permission of Jehovah, and by the agency of Satan, deprived of his possessions and his children, yet submits patiently to the divine will. He is then further tried by the infliction of a sore disease, yet is silent. Three friends come to console him; but, struck with his desolate condition, they burst into lamentations, and sit down with him seven days in silence, "for they see that his grief is very great." At the end of this period, the grief of Job finally breaks out into bitter complaints. The remainder of the poem is occupied with the answers of his friends, and his replies to them, until the close, when God himself is introduced answering Job out of a whirlwind. After this event, Job lived 140 years, became richer than he had been before, and begat seven sons and three daughters. The whole poem is characterized by freshness and truth of colouring, simplicity, and dignity of manner, and loftiness and purity of sentiment. Intensity of passion is combined, in a striking manner, with deep views of the nature of man and the providence of God. Stuhlmann (*Hiob, ein religiöses Gedicht*) maintains that Moses could not have been the author of the poem, because it contains no allusions to the Mosaic doctrines; though this argument seems inconclusive, because, the scene being in Arabia, and the persons Arabian, such allusions would naturally be avoided. Doctor Good (*The Book of Job, from the Hebrew, with Notes*, London, 1812) considers Moses to be the author, and calls it a *Hebrew epic*. An Amended Version, with Notes, by Mr Noyes, was published in Boston, America, 1827. See the Introductions of Eichhorn, Rosenmüller and Jahn.

JOCASTA (also *Epicasta*); daughter of Menoeceus, sister of Creon, and wife of the Theban king Laius, by whom she had Oedipus. After having unconsciously slain his own father, Laius, Oedipus solved the riddle of the Sphinx, and received, as his reward, the hand of Jocasta, his own mother (of which circumstance he was ignorant). After the error was discovered, Jocasta hanged herself in despair. See *Oedipus*.

JODELLE, ETIENNE, born at Paris, 1532, wrote the first regular tragedies and comedies for the French stage. Among the former are *Cléopâtre captive* and *Didon*. His comedy *Eugène* was praised by Ronsard. Though Jodelle enjoyed the favour of Charles IX. and of Henry II., he died in great poverty in 1573. His works were collected by De la Motte (Paris, 1574, 4to, and Lyons, 1597, 12mo) He was one of the French Pleiads. See *French Theatre*, in the article *France*.

JECHEER, CHRISTIAN THEOPHILUS, a celebrated German scholar, was born in 1694, at Leipsic, where he studied medicine and theology (1712). In 1714, he delivered lectures, in which he showed himself an adherent to the philosophy of Leibnitz and Wolf. In 1732, he was made professor of history; in 1735 doctor of philosophy; and in 1742, librarian of the university. He died in 1758. His *Allgemeines Gelehrten Lexikon* (Leipsic, 1750 et seq., 4 vols.) is still valuable. Adelung brought down a supplement to this work (in 2 vols. 4to., Leipsic, 1784) to the letter I, which Rotermund of Bremen has continued.

JOEL, one of the twelve minor prophets, the time and place of whose birth are not known. From his style and poetical language, most critics place him in the golden age of Hebrew literature. Tradition makes him a contemporary of Hosea and Ezekiel, because he is placed between them in the canon. He describes a dreadful desolation of the country by grasshoppers (whether these signify an army, or really grasshoppers, commentators disagree), and finishes with a picture of better times, (the destruction of the Chaldeans), and a call upon the Deity for vengeance. His imagery is often imitated in the Apocalypse: He was always reckoned among the canonical writers, and is quoted in the New Testament (*Acts* ii. 17), which is a proof of his canonical authority at that time. Conjectures respecting his country and age are collected from the rabbins in Carpsovius's *Introd. in F. T.* p. 302, from which it appears he lived in Judah, because his writings relate to Judah and Jerusalem.

JOHANNES SECUNDUS (the bibliographical name of John Everard, a celebrated Latin poet) was born at the Hague, 1511. His father was a distinguished lawyer, who was president of the supreme council of Holland at Mechlin, during the reign of the emperor Charles V. At Bourges, where John studied law under Alciatus, he received a doctorate; but literature had more attractions for him than jurisprudence. He became acquainted with some poets of the age, and his intercourse with them tended to strengthen his predilection for works of imagination. He also distinguished himself by his skill in painting, sculpture, and engraving; but he was most indebted for his fame to his poetical works. For the improvement of his talents, he travelled to Italy, and thence to Spain, where he became secretary of cardinal Tavera, archbishop of Toledo, by whose advice he attended Charles V. on his journey to Tunis. The weak state of his health, however, did not permit him to endure the hardships of war, and he returned to the Netherlands, where he died, at Utrecht, in 1536, of a malignant fever. Few modern Latin poets have left us such pleasing amatory poems as his. The Kisses of Johannes Secundus are best known. His works, consisting of elegies, odes, epigrams, and miscellaneous poems, were published by his brothers, Nic. Grudius and Andr. Marius (who were likewise distinguished as poets), and have gone through many editions. One of the latest is that of 1771 (Leyden), with a French translation. The Kisses have been repeatedly translated into English, German, and French.

JOHANNESBERG, or BISCHOFFSBERG; a village and beautiful castle, built (between 1722 and 1732) on a hill in the Rheingau (Nassau), formerly belonging to the bishop of Fulda, under the jurisdiction of the elector of Mentz. It is celebrated for its excellent Rhenish wines. The best is made on the castle hill itself. In 1807, the vineyards and castle were given by Napoleon to marshal Kellermann. In 1816, the emperor of Austria gave them to prince Metternich, on condition of receiving

a tenth part of the produce. Sixty-three morgen to morgen is somewhat less than an acre) yield annually about 32,500 bottles, worth from 23,000 to 24,000 guilders. Good years yield double this quantity, exclusive of a quantity of less valuable wine. The cultivation of the vineyards which produce this wine is expensive, and the profit not great, though it is high. In 1809, a bottle of the best quality cost four guilders on the spot, and the wines of 1779 to 1783, and that of 1801, were sold for twelve guilders a bottle. The view from the mountain is one of the finest on the Rhine. The eye wanders over the charming Rheingau, with its numberless villages, seats and convents, hills with their castles, and the noble river with its islands.

JOHN THE BAPTIST was born six months before Jesus (their mothers were relations), of a Levitical family in Judea, and his birth was attended with circumstances (*Luke*, chap. i.) which marked him out as one chosen by God to accomplish the divine purposes. He chose the austere course of life suited to a person dedicated to God, and by his early simplicity in food and dress, by his solitary meditations on, and deep knowledge of, the spirit of the Holy Scriptures, obtained that independence and strength of mind, which made him the object of universal admiration, when he appeared in the character of a prophet. His teachings were earnest exhortations to repentance and preparation for the kingdom of heaven, which he announced to be at hand. His preaching, as recorded in the Gospels, was severe and powerful. He proclaimed himself the harbinger of a greater, who should come after him, and fulfilled his mission to prepare for him the way, with a zeal equalled only by his self-denial and humility. He baptized many converts to his doctrine, and obtained respect among all classes, by the contrast of his severe virtue with the corruption of the times. When the higher mission of Jesus was made known, at the time of his baptism in the Jordan, John pointed his disciples to this new master, and saw, without envy, his own words fulfilled—"He must increase, but I must decrease." He coveted no fame, and wished no further success. He desired only to maintain the right of speaking the truth, and fell a victim to his boldness. To gratify a vindictive woman, Herod Antipas, tetrarch of Galilee, caused him to be beheaded in prison. A number of his disciples continued faithful to him till death, and are said to have established the still existing sect of *Sabians*, or *St John Christians*, in Persia, distinguished for their veneration of John the Baptist. See *Sabians*.

JOHN THE EVANGELIST is one of the most pure and lovely characters of Christian antiquity. In his youth, he left his nets at the call of Jesus, and from that time followed his divine teacher with unchanging fidelity. Not only on his journeys was he always with him, and in all conditions his most confidential friend, but, even when the other disciples fled, he accompanied him to the judgment-seat; and under the cross, his expiring Lord pointed him out to Mary, as one who was to stand in the place of a son and protector to her. Hence he was called emphatically the *disciple whom Jesus loved*. The gentleness and tenderness which breathe through the writings of John, adapted him peculiarly to understand all the feelings of his Lord. He shared the labours and sufferings of the apostles, lived in Ephesus, was for a time an exile in Patmos, perhaps resided in Rome, and finally died at an advanced age, in the bosom of the Ephesian church, which was dearest of all to his heart. St Jerome gives a very affecting account of the last years of his life. As the infirmities of age made him unable to address the church in a systematic discourse, he always desired to be conveyed

to the assembly, and, as often as he came, addressed them thus:—"Children, love one another." Being asked, at length, why he always repeated this exhortation, with nothing new, he answered, "Because it is the precept of the Lord; and if this is fulfilled, it is enough." John was the author of one of the Gospels, of the book of Revelation, and of the three Epistles which bear his name.

JOHN. Besides the apostle, there are many saints and martyrs of this name:—

1. *St John*, a warrior in the fourth century, who encouraged Athanasia, with her three daughters to brave martyrdom. He was himself beheaded.

2. *St John of Nicomedia*, who was skinned and tortured with salt and vinegar, by order of Diocletian, because he tore down the imperial edict which ordered the imprisonment of all priests, and required them to embrace paganism.

3. *St John the Alms-giver* was born in the island of Cyprus in the sixth century. He was made patriarch of Alexandria, and spent every thing he had for the poor. His day is January 23; with the Greeks, November 11.

4. *St John of Damascus*, or *Johannes Damascenus*, in the dispute concerning the worship of images, defended the practice, against Leo Isauricus and Constantinus Copronymus. He died in 780, in a convent. His day is May 6; with the Greeks, November 29. The most complete edition of his works was published by Le Quien, 2 vols., Paris, 1512, folio. Several of his works have never been printed.

5. *St John of God (Joannes a Deo)*; born at Monte Mayor el Novo, in the province of Alentejo, in Portugal, in 1495, of poor parents. While keeping a shop in Granada, being affected by a sermon of John of Avila, he gave all his property to the poor, and became his pupil. He displayed so much fanaticism, that he was thought to be mad, and carried to an hospital; but being soon released, he established an hospital himself, which he maintained by alms. He founded a convent, from which originated the Hospitalers or Brothers of Charity. He practised the greatest severity towards himself. The bishop of Tuy, who came to Granada, gave him the name of *John of God*, which he retained. He died in 1550, and, in 1680, pope Urban VIII. canonized him.

6. *St John Chrysostomus*. See *Chrysostom*.

7. *St John Nepomuk*. See *Nepomuk*.

There are, besides, many martyrs and monks bearing the name of *John* and *St John*.

JOHN; the name of twenty-two or twenty-three popes, the last of whom died in 1419. That no subsequent pope has called himself John, is probably owing to the polluted character of several of the name, and particularly the public condemnation of the last for atrocious crimes. Among these pontiffs are the following:—

*St John (John I.)* succeeded Hormisdas in 523, and was a friend of Boethius, who dedicated to him several of his works. Theodoric sent him to Constantinople, to induce the emperor Justin to adopt milder measures towards the Arians. Though John was received with uncommon pomp, his mission was fruitless, and on his return Theodoric threw him and his companions into prison, where he died in 526. His day is May 27. Felix IV. succeeded him.

*John VIII.*, or *Johanna Papiasa*. See *Joan*, the *papasa*.

*John XI.*; son of Marozia and the pope Sergius III. He ascended the papal chair in 931, though very young, by the influence of his mother, who governed Rome. Marozia, after the death of her husband Guido, married Hugh, king of Lombardy,

who insulted Alberic, son of Marozia and Guido. Alberic revolted, and imprisoned Marozia and the pope, who died in prison in 936. Leo VII. succeeded him.

*John XII.*, son of Alberic and grandson of Marozia, though an ecclesiastic, succeeded to the dignity of his father, a patrician of Rome, and, in 956, after the death of Agapetus II., possessed himself of the tiara, though only eighteen years old. He was the first pope who changed his name on his accession to the papal dignity. He applied to the emperor Otho I. for assistance against Berengarius II., crowned the emperor, 962, and swore allegiance to him, but soon after revolted against Otho, who caused him to be deposed by a council, in 963, and Leo VIII. to be elected. On Otho's death, in 964, John returned, and died in the same year. He polluted the papal see by the most revolting licentiousness. Benedict V. succeeded him.

*John XIII.*; made pope in 965 by the influence of the emperor, for which the nobles of Rome hated and expelled him. Otho II. restored him to Rome, and was crowned by him. He died in 972. According to Baronius, he introduced the custom of consecrating bells.

*John XV.*; a Roman, elected in 985. He was the first who solemnized a formal canonization (of Ulric, or Udalric, bishop of Augsburg) in 993. He settled the disputes between king Ethelred of England and Richard of Normandy. He induced Otho III. to assist him against Crescentius, but died whilst the former was besieging the castle of St Angelo, in 996.

*John XVIII.*, or *XIX.* (if John XVI. is counted, which Baronius does not do); elevated to the throne in 1004. We mention him merely because a union is said to have been effected between the Eastern and Western churches, under his pontificate; and, in the mass, besides the name of the pope, that of the patriarch of Constantinople is said to have been mentioned.

*John XXI.*, or *XXII.* (James of Ossa), a native of Cahors, chancellor of Robert, son of Charles II. of Naples, was archbishop of Avignon, and was elected pope at Lyons in 1316, after the death of Clement V. He resided at Avignon, but had many adherents in Italy. He is important in German history, on account of the active part he took in the disputes of the emperors Louis of Bavaria, and Frederic of Austria. He was entirely in the interests of France. He died in 1334, after having been once deposed by Louis, who caused Nicolas V. to be elected in his stead. The Clementines and the Extravagantes (see *Canon Law*, and *Corpus Juris*) prove his learning. As a theologian, he held a heretical opinion respecting the beatific vision of God, maintaining that Mary and all the blessed could not enjoy it until after the final judgment, and was on the point of being deposed by a general council on that account. He established several bishoprics and archbishoprics in France, which increased his revenues, so that he was enabled to leave immense treasures, which were not all well acquired. He fixed the festival of the Holy Trinity on the Sunday after Whitsuntide. Benedict XII. was his successor.

*John XXII.*, or *XXIII.* (Balthasar Cossa), born in Naples, was a pirate in his youth, afterwards became an ecclesiastic, studied at Bologna, was made a *doctor juris*, and was elected pope in 1410, by the council of Pisa, after the death of Alexander V., on condition that, if Gregory XII. and Benedict XIII. would resign, he would also retire, to end the schism. He summoned the council of Constance, demanded by the emperor Sigismund, in 1415, where he appeared in person, and confirmed his resignation,

March 2; but, March 20, he fled, secretly, from Constance to Schaffhausen, and revoked his resignation. He was cited before the council, but not appearing, he was suspended, and finally deposed, May 29, for seventy crimes (malice, tyranny, incest, licentiousness of all kinds, intercourse with his brother's wife and with 300 nuns, simony, murder, &c.), attested by thirty-seven witnesses. He was confined in the castle of Gottleben, near Constance. The elector of the Palatinate was then charged with his safe keeping, and he remained at Manheim and Heidelberg, under custody. Four years after, he was released, on the payment of 30,000 gold guilders, went to Italy, and threw himself at the feet of pope Martin V., in Florence, who pardoned him, and made him cardinal, bishop of Tuscoli, and dean of the college of cardinals. He died soon after, in November, 1419.

JOHN, king of England, born in 1166, was the youngest son of Henry II., by Eleanor of Guienne. Ireland being intended for his appanage, he was sent over, in 1185, to complete the conquest; but such was the imprudence and insolence of himself and his courtiers, that it was found necessary to recall him. Although his father's favourite, he joined his brother Richard in his last unnatural rebellion, and partook with him the curse pronounced by the heart-stricken king and parent on his deathbed. He was left without any particular provision, which procured for him the name of *Sans Terre*, or Lackland; but Richard, on his accession, conferred on him the earldom of Mortaigne, in Normandy, and various large possessions in England, and married him to the rich heiress of the earl of Gloucester. This kindness did not prevent him from forming intrigues against his brother, in conjunction with Philip of France, during his absence in Palestine; but Richard magnanimously pardoned him on his return, and left him his kingdom, in preference to Arthur of Brittany, the son of his elder brother, Geoffry. So imperfectly was the rule of primogeniture then established in this country, that no disturbance whatever ensued, although the French provinces of Anjou, Touraine, and Maine declared for Arthur, who was taken under the protection of the king of France. A war ensued, in which John recovered his revolted provinces, and received homage from Arthur for the duchy of Brittany, inherited from his mother. In 1200, he married Isabella of Angouleme, after divorcing himself, on some pretence, from his first wife. In 1201, some disturbances again broke out in France, whither he led another expedition; and the young Arthur, having joined the malcontents, was captured, and confined in the castle of Falaise, whence he was subsequently removed to Rouen, and never heard of more. The manner of his death is not certainly known; but it was generally believed that John stabbed him with his own hand, and he now became the object of universal detestation. The states of Brittany summoned him to answer the charge of murder, before his liege lord, king Philip; and, upon his refusal to appear, the latter assumed the execution of the sentence of forfeiture against him, and in this manner the whole of Normandy was recovered by the French crown, after its alienation for three centuries. John laid the fault of his disgrace upon his English nobles, whom he harassed by fines and confiscations; but, after some ineffectual attempts, he was obliged to acquiesce in a truce in 1206. The pope at this time was the haughty and able Innocent III., who, in consequence of a contested election for the see of Canterbury, nominated a creature of his own, cardinal Stephen Langton. John, highly enraged, acted with his usual haste and folly, and displayed so much contempt for the papal authority, that

Innocent laid the whole kingdom under an interdict. This quarrel lasted some years, and the king, by his tyranny, depriving himself of the support of his nobles, was perplexed on every side. In order to give some lustre to his degraded administration, he undertook expeditions into Scotland, Wales, and Ireland, in which he was successful, and, in particular, quelled all opposition to his authority in the last country. In the mean time, the court of Rome communicated the king, personally, and formally absolved his subjects from their allegiance. Philip of France was again ready to put the sentence against John into execution, and prepared an expedition to the ports of Picardy, which, however, the latter was enabled to oppose. So much disaffection, nevertheless, prevailed, that Pandolph, the pope's legate, induced him not only to receive Langton, as archbishop of Canterbury, but abjectly to resign his kingdom of England and Ireland to the holy see, in order to receive them again as its vassal, with absolute. This ignominious compact was executed at Dover, in May, 1213; and the pope, now regarding England as his own, and jealous of the aggrandizement of Philip, required the latter to desist from hostilities against a country under the protection of the see of Rome. Philip received this mandate with great indignation, but, in consequence of a victory over his fleet, was gradually brought to reason. Flashed with this success, John resolved to endeavour to recover his continental dominions; but the English barons declined the service. In the next year, however, he carried over an army to Poitou; but, after some partial successes, was obliged to return in disgrace. John had, by this time, rendered himself the object of such universal contempt and hatred, that his nobles, who had long felt aggrieved by the usurpation of their sovereigns, and of the reigning one in particular, determined to seize upon so favourable an opportunity to control his power, and establish their privileges. Langton produced to them a copy of the charter of rights granted by Henry I., and, at a general meeting in London, in January, 1215, they laid their demands before the king, which he attempted to elude by delay. In the mean time, he sought to ingratiate himself with the clergy and the pope, with whom he lodged an appeal against the compulsory proceedings of the barons. The politic papal who found it his interest to support a sovereign who had so far humbled himself, declared his disapprobation of their conduct; but, little moved by the declaration, the latter assembled in arms at Oxford, where the court then was, and, choosing a general, immediately proceeded to warlike operations. They were received without opposition in London, which so intimidated the king, that he consented to sign such articles of agreement as they thought fit to dictate. Such were the steps which produced the *Magna Charta*, which was signed by John at Runnymede, on the banks of the Thames, June 19, 1215. By the charter—the basis of English constitutional freedom—not only were the nobles protected against the crown, but important privileges were granted to every order of freemen. The passive manner in which John yielded to these restrictions of his power, indicated a secret intention of freeing himself from his obligations. In order to lull the barons into security, he dismissed his foreign forces, but, in the mean time, was secretly employed in raising fresh mercenaries, and in seeking the concurrence of the pope, who issued a bull, annihilating the charter, as extracted from his vassal, contrary to the interests of the holy see. He even forbade John to pay any regard to its conditions, and pronounced a sentence of excommunication on all who should attempt to enforce it. Thus furnished with spiritual and temporal arms, the

king left his retreat, and carried war and devastation through the kingdom. His barons, taken by surprise, could make no effectual resistance, and, despairing of mercy from John, sent a deputation to France, in which they offered the crown of England to the dauphin Louis. Philip gladly accepted the proposal, and Louis, with a fleet of 600 vessels, landed at Sandwich, and proceeded to London, where he was received as lawful sovereign. John was immediately deserted by all his foreign troops, and most of his English adherents; but the report of a scheme of Louis for the extermination of the English nobility, arrested his progress, and induced many to return to their allegiance. While the king's affairs were beginning to assume a better aspect, he had the misfortune, in a march from Lynn across the sands into Lincolnshire, to lose, by the sudden flow of the tide, all his carriages and baggage. Being already in a bad state of health, this event so aggravated his disorder, that he died at Newark, in October, 1216, in the forty-ninth year of his age, and seventeenth of his reign. No prince in English history has been handed down to posterity in blacker colours than John, to whom ingratitude, perfidy, and cruelty were habitual.—Apparent gleams of vigour and energy were, indeed, occasionally manifest; but they always proved mere explosions of rage, and soon subsided into meanness and pusillanimity. His private life was stained with extreme licentiousness, and the best part of his conduct as a ruler, was the attention he paid to commerce and maritime affairs. More charters of boroughs and incorporations for mercantile pursuits date from him than from any other of the early kings, and the popular constitution of the city of London was his gift. He left, by his second wife, a family of two sons and three daughters, and had many illegitimate children.

JOHN SCOTUS. See *Erigena*.

JOHN THE PARRICIDE, or JOHN OF SUABIA, was the murderer of his uncle, the emperor Albert I. (See *Albert I.*) Himself of a mild, peaceful disposition, he would, perhaps, have endured the injustice of his uncle, who withheld from him his hereditary dominions and fief, had not his anger been fanned into a flame by the enemies of the emperor. After the perpetration of the bloody deed (in the neighbourhood of Hapsburg, May 1, 1308), the murderers took to flight; among them was John, who wandered in the monastic habit through Italy, and finally sank into such obscurity, that nothing was known with certainty of him. Rodolph of Wart was apprehended and punished by the rack on the spot where the deed was committed; the other murderers escaped, with the exception of three boys, who confessed nothing, though threatened with a cruel death, which they actually suffered. But a sanguinary revenge was taken on the relations of the murderers by Leopold, the second son of the emperor, and by Agnes, his sister, the widowed queen of Hungary. They were executed with the most terrible torments, their castles demolished, and the inhabitants slain by hundreds. More than a thousand innocent men, women, and children perished. The history of John of Suabia has given rise to the tragedy of that name, which, for more than twenty years, has been performed on the German stage.

JOHN OF PIESOLE. See *Fiesole*.

JOHN OF LEYDEN. See *Anabaptists*.

JOHN SOBIESKI, or JOHN III., king of Poland, one of the greatest warriors of the seventeenth century, was born 1629. His father, James Sobieski, equally distinguished for his virtues in peace and his courage in war, took great care to nourish the same qualities in his sons, Mark and John. The Poles had just been defeated at Pilawiecs, when

these youths returned from their travels. This misfortune only served to excite their courage. Mark fell in a second engagement with the Cossacks, on the banks of the Bog; but John, more fortunate than his brother, became successively grand marshal and general of the kingdom. Full of courage, he exposed himself, like the meanest soldier, to the greatest dangers, and when urged to take care of his person, replied, "If I follow your advice, you will despise me." He became the terror of the Tartars and Cossacks, over whom he was perpetually gaining new victories. November 11, 1673, he won the celebrated battle at Chocim against the Turks, who lost there 28,000 men. The following year, he was elected king of Poland. When the Turks had laid siege to Vienna, in 1683, he hastened thither with a Polish army, and rescued the imperial city. His cavalry was splendid, but his infantry poorly equipped. To conceal the condition of the latter, he was advised to send one of the worst clothed regiments of infantry over the river by night, to save them from the gaze of spectators. Sobieski was of a different opinion. When the regiment was on the bridge, he said to those who surrounded him, "Behold them—they are invincible; they have sworn never to wear any dress but that of enemies: in the last war, they were all clothed in the garb of Turks." On his arrival, he chose the most advantageous position, ascended an elevation to observe the disposition of the grand visier, and remarked—"He has selected a bad position. I understand him; he is ignorant, and persuaded of his own genius. We shall gain no honour from this victory." Sobieski was not deceived. The next day the Turks were driven from their camp in terror, leaving behind the holy standard of Mohammed, which the conqueror sent to the pope with the following letter: "I came, I saw, and God has conquered." On his entrance into Vienna, at the head of his victorious Poles, the inhabitants received him with indescribable enthusiasm. They pressed around to embrace his feet, to touch his garments or his horse, and proclaimed him their saviour and deliverer. He was moved even to tears, and, under the strong impulse of his feelings, called this the happiest day of his life. In 1693, he was attacked by a dangerous sickness, and was doomed to witness that dissension which usually attends the election of a king in Poland. Foreign enemies united with domestic factions. Sobieski was no longer in a condition to quiet the disturbances, and the moment was fast approaching which was to deprive him at once of his life and his throne. The queen wished him to make a will, and communicated her wishes through one of the bishops. He refused, asserting that, in a nation like his, party rage would prevail over all his influence. He died 1696, in the twenty-third year of his reign. Scarcely had he closed his eyes, when jealousy and envy united to stain his memory. Some reproached him with having purchased lands contrary to the laws, which forbade the king to hold any private property. Others maintained that the Christian league which he had joined against the Turks, had cost his country more than 200,000 men. Others still asserted that he was too fond of money and expensive journeys. Certainly no court was ever less stationary than his. He performed the tour of Poland every year with his queen, and visited all his estates, like a nobleman. This fault, however, if it may be called a fault, should not cast a veil over the virtues of Sobieski. He was fond of the sciences, spoke several languages, and deserved to be loved for his gentleness and affability. His three sons died without leaving any male descendants. The character of Sobieski is displayed in the *Lettres du*

*Roi de Pologne Jean Sobieski à la Reine Marie Casimire, pend. la Camp. de Vienne, trad. par le Comte Plater, et publ. par N. A. de Salcandy (Paris, 1826).*

JOHN VI., emperor and king of Portugal, Brazil, and Algarve, born May 13, 1767. On account of the mental derangement of the queen Francisca, his mother, he was proclaimed director of the government in Portugal, February 10, 1792. In 1807, he embarked for Brazil with his family, and landed at Rio de Janeiro, January 6, 1808. December 18, 1815, he raised Brazil to the rank of a kingdom, and united all his states into one monarchy. After the death of his mother, March 20, 1816, he became king. In 1790, he married the Infanta Charlotte, daughter of Charles IV. of Spain. (Respecting his son Pedro, and the revolution in Brazil, see *Pedro*.) His second daughter, Maria, first wife of King Ferdinand VII. of Spain, died in 1818; a third is the wife of Don Carlos, brother of Ferdinand. On account of the old commercial relations between Portugal and Britain, John was not in a condition to maintain a strict neutrality towards France. In 1793, he had sent the Spanish government a small body of soldiers to aid in the defence of the Pyrenees; but, after Spain had made peace (1795), and concluded an alliance (1796) with France, Portugal was treated as an enemy by both. John looked to Britain, therefore, for protection. Bonaparte at length induced the Spanish court to make an attack in earnest upon Portugal, which ended in the peace of Badajoz (January 6, 1801); Olivença was ceded to Spain, and a part of Guiana to France. After the peace of Tilsit, Napoleon, not content with the vast sum of money by which John had purchased his neutrality, required him also to close his ports against the British, to arrest all of that nation in Portugal, and to confiscate their estates. As the regent complied with the first only of these requisitions (in consequence of which a British fleet blockaded his harbours), the *Moniteur* declared that the house of Braganza had ceased to reign (see *Spain since 1808*), and an army composed of French and Spanish soldiers marched into Portugal. The prince-regent now resolved to transfer his court to Brazil, as he had been advised to do in 1800. The British ambassador, Viscount Strangford, and the British admiral, Sir Sidney Smith, facilitated the accomplishment of his design. November 26, the prince-regent appointed a junta for administering the government, and, on the 27th, the royal family embarked, passed the mouth of the Tagus on the 29th, with a fleet of eight ships of the line, four frigates, four brigs, and twenty other vessels, in sight of the advance-guard of Junot's army, which entered Lisbon the next day. December 1, the anniversary of the elevation of the house of Braganza, the ensigns of Braganza were succeeded by the French eagle. An earthquake and a storm, which the Portuguese fleet encountered in the view of the city and the enemy, completed the submission of the Portuguese. From Rio de Janeiro, May 1, 1808, the prince-regent declared all treaties with France and Spain null, and formed a closer union with Britain, which, powerfully supported by the bravery of the Portuguese army and the ardour of the people, recovered for him the possession of his European kingdom. Marshal Beresford continued to exercise an important influence on the affairs of Portugal, till August, 1820, when, by the convocation of the cortes, a new political system was established. In America, the Portuguese also recovered the portion of Guiana which they had lost, and occupied French Guiana; the latter, however, was restored to France in 1817. Meantime, the enlightened ministry of the prince regent carefully attended to the improvement of Brazil. The in-

quisition was abolished, religious freedom introduced, the evils of slavery diminished, and European artists, manufacturers, merchants, and agriculturists, encouraged to settle in the country. A large Dutch colony, New Freyberg, was founded in 1819. John took part in the transactions of the cortes of Vienna. The revolution of the Spanish colonies in South America (perhaps the refusal of Spain to restore Olivença) led the court of Rio de Janeiro to occupy Monte-Video, and the left bank of the La Plata. Spain had recourse to the intervention of Austria, Russia, Prussia, and Great Britain, whose declaration, directed to the marquis of Aguiar, Portuguese secretary of state for foreign affairs (Paris, March 26, 1817), induced the court of Brazil to evacuate Monte-Video, on condition that Brazil should be restored. A treaty was then concluded with Buenos Ayres, and the quarrel with Arago (q. v.) continued till 1820. A conspiracy against the existing government was discovered at Lisbon in 1817, and suppressed by the execution of those engaged in it. After this, the freemasons were persecuted more severely than ever. In consequence of the Portuguese revolution and the convocation of the cortes, 1820, which the monarch recognised as lawful, he returned, in 1821, to Portugal; the prince remained in Brazil. This vast country separated itself entirely from the mother country, where an absolute government was, in the mean time, established. John was incompetent to unite the constitutionalists and royalists. He was himself a danger of falling a victim to the intrigues of the latter, when he was rescued by a British vessel at the Tagus. Portugal and Brazil also assumed a hostile attitude; but, August 29, 1825, by the mediation of Britain, John VI. concluded a treaty with his son, the emperor Pedro I. of Brazil, in which he acknowledged that country as an independent kingdom, wholly separate from Portugal, and he was an emperor, reserving for himself, personally, the use of emperor of Brazil. This good-natured monarch, who was incompetent to struggle with the wishes of his age, and the political degeneracy of his nation, died March 10, 1826, having previously appointed his daughter Isabella regent of Portugal. See *Portugal* and the *Portuguese Revolution*.

JOHN'S, Sr, or PRINCE EDWARDS ISLAND, an island in the gulf of St Lawrence, near the north coast of Nova Scotia, to which government it was once annexed, but it now has a separate government. Lon. 44° 22' to 46° 32' W.; lat. 45° 46' to 47° 11' N. It is 117 miles long, from north east to south-west, about twenty in average breadth; population, about 5000; chief towns, Charlotte's Town (the capital), George Town, Prince's Town, &c. The north and south coasts are much indented with bays. It is well watered, the soil generally fertile, and the river abundant with fish, as salmon, trout, and eels. It was taken from the French by the British, in 1755, when it had 10,000 head of black cattle, and several of the farmers raised 12,000 bushels of corn annually. When possessed by the French, it was so much improved as to be called the *granary of Canada*.

JOHN'S, Sr, a river of New Brunswick, which rises in Canada and the northern part of Maine, waters the north-east part of Maine, flows south-west through New Brunswick, and runs into the bay of Fundy, on the west side of the city of St John's. It is 350 miles long; the tide flows up about 200 miles; it is navigable for boats 200 miles, and for sloops of fifty tons eighty miles. This river and its branches water a large tract of excellent country, much of which is settled. About thirty miles from its mouth commences a fine level country of rich meadow lands, well clothed with timber and water.

pine, beech, elm, maple, and walnut. The river furnishes a great quantity of salmon, bass, and sturgeon; and it is the common route to Quebec. About a mile above the city of St John's, is the only entrance into this river. It is about eighty or 100 yards wide, 400 yards long, called the *falls* of the river. It being narrow, and a ridge of rocks running across the bottom of the channel, on which there are not above seventeen feet of water, it is not sufficiently spacious to discharge the fresh waters of the river above. The common tides here rising about twenty feet, the waters of the river, at low water, are about twelve feet higher than the waters of the sea. At high water, the waters of the sea are about five feet higher than those of the river; so that, at every tide, there are two falls—one outwards and one inwards. The only time of passing with safety, is when the waters of the river and of the sea are level, which is twice in a tide, and continues only about twenty minutes each time.

JOHN, Sr, CHRISTIANS OF. See *Subiana*.

JOHN, Sr, KNIGHTS OF. The knights of St John, or hospitalers of St John, afterwards called *knights of Rhodes*, and, finally, *knights of Malta*, were a celebrated order of military religious, established at the commencement of the crusades to the Holy Land. As early as 1048, some merchants from Amalfi, in Naples, established a church at Jerusalem, and built a monastery, which they dedicated to John the Baptist. It was the duty of the monks, who were called *brothers of St John*, or *hospitalers*, to take care of the poor and sick, and, in general, to assist pilgrims. This order, which gradually obtained important possessions, at the beginning of the twelfth century, was regularly instituted as a military order by the principal, Raymund du Puy, retaining all their former laws. Besides the performance of their vows of chastity, obedience, and poverty, it was their duty to aid in defending the church against infidels. Raymund also divided the order into three classes—knights (who should bear arms), chaplains (regular ecclesiastics) and servants (*serventi d'armi*), whose duty it was to take care of the sick and accompany pilgrims. This order long maintained itself against the arms of the Turks and Saracens by union and courage; but, in 1191, it was driven from Palestine. Upon this, the knights conquered Cyprus, but soon lost it again, and established themselves, in 1309, on the island of Rhodes, where they remained upwards of 200 years. This island was vigorously defended against Mohammed II., by Pierre d'Aubusson (grand master, who died 1503). Driven thence by the sultan Soliman II. (1522), the knights went to Candia, then to Venice, Rome, and Viterbo, and especially to Nice, Villa Frasca, and Syracuse, till Charles V. (1530) granted them the islands Malta, Gozzo, and Comino, on condition of perpetual war against the infidels and pirates, and the restoration of these islands to Naples, if the order should succeed in recovering Rhodes. From this period, they were commonly called *knights of Malta*. In 1565, under the command of Lavalette (who died 1568), they repelled a violent attack from Soliman II. with great loss. After this, they continued their naval battles with the Turks till modern times, and saved themselves from ruin, in various wars with the Porte, only by their unyielding courage. In 1760, however, they would doubtless have been overpowered but for the interposition of the French. After that, their naval expeditions were seldom any thing more than mere show. The chief of this order,

which had great possessions in almost every part of Europe, was called *grand master of the holy hospital of St John of Jerusalem*, and *guardian of the army of Jesus Christ*. He was chosen by vote, and lived at La Vulette, in the island of Malta. He was addressed by foreign powers with the title of *altezza eminentissima*, and received annually 6000 crowns from the treasury of the order, together with all the revenues from the three islands, so that his annual income may be estimated at nearly a million guilders. The secular power was principally in his hands, but even here he was limited by the *governors of the various languages*, so called, who gave laws, fixed taxes, &c. The spiritual power (that is, the immediate affairs of the order) was exercised by the chapter, which consisted of eight *ballivi conventuali*, and in which the grand master presided. The principal offices in the order were held by the pillars (*piliere*) of the eight languages, into which the knights were divided, according to their respective nations. The languages were those of Provence, Auvergne, France, Italy, Arragon, Germany, Castile, and England. From these languages, the *ballivi conventuali* above-mentioned were chosen, and their lands were divided into priories, these into *bailliages*, and these again into *commanderies*. Of the priories, the German had the preference, and was called the *grand priory*. It was filled by the grand prior of Germany, or the master of the knights of St John throughout Germany, who was a prince of the empire, and resided at Heitersheim, a city and castle in Brisgau, now in the circle of Treisam, in Baden. The master of the knights of St John was subject to the grand master at Malta. He himself had the jurisdiction over Brandenburg, Hungary, and Bohemia. Austria, Bohemia, and Moravia formed, besides, a separate grand priory of the German language. The last master of the knights of St John in Germany, or grand prior of Heitersheim, a count of Reichenbach-Fouxmaigne (or the baron Rink of Balenstein), by the peace of Presburg and the formation of the confederacy of the Rhine, lost all his possessions in West Suabia, which fell into the hands of the grand duke of Baden. Of the eight languages above-mentioned, the English became extinct in the sixteenth century; the three French languages perished during the revolution; those of Castile and Arragon were separated from Malta at the peace of Amiens, and the Italian and German languages have since been abolished. Thus the order of St John is to be regarded as extinct, and its restoration is the less to be looked for as the island of Malta has been formally ceded to Britain. The Prussian order of knights of St John, founded by Frederic William III., and which is a royal order, can be considered only as a memorial of an order venerable for its antiquity and its services. (See *Prussia*.) The knights of St John observed the rules of the order of St Augustine. The Protestants, however, were not bound to celibacy. Every member was required to be of good family. The knights who could bring indubitable evidence of noble ancestry were called *cavalieri di giustizia* (knights by right). Those, on the contrary, who could not prove their nobility, but were, nevertheless, received on account of their merits, were called *cavalieri di grazia* (knights by favour). The duty of each knight—to take the field at least three times against the infidels, or the pirates of Barbary—was rarely performed in recent times, and, by the peace of Amiens, all hostilities against the Turks were forbidden. In peace, these knights wore a long black mantle; a gold cross of eight points, enamelled white; in war, they wore a red jacket or tabard, charged with a full white cross. Only in spiritual concerns was the order subject to the pope: in all temporal ones, they enjoyed unlimited

sovereignty. Their naval force, in 1770, consisted of four galleys, three galiots, four ships of sixty, and two frigates of thirty-six guns, with various smaller vessels. When Malta was unexpectedly attacked by Bonaparte, June 8, 1798, the island capitulated without resistance. (See *Hampesch*, and *Malta*). In 1800, the British reduced it by famine, and it has been, ever since, in our hands. At the peace of Amiens (1802), it was stipulated that the island should be restored to the knights, under the guarantee of a neutral power; but as our government continued to entertain apprehensions lest the French would retake Malta, and thus destroy our superiority in the Mediterranean, we continued in possession of it. Dec. 16, 1798, the order had chosen for their grand master the Russian emperor, Paul I., who declared the capitulation of 1798 an act of treachery, and took the knights of St John under his protection. This choice met with much opposition, even from the pope himself. After the death of Paul I. (Feb. 9, 1805), the pope appointed an Italian (Tommasi) grand master, and, on his decease, the grand chapter chose Caracciolo. The chief seat of the order had been, hitherto, Catania in Sicily. In 1826, the pope permitted the chapter and the government to remove their seat to Ferrara. Before the French revolution, the number of knights of this order was estimated at 3000. For further information, see *Malta*.

JOHN BULL, the sportive, collective name of the English people, was first used by dean Swift.—*Jonathan*, or *brother Jonathan*, is applied, in the same way, to the people of the United States.—The Irish *Paddy* (from *Patrick*), the Scotch *Sauwey* (from *Saunders*, which comes from *Alexander*), are more particularly applied to individuals than to the Irish and Scotch people collectively.—*Yankee* (q. v.), also, signifies a single American, particularly a native of the Eastern States; whilst *Uncle Sam*—a colloquial and rather low expression, derived from *U. S.* the abbreviation of *United States*—is used to denote the government of the United States collectively.—*John Bull* is used by the British themselves to convey the idea of an honest, blunt, but in the main good-natured, character. With foreigners, it is used to express the insular peculiarities and prejudices of the nation, and their inability to accommodate themselves to the circumstances of foreign countries.

JOHN DORY. See *Dory*.

JOHN'S FIRE. Among the Romans, the festival of Vesta was celebrated by kindling a fire, with dancing and rejoicings. In the early periods of Christianity, the ancient pagan rite was perpetuated of setting fire to consecrated herbs, or laying them upon the coals. This ceremony was called *John's fire*, or the *Aerb fire*. Superstitious people believed that the smoke of these herbs would keep off the devil, storms, and witches, or preserve from those evils the houses where they were burnt, for the succeeding year.

JOHNES, THOMAS; an English gentleman, who distinguished himself by the cultivation of literature. He was born in 1748, studied at Oxford, made the tour of Europe, and collected a noble library, to which he added a typographical establishment, whence proceeded the works on which his literary reputation is founded. They consist of splendid editions of the chronicles of Froissart and Monstrelet; Joinville's memoirs of St Louis; the travels of Bertrand de la Brocquiere in Palestine; and Stephen Palaye's life of Froissart; all translated by himself from the French. He died in April, 1816.

JOHNSON, SAMUEL, a clergyman distinguished for his zeal in the cause of civil liberty, was born in 1649. During the time that lord Russell, with his conjutors, was promoting the bill for excluding the duke of York, he published a tract entitled *Julian the*

Apostate, meant as a refutation of the doctrine of passive obedience by doctor Hicke. For this book he was prosecuted in the court of king's bench, and sentenced to fine and imprisonment. Inability to pay the fine caused him to be confined in the rules of the prison, where he was privately assisted by the benefactions of his political friends, and continued to disperse several pieces against popery. In 1656, when the army was encamped upon Hounslow Heath, he wrote An humble and hearty Address to all the English Protestants in the present Army. For this production he was committed to close custody, tried before the king's bench, and condemned to stand in the pillory in three places, to pay a fine of 500 marks, and to be publicly whipped from Newgate to Tyburn. Before the execution of this disgraceful sentence, he was deprived of his orders. He bore all these indignities, including the whipping, which was inflicted with great severity, with the firmness and alacrity of a martyr, which he was deridingly called; and, happy, some informality in the process of degradation preserved to him his living. With unbroken spirit he continued to employ his pen in the same cause, until the revolution changed his situation. He received a present of £1000, and a pension of £200 per annum, for the life of himself and his son. He continued to write in favour of king William with much strength of reason, but with a degree of acrimony which produced some personal annoyance from opposing partisans, which had little effect upon a man of undetermined a spirit. Notwithstanding his attachment to the new government, he freely censured many of its acts, and even contended for annual parliaments. He died in 1703. His works were published in 1709, 1 vol., folio, and re-edited in 1713.

JOHNSON, SAMUEL, LL. D.; one of the most distinguished English writers of the eighteenth century. He was born at Lichfield, in Staffordshire, in 1709, of which city his father was a small bookseller. He was the elder of two sons, the younger of whom died in his infancy; and he inherited from his father a robust body and active mind, together with a scrofulous taint, which impaired his sight and hearing, and a strong disposition to morbid melancholy. He also derived from the same source a marked attachment to high church principles, and a decided predilection for the family of Stuart. He received his early education, partly at the free-school of Lichfield, and partly at Stourbridge, in Worcestershire; and, on returning from school, he remained two years at home. Having acquired reputation from his exercises, particularly of the poetical class, a neighbouring gentleman of the name of Corbet offered to maintain him at Oxford as companion to his son. He was accordingly entered of Pembroke college in 1728, being then in his nineteenth year; but he exhibited no marked attention to his studies in the first instance, and the state of indigence into which he fell by the neglect of the promised assistance, on the part of the family by whose advice he was sent to Oxford, produced a degree of mental anxiety, which he is said to have attempted to conceal by affected frolic and turbulence. Still he acquired credit by occasional poetical compositions in the Latin language; but, after all, left Oxford, after a residence of three years, without taking a degree. About this time, according to his own account, he received a strong religious impression from the perusal of Law's Serious Call to a devout and holy Life. Soon after his return to Lichfield, his father dying in very narrow circumstances, he was constrained to accept the situation of usher at the grammar-school of Market Bosworth. This situation his impatience under the haughty treatment of the principal soon induced him to quit; and he passed some time as a guest with a medical school-

fellow, settled at Birmingham. Here he wrote essays for one of the journals, and translated from the French father Lobo's Travels in Abyssinia. Returning to Lichfield, he published proposals for the republication of the poems of Politian, with a life, and a history of modern Latin poetry, which prospectus was but little attended to. Disappointed in this scheme, he offered his services to Cave, as a contributor to the Gentleman's Magazine, which, however, was but a slight step towards a maintenance; and, in 1735, he sought to improve his condition by a marriage with Mrs Porter, the widow of a mercer. Her fortune of £800 was a dowry of some moment to a suitor in the station of Johnson; and the fact of her being twice his own age, and possessed of no pretension to personal attraction, renders his subsequent description of this union as a "love match on both sides" the more extraordinary. He now took a large house at Edial, with a view to take pupils and boarders, but the plan did not succeed; and, after a year's trial, he resolved to seek his fortune in London, in company with one of his few pupils, the celebrated David Garrick. In March, 1737, the two adventurers accordingly arrived in the metropolis, Johnson with his unfinished tragedy of Irene in his pocket, and with little to depend upon but his slender engagement with Cave. At this time he became acquainted with the reckless and unfortunate Savage, and in some respects his personal conduct was unfavourably affected by the intimacy; but from irregularity of this nature he was soon recovered by his deeply-grounded religious and moral principles. His first literary production, which attracted notice in the metropolis, was his London, a Poem, in imitation of the third satire of Juvenal. He soon after made an attempt to obtain a Dublin degree of M.A., through a recommendation to Swift, in order to obtain the mastership of a free grammar-school in Leicestershire, but could not succeed. Failing in this attempt, his engagement in the Gentleman's Magazine led to a new exercise of his powers in the composition of parliamentary debates, which, being then deemed a breach of privilege, were published under the fiction of Debates in the Senate of Lilliput. The extraordinary eloquence displayed in these productions was almost exclusively the product of his own invention; but it is probable that he adhered more faithfully to the tenor of the arguments of the real speakers than to their language. He however confesses himself, that he "took care the Whig dogs should not have the best of it." His attachment to the Jacobites was also further manifested by the composition of a humorous pamphlet, in 1739, entitled the *Marmor Norfolciense*, consisting of a supposed ancient prophecy, in Latin monkish rhymes. For some years longer, the Gentleman's Magazine received the chief of his attention. For this miscellany, he composed several excellent biographical articles, and, in 1744, published his celebrated Life of Savage separately. In 1747, after a number of abortive projects, he sent out his plans for an English Dictionary, in an admirably composed pamphlet, addressed to the earl of Chesterfield, who, however, concerned himself very little in the success of the undertaking. The time that he could spare from this compilation, which has been justly accounted a wonderful exertion of industry, was allotted to various literary avocations. In the same year, he furnished Garrick with his admirable prologue, on the opening of Drury-lane theatre; and, in 1749, published another admired imitation of Juvenal, which he entitled the Vanity of Human Wishes. In the same year, his tragedy of Irene was produced at Drury-lane theatre, under the auspices of Garrick. It was performed thirteen nights with but moderate applause, and Johnson, satisfied that he was not formed to excel in

the drama, wisely gave up the endeavour. In March, 1750, appeared the first paper of the Rambler, the gravity of the tone of which, notwithstanding its acuteness of observation, richness of illustration, and dignity of expression, prevented it from obtaining a wide circulation as a periodical paper, although, when collected into volumes, the author himself lived to see it reach a tenth edition. A short time before the appearance of the Rambler, half deluded by his political dislike of Milton, he hastily adopted the imposture of Lauder, in his attempt to fix the charge of plagiarism on that great poet. When undeceived, however, he insisted upon Lauder's signing a formal recantation, and, possibly as some atonement, wrote a prologue to *Comus*, when acted for the benefit of Milton's grand-daughter. In the year 1755 was published his long expected Dictionary, to which his name appeared with the degree of M.A., obtained from the university of Oxford, by the good offices of Mr Warton. The approaching publication of this work Lord Chesterfield had favourably announced, some months before, in two papers of the World; but Johnson, conscious of having received no sort of support or encouragement from that nobleman during its progress, addressed to him a well-known letter, replete with pointed sarcasm and manly disdain. The Dictionary was received by the public with very general applause; and although its neglect of the northern etymologies, and the defects rendered apparent by more recent research, have somewhat lessened its original reputation, it still remains the leading work of the kind in the English language. In its progress, however, this great work had done nothing beyond merely supporting him; and it appears, from an arrest for a very trifling sum, in the year subsequent to its publication, that his necessities continued undiminished. An edition of Shakspeare, the Idler, with occasional contributions for a literary magazine, formed the desultory occupation of several succeeding years. In 1759, he wrote his celebrated romance of Rasselas, Prince of Abyssinia, which fine performance he composed in the evenings of one week, in order to defray the funeral expenses of his aged mother. At length, in 1762, the Bute administration granted him a pension of £300 per annum, which he accepted, after a short struggle against the reception of a favour from the house of Hanover. His own sarcastic definition of the word *pensioner*, in the Dictionary, was naturally enough quoted upon this occasion; but the sterling and acknowledged merits of the man formed a satisfactory apology. His advanced reputation and amended circumstances now considerably enlarged his acquaintance, and he became member of a weekly club, in Gerrard-street, Soho, composed of the most eminent men of talents of the day, and also commenced that intercourse with the Thrale family which produced him so much social enjoyment. In 1765 appeared his long-promised edition of Shakspeare, which was ushered in by an admirable preface; but the work itself did not altogether answer public expectation, owing principally to the superficial acquaintance of the commentator with the writings of the age in which Shakspeare flourished. In 1770, although his pension was given without conditions, his attachment to the monarchical side in general politics, led him to compose a pamphlet, entitled the False Alarm, in favour of the resolution of the house of commons in the affair of Wilkes—that expulsion implied incapacity of re-election. This production was followed by Thoughts on the late Transactions in Falkland's Island, against the conduct of Spain in regard to that unprofitable possession; the Patriot, written on the era of the general election, in 1774, and Taxation no Tyranny, a more considerable effort, which made its appearance in 1775, against

the arguments of the American colonists, relative to the power claimed by the mother country to tax them at pleasure. This pamphlet, although vigorously composed, was more dictatorial than argumentative, and abounding, as it did, with irritating sarcasm, did little service to the cause thus espoused. At this time, Johnson was encouraged in a view of obtaining a seat in parliament, but, meeting with no encouragement from the ministry, the scheme was dropped. In 1773, he made a tour to the Western Isles of Scotland, in company with his friend Boswell, of which he gives a highly instructive account in his *Journey to the Western Isles of Scotland*. In this production, he pronounced decidedly against the authenticity of Ossian, which sentence involved him in a broil with Macpherson. In 1775, he received the diploma of LL. D. from the university of Oxford, and soon after visited France, in company with the Thrales and Baretti. His last literary undertaking was his *Lives of the Poets*, which was completed in 1781; they were written to prefix to an edition of the works of the principal English poets, and, in a separate form, comprise 4 vols., 8vo. With an occasional exhibition of political bias, and strong prejudices, a conspicuous instance of which is supplied by the life of Milton, they form a valuable addition to English biography and criticism. The concluding portion of the life of this eminent man was saddened by the loss of many old friends, and by declining health, rendered doubly distressing in his case by a morbid apprehension of death, which neither his religion nor philosophy could enable him to bear with decent composure. In 1783, he was greatly alarmed by a paralytic stroke, and his health never wholly recovered the shock, although he lived to the 13th December, 1784. For some days previously, he retained all his horror of dissolution; but he finally died with devotional composure. This event took place in his seventy-fifth year, and his remains were interred in Westminster abbey, with great solemnity, being attended by a respectable body of eminent characters, and his statue has been placed in St Paul's cathedral.

From the numerous and copious biographical tributes to the memory of doctor Johnson, and especially that of Boswell, few persons have been made so well known to the public, either as authors or men. In the former capacity, he is more to be admired for vigour and strength, than for novelty of conception. No writer delivers moral maxims and dictatorial sentences with more force, or lays down definitions with more grave precision. He also excels in giving point to sarcasm, and magnificence to imagery and abstraction. His critical acumen, setting aside personal and political prejudices, was likewise very great; but he is utterly averse to the easy and familiar, both in his style and sentiment; the former of which made an era in English composition. The admiration of its exuberance of words of Latin etymology, and its sonorous rotundity of phrase, after having betrayed some able writers into injudicious imitation, has subsided, and the share of influence which remains has indisputably improved the general language.

As a man, doctor Johnson was, in mind as in person, powerful and rugged, but he was capable of acts of benevolence and of substantial generosity, which do honour to human nature. His strong prejudices have been already mentioned, and it is to be regretted that his admirable conversational and argumentative powers were sullied by dictatorial arrogance, and the most offensive impatience of contradiction—qualities that were unhappily heightened by the extreme deference and lavish admiration with which he was treated on arriving at the summit of his reputation.

The effect was more injurious to himself than to his hearers, as it evidently fostered the seeds of bigotry and intolerance, with which he set out in life. Upon the whole, however, both the moral and intellectual character of doctor Johnson stands very high, and so may be regarded, without hesitation, as one of the most eminent of the distinguished writers of the eighteenth century. His works were published collectively, in 11 vols., with a life of the author, by Sir John Hawkins, 1787, and in 12 vols., by Murphy, in 1792. See his life by Boswell, Hawkins, Murphy, &c.

JOHNSON, SAMUEL, first president of King's college, New York, was born at Guilford, Connecticut. He entered the college at Saybrook at about fourteen years of age, and was graduated in 1714. In 1716, a college was established, by the general court of the colony, at New Haven, and Mr Johnson was appointed tutor, though not more than twenty years old. In 1720, he became a preacher at West Haven. A short time afterwards, he became an Episcopalian, and, in 1722, went to England to obtain ordination. Here he received the degree of master of arts at Oxford and Cambridge. In 1723, he returned, and settled at Stratford, where he preached to about thirty Episcopal families in the place, and about forty in the neighbouring towns. He was treated by the people at large, as a schismatic and apostate, and continually thwarted, the object being to drive him from the country. This treatment he endured with patience and firmness. In 1743, the university of Oxford made him a doctor of divinity. In 1754, he was chosen president of the college just established at New York, and filled the office, with much credit, until 1763, when he resigned and returned to Stratford, where he resumed his pastoral functions, and continued them till his death, January, 1772, at the seventy-sixth year of his age. He was a man of great learning, quickness of perception, soundness of judgment, and benevolence. While bishop Berkeley was residing in Rhode Island, which he did two years and a half from the time of his arrival, in 1729, doctor Johnson became acquainted with him, and embraced his theory of Idealism. Doctor Johnson's publications were chiefly controversial. He also published a Hebrew and an English Grammar.

JOHNSON, SIR WILLIAM; a British military officer, who served with distinction in North America, in the middle of the last century. He was a native of Ireland, and was descended from a good family long settled in that country. Early in life, he came to America, under the care of his uncle, Sir Peter Warren, K. B., and, entering into the army, he gradually rose to the rank of colonel. In 1755, he was appointed to the command of an expedition directed against the French fort of Crown Point, where, though the main object of the undertaking was not effected, the colonel defeated a body of Indian Canadian and French troops, commanded by Baron DuRoi, who was taken prisoner. The British general was rewarded for his conduct on this occasion by a baronetcy, and a gratuity from parliament of £2000. He had settled on the Mohawk river, acquired a considerable estate, and ingratiated himself both with the American settlers and the neighbouring Indians. His ability as a negotiator was displayed in his intercourse with the latter, with whose manners and customs he was intimately acquainted. He made a treaty with the Senecas, which was concluded at his house at Johnson's hall, where he appeared April 2, 1764, as British agent and superintendent of Indian affairs for the northern parts of America, and commander of the six united nations. He died at the same place in 1774, much regretted for his private worth as well as for his abilities, which had been so usefully exerted.

in the cause of his country. He was the author of a paper on the Customs and Manners and Languages of the Northern Indians of America, published in the 63d volume of the Philosophical Transactions.

JOHNSTONE; a thriving town in Renfrewshire, situated within the abbey parish of Paisley, about three miles west from that town, and eleven from Glasgow. Fifty years ago it consisted only of one or two cottages, built near the bridge over the Black Cart river, and was hence popularly called the 'Brig of Johnstone.' It is now a considerable and flourishing town, with a population of about 7,000. It owes its rapid strides to the introduction of cotton-spinning, its situation being highly favourable for that manufacture, whether as regards the supply of water or of coal. In Johnstone and the neighbourhood, there are now upwards of twenty cotton-mills, some propelled by water, others by steam. There are also several machine manufactories, brass and iron foundries, and a public gas work. The inhabitants enjoy the benefit of a subscription library, a mechanics' institution, news-rooms, &c. The Ardsloan canal from Glasgow terminates in a basin at the east end of the town. (See article *Canal*, vol. ii. p. 7.) The census of Johnstone is taken with that of Paisley, and its population cannot therefore be accurately given.

JOHNSTONE, or JOHNSON, CHARLES, an ingenious writer, was a native of Ireland. He was born in the early part of the last century, was called to the bar, and went over to England to practise, but, being afflicted with deafness, confined himself to the employment of a chamber counsel. His success not being great in this way, he turned his attention to literature, and his first literary attempt was the celebrated *Chrysal*, or the *Adventures of a Guinea* (two volumes, 12mo), a work which attracted much attention. The secret springs of some political intrigues on the continent were unfolded in this production, which, together with smart and piquant sketches of many distinguished characters and persons claiming a share of public notice, rendered it exceedingly popular. As usual in such works, however, some truth is blended with much fiction, and although, in regard to known personages, little is absolutely without foundation, much exaggeration prevails. His exposure of the orgies of a club of fashionable profligates, held at the seat of a dissipated nobleman in Buckinghamshire, produced no small sensation at the time. He wrote other works of a similar class, in which much knowledge of life and manners is united to a considerable talent for spirited caricature. In 1782, he went to India, and became concerned in editing a Bengal newspaper. He died in Calcutta, about 1800.

JOINT, in general, denotes the juncture of two or more things. The joints of the human body are called, by anatomists, *articulations*. The suppleness to which the joints may be brought, by long practice, from the time of infancy, is very surprising. Every common posture-master shows us a great deal of this; but one of the most wonderful instances of it was in a person of the name of Clark, and famous for it in London, where he was commonly known by the name of *Clark the posture-master*. This man had found the way, by long practice, to distort many of the bones, of which nobody before had ever thought it possible to alter the position. He had such an absolute command of his muscles and joints, that he could almost disjoint his whole body; so that he once imposed on the famous Mullens, by his distortions, in such a manner, that he refused to undertake his cure; but, to the amusement of the physician, no sooner had he given over his patient, than he saw him restore himself to the figure and condition of a proper man, with no distortion about him.

JOINT-STOCK COMPANIES. Where any branch of business requires a greater capital to prosecute it with advantage than can ordinarily be furnished by an individual, or by a number of individuals actually engaged in conducting it, or where the business is attended with great risks, and may, as events turn out, be very profitable, or result in great losses, as in the case of insurance, it is desirable that the laws should give facility to the combination of the contributions of numerous persons, in great or small amounts, to make up the requisite capital. The first and most obvious combination for purposes of business, is that of copartnerships, whereby each of the members renders himself answerable, *in solido*, or absolutely, and to the full extent, on all contracts made by the company. This is a sort of association, existing in all places; but if the business to be conducted be of the descriptions above-mentioned, the copartnership is not a convenient mode of association, since the capital contributed by many must necessarily be managed by few; and, therefore, if each member is liable, *in solido*, on the contracts of the company, the fortune of each is put in jeopardy, by ever so small a contribution to the joint-stock. This must operate, of course, to discourage useful undertakings on a large scale, and even if it did not, it might still be very important to provide for associations, with a limited liability of the individual members, since the ruin of any individual will necessarily affect others to a greater or less extent. The shocks, and individual derangements and reverses, which are necessarily incident to enterprises of industry and trade, make it very desirable to secure, by some modes of association, an apportionment of risks, losses, and gains among a great number. This is done by means of private corporations, joint-stock companies, and limited copartnerships. In regard to the two first descriptions of association, it is not always the purpose of their institution to limit the responsibility of the members. In the case of towns, for instance, and so in regard to some other local corporations, an execution, issuing on a judgment recovered against the corporation, may be levied upon the property of any member. So, in some of the United States of America, the individual members of banking or manufacturing corporations are liable absolutely, and without limit, for the debts of the company; but, in general, in both corporations and joint-stock companies, only the capital stock is liable for the contracts of the company. Each member pays in his amount of this stock, which he knows to be subject to the risks of the business to be pursued. He can estimate precisely, therefore, the extent, the utmost limit, of his hazard in the most unfavourable event. With this limitation, many will be ready to embark their capital in enterprises attended with the chances of great gain, or losses, according to the event, who would be quite unwilling to take the hazard of being individually liable for the whole amount of the losses of the whole concern, or of guaranteeing the responsibility of the other members of the company as copartners. In this way, enterprises conducive to the general prosperity are promoted, which individuals would not otherwise engage in. Formerly, when the pursuits of commerce were less systematically conducted, and its risks and its profits more uncertain, commercial joint-stock companies were much more frequent than at present. These companies were favoured by governments, in the first place, as promoting trade; in the second, as the means of raising a revenue. The government granted to a certain company, or to certain persons, the exclusive right to carry on a certain branch of trade or production, for a certain time, or within certain limits. The

company paid the government for this privilege, intending, of course, to indemnify themselves by their profits. They paid a tax with the intention of reimbursing themselves, just as an importer pays duties on his goods, intending to charge the amount, with a profit, in the price to the consumer. It was in opposition to these monopolies that the doctrines of free trade, as they are called, originated; and, considered in reference to such monopolies, these doctrines are undoubtedly just, and so universally held to be; but they are extended by many much beyond these limits. Where only the fund is liable, and not the individuals who contribute it, no injustice is done to the creditors of the company, provided the law secures the actual payment of the fund; for if a person gives credit to a certain fund, knowing the risks to which it is exposed by the kind of business in which it is embarked, he has no ground of dissatisfaction with the members of the company, or the laws, though this fund should prove to be insolvent. This is the most limited responsibility of the contributors to a joint-stock. In other associations of this kind, the contributors are liable to a certain amount for the debts of the concern; as, for instance, to an additional amount equal to that of their respective shares of stock; or each is liable for his proportion of the debts, according to that of his stock. There are also, in the different associations of this description, under the laws of different countries, various conditions on which the liability depends; and also various conditions, which must be complied with, in managing the concerns of the company, in order to keep within the limit of the modified responsibility. Still another description of joint-stock companies is that of limited copartnerships, or companies in which one or more of the members are liable *in solido*, and the others no otherwise liable than for the loss of the proportion of capital which they have put into the concern. This is uniting in the same company the characteristics of a corporation with the most limited responsibility of individual members, and those of a copartnership with an unlimited individual liability. The evident advantages of limited copartnerships, by giving encouragement to persons depending on income, and not devoting themselves personally to the prosecution of active business, to devote their capital to production and trade, without subjecting them to unlimited responsibility, recommend them to adoption in every code of laws. Joint-stock companies, whatever their form, and however extensive or limited the liability of the members, are subject to one abuse, which grows out of their very nature and constitution, and cannot, therefore be wholly prevented. They are liable to be used, by fraudulent or over sanguine people, as bubbles. The fact of their being subject to such perversion, produces a strong and unjust prejudice against them, in the minds of many persons. There is no institution or form of association that is free from abuses and perversions. The engines of greatest power act the most destructively when their powers are wrongly directed, or when they are deranged in their action; but this is no ground of argument against making use of them. It is only a reason for precautions and regulations.

JOINT TENANTS are those that hold lands or tenements by one title, without partition. The creation of an estate in joint tenancy depends on the wording of the deed or devise by which the tenant claims title, and cannot arise by act of law. If any estate be given to a plurality of persons, without adding any restrictive, exclusive, or explanatory words, this makes them immediately joint tenants in fee of the lands. If there be two joint tenants, and one release the other, this passes a fee without

the word *heirs*. Joint tenants may make partition. The one party may compel the other to make partition, which must be by deed; that is to say, all the parties must, by deed, actually convey and assure to each other the several estates which they are to take and enjoy severally and separately. Joint tenants must jointly implead and be jointly impleaded with others. If one joint tenant refuse to join in an action, he may be summoned and severed; but if the person severed die, the writ abates in real actions, but not in personal and mixed actions.

JOLIBA, or DJOLIBA. See *Niger*.

JOLLY BOAT. See *Boat*.

JOMELLI, Niccolò; a musical composer, born 1714, at Aversa, in the kingdom of Naples. He first studied at Naples, under Feo, and afterwards under Martini at Bologna. At first, he composed ballets—a sort of music then so little esteemed in Italy, that he did not own himself the author of his first comic opera (*L'Errore Amorofo*), but gave it to the world under the name of Valentino, a master of not much reputation. This opera, which he composed at the age of twenty-three, probably for the new theatre at Naples, was crowned with great applause, by which he was encouraged to continue his compositions. In 1738, he wrote his *Osiride* for the theatre of Florence, with still greater success, which induced him, in 1740, to go to Rome. He now wrote, from 1740 to 1748, fourteen operas for Rome, of which the *Adriante*, *Ifigenia*, and *Costa Mario*, are particularly worthy of mention, in the latter of which, the beautiful air *Spesso, so rade a morir*, was received with the highest admiration. Besides these, he composed several operas for Venice and other cities. He now received the place of chapel-master in St Peter's, and composed, besides several *moettes*, the psalm *Benedictus Dominus Deus Israel* (Blessed Lord God of Israel), the music of which is a masterpiece. The duke of Wurttemberg then engaged him in his service, and Jomelli went to Stuttgart, where he remained from 1748 to 1763, enjoying the highest distinction, and exercising great influence on German music. When he returned to Italy, John V., king of Portugal, invited him to his court. Although he declined this invitation, he composed a considerable number of operas for the king, and sent him copies of all his subsequent works. He afterwards composed two operas in Rome, both of which were unsuccessful. He then removed to Naples, where he met with no better success; and, August 28, 1774, he died of apoplexy, produced, as is supposed, by chagrin at the success of the German Schuster, and the ill reception of his own opera. His *Requiem* and *Miserere* are particularly celebrated.

JONAH (*Hebrew*, signifying *dove*, and also *the powerful*), one of the minor prophets, son of Amittai, and according to 2 *Kings*, xiv, 25, a contemporary of Jeroboam II., was born at Gath-Hepher, in Galilee. In the book which bears his name, it is related that he received a command from God, to go and prophesy against Nineveh; but he fled to Joppa, and embarked for Tarshish. The vessel being tossed by a storm, it was concluded to draw lots, in order to determine who was the cause of the tempest. The lot fell upon Jonah, who was thrown overboard by his own request, because he had been disobedient to God, but was swallowed by a large fish (according to the ancient commentators, a whale; according to moderns, a shark). After he had remained three days and nights in the belly of the fish, the Lord spake unto the fish, and it vomited out Jonah on dry land. He now went to Nineveh, and prophesied destruction; but, the king and people having repented, Nineveh was spared. Jonah, angry at this, went

out of the city, and God made a gourd grow up over him, which was a shade to him. He then sent a worm, which smote the gourd so that it died in one night. Jonah was angry at this also; but God showed him the foolishness of being angry at the destruction of a gourd, and yet demanding the destruction of a city in which were 120,000 innocent children. Jonah's grave is shown at Mosul, the ancient Nineveh, and also at Gath. Some critics maintain that the book was not written by Jonah himself, but is a collection of traditions, made after the destruction of Nineveh. Some writers consider it merely as an allegorical poem. The story of Jonah is also known to the Mohammedans, according to whom, he embarked after his prophecy at Nineveh, and remained forty days in the belly of the fish. The prayer of the prophet in this situation, is considered one of the most efficacious in the Koran.

JONATHAN, or BROTHER JONATHAN; the nickname given to the Americans of the United States collectively, by the British, probably on account of the frequency of this name among the early Americans. See *John Bull* and *Yankee*.

JONES, INIGO; the reviver of classical architecture in England, in the beginning of the seventeenth century. He was a native of London, where his father was a cloth-worker, and was born about 1572. Destined for a mechanical employment, his talents attracted the notice of the earl of Arundel, and of William, earl of Pembroke, the latter of whom supplied him with the means of visiting Italy, for the purpose of studying landscape painting. He went to Venice, where the works of Palladio inspired him with a taste for the art of architecture, in which he rose to great eminence. His reputation procured him the post of first architect to Christiern IV., king of Denmark, who, visiting his brother-in-law, James I., in 1606, brought Jones with him to England. He was induced to remain, and was appointed architect to the queen, and subsequently to Henry, prince of Wales. After the death of the prince, he again visited Italy, and remained there some years. During this interval, he extended his knowledge, and improved his taste, from the examination of the models of ancient and modern art. The banqueting house at Whitehall (intended as an adjunct to a magnificent palace) is a monument of his skill and science. At Winchester cathedral, a Gothic building, he erected a screen in the style of classic antiquity. Like his successor, Wren, he seems not to have duly appreciated the peculiar character and distinctive beauties of the pointed style of building, of which so many fine specimens remain in the ecclesiastical structures of the middle ages, in Britain, France, and Germany. He built the front of Wilton-house, in Wiltshire, for Philip, earl of Pembroke, and was much employed by the court and by many of the nobility and gentry, so that he realized a handsome fortune. His talents were often put in requisition for the purpose of designing the scenery and decorations for masques—a species of dramatic entertainment, fashionable in the early part of the seventeenth century. In these pieces, the dialogues and songs were composed by Ben Jonson, who quarrelled with Jones, and abused him in epigrams and satires. The enmity the poet was not the only misfortune to which the architect was exposed. Being a Roman Catholic, and a partisan of royalty, he suffered in the civil war, in 1646, was forced to pay a fine of £545, as a traitor and cavalier. The ruin of the royal cause, the death of the king, distressed him greatly; and at length, worn down by sorrow and suffering, died, July 21, 1652. As an author, he is known for a work relative to that curious monument of our ages, Stonehenge, on Salisbury plain, pub-

lished after his death, by his son-in-law, Mr Webb. The object of this treatise, composed by the command of king James I. is to prove that Stonehenge was erected by the Romans, and was a hypæthral temple, dedicated to the god Cælus. A collection of the architectural designs of Inigo Jones was published by Kent, in 1727 and 1744, and others more recently, by Ware and by Leoni.

JONES, SIR WILLIAM, an eminent lawyer and accomplished scholar, was born in London, September 20, 1746. He lost his father when only three years of age, and the care of his education fell on his mother, a lady of uncommon endowments. At the close of his seventh year, he was placed at Harrow, and, in 1764, he entered University college, Oxford. Here his desire to acquire the Oriental languages induced him to support, at his own expense, a native of Aleppo, to instruct him in the pronunciation of the Arabic language; and as it was soon perceived that he would not misspend his time, the college tutors allowed him to follow his own plans unmolested. His great object was to attain a fellowship, to spare his mother the expense of his education; but, not succeeding in his wish, he accepted, in 1765, the office of tutor to lord Althorp, afterwards earl Spencer; and, some time after, he obtained a fellowship also. He availed himself of a residence at the German Spa, with his pupil, in 1767, to acquire the German language; and, on his return, translated into French a Persian life of Nadir Shah, brought over in MS. by the king of Denmark, at the request of the under secretary of the duke of Grafton. Another tour to the continent, with his pupil and family, followed, which occupied his time until 1770, when, his tutorship ceasing, he entered himself as a law student in the Temple. He did not, however, wholly sacrifice literature to his professional pursuits; but, on the appearance of the life and works of Zoroaster, by Anquetil du Perron, he vindicated the university of Oxford, which had been attacked by that writer, in an able pamphlet in the French language, which he wrote with great elegance. He also published, in 1772, a small collection of poems, chiefly from the poets of Asia, and was the same year elected a fellow of the royal society. In 1774 appeared his work *De Poesi Asiatica*, containing commentaries on Asiatic poetry in general, with metrical specimens in Latin and English. He was soon after called to the bar, and, in 1776, made a commissioner of bankrupts. About this time, his correspondence with his pupil evinced the manly spirit of constitutional freedom by which he was actuated; and to his feelings on the American contest he gave vent in a spirited Latin ode to liberty. In 1778 appeared his translation of the Orations of Isæus, with a prefatory discourse, notes, and commentary, which, for elegance of style, and profound critical and historical research, excited much admiration. In the mean time, he rapidly advanced in professional reputation, although his opinion of the American contest stood in the way of his progress to legal honours. The tumults of 1780 induced him to write a pamphlet on the Legal Mode of suppressing Riots; and, in the following winter, he completed a translation from the Arabic of seven poems, of the highest repute. He also wrote the much admired ode, commencing "What constitutes a state?" These pursuits did not prevent a professional Essay on the Law of Bailments. He distinguished himself, in 1782, among the friends to a reform in parliament, and also became a member of the Society for Constitutional Information. The same year, he drew up a Dialogue between a Farmer and a Country Gentleman, on the Principles of Government; for the publication of which, the dean of St Asaph, afterwards his brother-in-law, had a bill of indictment

preferred against him for sedition. Upon this event, he sent a letter to lord Kenyon, then chief-justice of Chester, owning himself the author, and defending his positions. On the accession of the Shelburne administration, through the influence of lord Ashburton, he obtained, what had long been the object of his ambition, the appointment of judge in the supreme court of judicature, Bengal, to which he was nominated in March, 1783, and knighted. He arrived at Calcutta in September, 1783. Here a new field of action opened to him, and he planned a society in that capital, similar to the royal society in London, of which new institution he was chosen the first president. He then applied himself with ardour to the study of the Sanscrit, and, his health soon suffering from the climate, he took a journey through the district of Benares, during which cessation of public duties, he composed a tale in verse called the *Enchanted Fruit*, or the *Hindoo Wife*, and a *Treatise on the Gods of Greece, Italy, and India*. In 1785, a periodical work, entitled the *Asiatic Miscellany*, was begun at Calcutta, to which he communicated several poetical compositions of the minor kind; among which were nine hymns, addressed to as many Hindoo deities. He next employed his active mind in planning the compilation of a complete digest of the Hindoo and Mohammedan laws, with a view to the better administration of justice among the natives. This work he did not live to finish, but its subsequent accomplishment was entirely owing to his recommendation and primary labours. His object in this instance was, to secure a due attention to the rights of the natives; and he showed himself equally jealous of those of the British inhabitants, by opposing an attempt to supersede the trial by jury. The publication of the *Asiatic Researches*, or memoirs of the society to which he had given birth, also engrossed much of his attention; and he enriched them himself with a number of curious and interesting papers. In 1789, he gave to the world the translation of an ancient Indian drama, entitled *Sacountala*, or the *Fatal Ring*. His translation of the Ordinances of Menu, the famous Indian legislator, appeared early in 1794, and is very interesting to the student of ancient manners and opinions. Unhappily, he was seized, in April, 1794, at Calcutta, with an inflammation of the liver, which terminated his life on the 27th of the same month, in the forty-eighth year of his age. Few men have died more respected and regretted than this amiable man and eminent scholar, who, as a linguist, has scarcely ever been surpassed. His acquaintance with the history, philosophy, laws, religion, science, and manners of nations, was most extensive and profound. As a poet, too, he would probably have risen to great eminence, if his ardour to transplant foreign beauties, and his professional and multifarious pursuits, had allowed him to cultivate his own invention with sufficient intensity. His private character was estimable in all the domestic relations, and he was equally liberal and spirited in public life. The memory of Sir William Jones received many testimonies of respect, both in England and India. The directors of the East India company voted him a monument in St Paul's cathedral, and a statue in Bengal; but the most effectual monument of his fame was raised by his widow, who published a splendid edition of his works, in 6 vols. 4to, 1799, and also, at her own expense, placed a fine marble statue of him, executed by Flaxman, in the anti-chamber of University college, Oxford.

JONES, JOHN PAUL, a distinguished commander in the American naval service, was born at Arbigland, Kircudbright, in Scotland, July 6, 1747. His father was a gardener whose name was *John Paul*; but the

son assumed that of *Paul Jones* in subsequent life, for what reason is not known. He early evinced a predilection for the sea, and, at the age of twelve, was bound apprentice to a respectable merchant of Whitehaven, in the American trade. His first voyage was to America, where his elder brother was established as a planter. He was then engaged for some time in the slave-trade, but quitted it in disgust, and returned to Scotland, in 1768, as passenger in a vessel, the captain and mate of which died on the passage. Jones assumed the command, at the request of those on board, and brought the vessel safe into port. For this service, he was appointed by the owners master and supercargo. While in command of this vessel, he punished a sailor who afterwards died of a fever at the island of Tobago—a circumstance which gave rise to an accusation against Jones, of having caused his death, by the severity of the punishment upon him; but this has been completely refuted. Jones was afterwards in command of the *Betsy*, of London, and remained some time in the West Indies, engaged in commercial pursuits and speculations, by which it is said he realised a handsome fortune. In 1772, he was residing in Virginia, arranging the affairs of his brother, who had died intestate and childless, and about this time took the name of *Jones*. In Virginia he continued to live until the commencement of the struggle between the colonies and mother country. He offered his services to the former, and was appointed first of the first lieutenants, and designated to the *Alfred*, on board of which ship, to use his own language in one of his letters, “he had the honour to hoist, with his own hands, the flag of freedom, the first time it was displayed on the Delaware.” Soon after this, we find Jones in command of the *Providence*, mounting twelve four-pounders, with a complement of seventy men, cruising from the Bermuda to the Gut of Canso, and making sixteen prizes in little more than six weeks. In May, 1777, he was ordered to proceed to France, where the American commissioners, Franklin, Deane, and Lee, were directed to invest him with the command of a fine ship, as a reward of his signal services. On his arrival in France, he was immediately summoned to Paris by the commissioners. The object of the summons was to concert a plan of operations for the force preparing to act against the British on the West Indies, and on the coast of America. The plan, which certainly did great honour to the projector, though untoward delays and accidents prevented its immediate success, was afterwards openly claimed by Jones as his own, without acknowledging the assistance, or participation of the American commissioners or the French ministry. The *Ranger* was then placed under his orders, with discretion to cruise where he pleased, with the restriction, however, that he was not to return to France immediately after making attempts upon the coast of Britain, as the French government had as yet declared itself openly as the ally of the United States. April 10, 1778, he sailed on a cruise during which he laid open the weakness of the British coast. With a single ship, he kept the whole coast of Scotland, and part of that of England for some time, in a state of alarm, and made a descent at Whitehaven, where he surprised and took the forts, with thirty pieces of cannon, and sent fire to the shipping. In this attack upon Whitehaven, the house of the earl of Selkirk, in whose service the father of Jones had been gardener, was plundered and the family plate carried off. But the next was committed without his knowledge, and he afterwards made the best atonement in his power. After his return to Brest with 200 prisoners of war, he became

involved in a variety of troubles, for want of means to support them, pay his crew, and refit his ship. After many delays and vexations, Jones sailed from the road of St Croix, August 14, 1779, with a squadron of seven sail, designing to annoy the coasts of England and Scotland. The principal occurrence of this cruise was the capture of the British ship of war *Serapis*, after a bloody and desperate engagement, off Flamborough head, September 23, 1779. The *Serapis* was a vessel much superior in force to Jones' vessel, the *Bon Homme Richard*, which sank not long after the termination of the engagement. The sensation produced by this battle was unexampled, and raised the fame of Jones to its acme. In a letter to him, Franklin says, "For some days after the arrival of your express, scarce any thing was talked of at Paris and Versailles, but your cool conduct and persevering bravery during that terrible conflict. You may believe that the impression on my mind was not less strong than on that of the others. But I do not choose to say, in a letter to yourself, all I think on such an occasion." His reception at Paris, whether he went on the invitation of Franklin, was of the most flattering kind. He was every where dressed; the king presented him with a gold sword, bearing the inscription, *Fiduciatu maris Ludovicus XVI. remuneratur strenuo vindici*, and requested permission of congress to invest him with the military order of merit—an honour never conferred on any one before who had not borne arms under the commission of France. In 1781, Jones sailed for the United States, and arrived in Philadelphia, February 18 of that year, after a variety of escapes and encounters, where he underwent a sort of examination before the board of admiralty, which resulted greatly to his honour. The board gave it as their opinion, "that the conduct of Paul Jones merits particular attention, and some distinguished mark of approbation from congress." Congress passed a resolution, highly complimentary to his "seal, prudence, and intrepidity." General Washington wrote him a letter of congratulation, and he was afterwards voted a gold medal by congress. From Philadelphia he went to Portsmouth, New Hampshire, to superintend the building of a ship of war, and, while there, drew up some admirable observations on the subject of the American navy. By permission of congress, he subsequently went on board the French fleet, where he remained until the conclusion of peace, which put a period to his naval career in the service of the United States. He then went to Paris, as agent for prize-money, and, while there, joined in a plan to establish a fur trade between the north-west coast of America and China, in conjunction with a kindred spirit, the celebrated John Ledyard. In Paris, he continued to be treated with the greatest distinction. He afterwards was invited into the Russian service, with the rank of rear-admiral, where he was disappointed in not receiving the command of the fleet acting against the Turks in the Black sea. He found fault with the conduct of the prince of Nassau, the admiral; became restless and impatient; was intrigued against at court, and calumniated by his enemies; and had permission, from the empress Catharine, to retire from the service with a pension, which was never paid. He returned to Paris, where he gradually sunk into poverty, neglect, and ill health, until his death, which was occasioned by jaundice and dropsy, July 18, 1792. His last public act was heading a deputation of Americans, who appeared before the national assembly to offer their congratulations on the glorious and salutary reform of their government. This was before the flight of the king.

Jones was a man of signal talent and courage; he conducted all his operations with the most daring

boldness, combined with the keenest sagacity in calculating the chances of success and the consequences of defeat. He was, however, of an irritable, impetuous disposition, which rendered him impatient of the authority of his superiors, while he was, at the same time, harsh in the exercise of his own; and he was deficient in that modesty which adorns great qualities and distinguished actions, while it disarms envy and conciliates jealousy. His early education was of a very limited kind. It terminated when he went to sea, at the age of twelve; but he supplied its defects by subsequent study, so as to enable himself to write with fluency, strength, and clearness, and to sustain his part respectably in the polished society into which he was thrown. In his letters, he inculcates the necessity of knowledge for naval officers, and intimates that he had devoted "midnight studies" to the attainment of that information which he deemed requisite in his situation. His memorials, correspondence, &c., are quite voluminous. He also wrote poetry, and, in Paris, was a great pretender to *ton*, as a man of fashion, especially after his victory over the *Serapis*, which, of course, gave him great  *eclat* amongst the ladies of the French capital. At this period, he is described by an English lady then resident at Paris, as "a smart little man of thirty-six; speaks but little French, and appears to be an extraordinary genius, a poet as well as a hero." An account of his life has been written by J. H. Sherburne (Washington, 1828). A memoir of him was also recently published by Messrs Oliver and Boyd, Edinburgh; and Mr Allan Cunningham has made him the subject of a romance.

JONES, JOHN, an American physician, was born at Jamaica, Long Island, in 1729. After receiving his education at a private school in the city of New York, he commenced the study of medicine, under doctor Thomas Cadwalader, and afterwards visited Europe, to improve his professional knowledge. He obtained the degree of doctor of medicine from the university of Rheims, and, having subsequently spent some time at Leyden, concluded his medical tour by a visit to Edinburgh. Returning to America, Doctor Jones settled in New York, where he was speedily introduced to an extensive practice, and acquired particular reputation as an operator. When medical schools were instituted in the college of New York, Doctor Jones was appointed professor of surgery, upon which branch he delivered several courses of lectures, diffusing a taste for it among the students, and explaining improvements as practised in Europe, of which the American faculty were hitherto ignorant. Having for a considerable time been afflicted with asthma, he embarked for London, where he experienced some alleviation of his complaint. He returned to his native country at a crisis when she required the exertions of all her citizens. In the year 1775, he published his *Plain Remarks upon Wounds and Fractures*—a work particularly useful to the country at that period. Many persons had been of necessity chosen to act as surgeons in the continental army, who were ignorant of the recent improvements in the profession, and found in this work a valuable assistant. When the British troops took possession of New York, doctor Jones, notwithstanding the assurances of protection from the royal commander, retired into the country, relinquishing his lucrative practice in the city. He was soon after chosen to a seat in the senate of New York, and subsequently entered the medical department of the army. The hardships of a military life injured his delicate health, and obliged him to abandon the service, for his private practice. Having fixed his permanent residence at Philadelphia, he was elected, in 1780, one of the physicians of the Pennsylvania

hospital. Upon the institution of the college of physicians of Philadelphia, in 1787, doctor Jones was elected vice-president, and contributed to the first volume of its transactions an interesting paper on *Anthrax*. He was the intimate friend and physician of doctor Franklin, whom he attended in his last illness, and published a brief account of his death. In 1790, he attended general Washington, then president of the United States, when very ill at New York. When the seat of the federal government was removed to Philadelphia, the president appointed doctor Jones physician to his family. In June, 1791, he contracted a fever, which, added to his previous disorder, put a period to his life on the 23d of that month, in the sixty-third year of his age.

**JONGLEURS.** See *Jugglers*.

**JONSON, BENJAMIN**, a celebrated English poet, the contemporary and friend of Shakspeare, whom he has been accused by some, but on insufficient grounds, of regarding with envious and malignant feelings. He was the posthumous son of a clergyman, who had suffered considerable privations for his religious opinions, and was born, June 11, 1574, at Westminster; at the grammar-school of which city he was placed, under Camden, at an early age; till his mother marrying again to a person who held the humble occupation of a bricklayer, young Ben, as he was familiarly called, was taken home abruptly by his father-in-law, and employed by him as an assistant in his trade. The ardent spirit of the future poet revolted against his condition; he fled from home, and entered the army as a private soldier, in which capacity he served with much commendation from his officers on the score of personal courage, during a campaign in Holland. Returning to England, he quitted the service, and, although his straitened circumstances threw in his way obstacles of no common magnitude, he determined to apply himself to literary pursuits. With this view, he contrived to enter himself of St John's college, Cambridge; but his failing resources prohibited him from continuing long at the university. He went to London, and commenced at once author and actor by profession—two callings then frequently combined. His progress as a performer was not rapid, and, before he could make any great impression in his favour, a quarrel with a brother actor seemed to close every avenue against this method of gaining a reputation. He had made his *début* at the Curtain, an obscure theatre on the skirts of the town, and, a difference arising between him and another member of the company, a duel ensued, which terminated in the death of his antagonist, while he himself received a wound in the sword-arm. He was seized and imprisoned, and narrowly escaped with life, in consequence of this rencounter. During his confinement, he is reported to have become, through the intervention of a Roman Catholic priest, a convert to that communion, and to have remained so during a space of twelve years, when he resumed his former opinions. His first attempt at dramatic composition, in the prosecution of which he is said to have been much encouraged, if not actually prompted, by Shakspeare, was in 1598, when his *Every Man in his Humour*, still considered a standard piece, was printed; and from this period, he seems to have produced a play annually for several years, besides writing, occasionally, masks and interludes, for the entertainment of the court. The favour he had enjoyed there, was not, however, sufficient to protect him from the consequences of a severe and imprudent satire on the Scottish nation, in a dramatic piece, which he wrote in conjunction with Marston and Chapman, entitled *Eastward Ho*. The anger of the court favourites was at once drawn upon his head by this unfortunate

sally; he was a second time committed to prison, and only a timely submission saved his nose and ears, which he was condemned to lose in the pillory as a libeller. By his address, however, he soon contrived to reinstate himself in the favour of a monarch to whose pleasures the effusions of his muse had become necessary; and for the remainder of that reign he continued in high favour as a kind of superintendent of the court revels, enjoying, at the same time, the friendship of all the wits and literati of the age. After a tour through France, in 1613, in the progress of which, with his usual carelessness, he affronted cardinal Du Perron, he returned to England, and afterwards obtained the honorary degree of A. M. from the university of Oxford. On the death of the poet laureate, Jonson was appointed his successor, and the salary of 100 marks, attached to that post, was, on his petition, raised to the sum of £100 by Charles I. But neither this addition to his income, nor a subsequent gratuity from the same royal master, could save him from the consequences of pecuniary improvidence. An attack of palsy at length carried him off, Aug. 16, 1637. Jonson's best dramas are his *Alchymist*, *Epicene*, and *Volpone*, which, besides being admirable as to plot and development, exhibit traits of pungent humour, strong conception, and powerful discrimination. The remainder of his dramas are inferior. His tragedies of *Sejanus* and *Catiline* are too learned and declamatory either for the closet or the stage, and a great portion of his comedy is low, forced, and unnatural. Contrary to Shakspeare, he deals rather in passing manners and eccentricities than in general nature, but supports a good notion of the follies of his times. His poetry is occasionally illuminated by vigorous and pleasing passages, and a few of his short pieces, poems, and, especially, the Hymn from *Cynthia's Revels*, his epitaph on the countess of Pembroke, and some of his songs and *Underwoods* are excellent. Besides his dramatic and poetical productions, he was the author of a variety of miscellaneous works, among which are an English Grammar, *Discoveries*, &c. Several editions of his works have been published, the last and most complete of which is that by Mr. Gifford. A curious tradition prevailed with respect to the deposition of his remains in Westminster abbey, where a handsome tablet has been erected to his memory, in Poet's corner, inscribed *O rare Ben Jonson!* The same words are found on several square stones in the floor of the abbey, under one of which it was generally believed his corpse was buried in a perpendicular position. This was ascertained a few years since to be the fact, his coffin being discovered so situated in one of the stairs during the preparations making for a recent amendment.

**JOPPA.** See *Jaffa*.

**JORDAN.** This river, celebrated in Scripture history, rises at the foot of the Antilibanus in Syria (in the pachalic of Damascus), forms the lake Timsareth or Tiberias, traverses Palestine, of which it is the only important river, from north to south, receives the Kedron, and, after a course of about 120 miles, empties into the Dead sea. The banks are steep, and about fifteen feet high. Its borders, once cultivated and inhabited, are now deserted, and a yellow water rolls slowly in the sand. The Hebrews called it *Jordan* (river of judgment); the Arabs call it *Nahar-el-Chirra* (river of the ford). They ascribe to bathing in its waters the power of healing.—On the countries near the Jordan and eastward, see J. S. Buckingham's *Travels among the Arab Tribes inhabiting the Countries east of Syria and Palestine* (London, 1825, 4to.).

**JORDAN, DOROTHEA**; an English actress of

eminence in various departments of the drama. Her father, captain Bland, of a respectable Irish family, eloped with her mother, who was a native of Wales, by whom he had a numerous offspring. The subject of this article adopted the theatrical profession, for the support of herself and her mother, and made her first appearance at Dublin, in the character of Phebe, in *As You Like It*; but her talents first attracted particular attention in tragedy. At the theatre of York, she assumed the name of *Mrs Jordan*, by which, though never married, she was subsequently known. In this situation, she continued three years. She made her first appearance before a London audience, as Peggy, in the *Country Girl*; and, in that character, in *Nell*, in the *Devil to Pay*, and others of a similar cast, she displayed unrivalled excellence. She appeared to almost equal advantage as a tragic actress, where tender rather than violent and lofty feelings were to be portrayed. Her long theatrical career was terminated by her retirement to France, where she resided in obscurity, and died (1816) without a relative or friend near her, to soothe the hours of sickness, or bestow on her remains the decent rites of sepulture. She was, for a long time, the mistress of the duke of Clarence, now William IV., who had several children by her. Since his accession, the king has ordered Chantry to prepare a statue, to be placed over her remains, in the cemetery of St Cloud.

JORDANO. See *Giordano*.

JORNANDES (properly *Jordanes*), by birth an Alan, lived under the emperor Justinian, was at first a notary, and afterwards took the monastic vows, but is erroneously styled *bishop of Ravenna*. His *De Guborum Origine et Rebus Gestis*, and his chronicle *De Regnorum et Temporum Successione*, which came down to the year 552, are of much value, though written in barbarous Latin. They are contained in *Muratorii Script. Rerum Italicarum*.

JORTIN, JOHN, D. D., an eminent scholar and divine, was born in London, in 1698, and was educated at Cambridge. Here, under the instruction of Doctor Thirlby, he acquired so high a character for learning and acuteness, that he was recommended by his tutor to Pope, to extract the notes from Eustathius, to print with his translation of the *Iliad*. He took orders in 1724, and he served a chapel of ease to the parish of St Giles in the Fields. In 1731, in conjunction with some learned coadjutors, he gave to the world *Miscellaneous Observations upon Authors, Ancient and Modern* (two volumes, 8vo.); and, in 1731, appeared the first volume of his *Remarks upon Ecclesiastical History*, of which four volumes more were published in 1752 and 1754, and two more after his death in 1773. In 1755, he published *Six Dissertations upon various Subjects*. In 1758, he published his *Life of Erasmus* (4to.); in 1760, another 4to. volume, entitled *Remarks upon the Works of Erasmus*. In 1762, he received the living of Kensington, the duties of which he performed for the remainder of his life. In 1764, he was made archdeacon of London, and died Aug. 20, 1770. Besides the works already mentioned, doctor Jortin was the author of *Remarks upon Spencer* (1734, 8vo.); *Remarks on Seneca*; *Letters on the Music of the Ancients*; and other miscellaneous productions, which appear in two volumes of *Tracts, Philological, Critical and Miscellaneous*. Seven volumes of his *Sermons and Charges* were also published after his death, in 1771 and 1772.

JORULLO, JURULLO, or JURUYO, or XURULLO; a volcano of Mexico, in Mechoacan, thirty miles south Pasquaro, sixty-five south-south-west Valladolid; lon. 103° 52' W.; lat. 19° 9' N. This volcano was formed on St Michael's day, in 1759 in

the middle of a beautiful, fertile, and pleasant valley, which extends three leagues from east to west, and more than eight from north to south. By the skirt of this mountain passes a stream, which before fertilized the valley, and which is called *del Salto*. The waters are so hot that men or horses passing through it are in danger of being scalded.

JOSEPH, Sr; husband of the virgin Mary, the mother of Jesus, a Jew of the tribe of Judah, whose genealogy from Abraham and David is given by St Matthew and St Luke. He is represented in the New Testament as an humble mechanic, and a just man; but little is known, with certainty, of his history.

JOSEPH, the son of the favourite Rachel, was tenderly beloved by his father Jacob. Stung with envy and with the arrogance which they thought was displayed in his innocent dreams, his brothers sold him to some Ishmaelitic slave-dealers, by whom he was sold to Potiphar, a distinguished officer in Egypt. The prudence and fidelity which he displayed in the service of his master ameliorated his condition; but his refusal to comply with the unlawful desires of Potiphar's wife caused him to be thrown into prison, at her instigation. Yet, even here, Joseph was able to gain the confidence of the keeper; and the interpretation which he gave to a dream of the king's butler, who was likewise in prison, opened for him the way to a better fortune; for, after the butler had been restored to favour, Pharaoh and his whole court were troubled by a dream. The butler remembered the Hebrew boy, who had given so happy an interpretation to his own dream when in prison. Joseph was brought to court, and explained the king's dream of seven fat and seven lean kine. The monarch now released him from confinement, and raised him to the second place in the empire. He suggested wise measures for preserving the people from famine, during the unproductive years which he had predicted, and Pharaoh committed to him the charge of carrying them into execution. Married to the daughter of an Egyptian nobleman, in possession of the highest power next to the royal, Joseph saw all his wishes gratified, except his yearning after his relations. In the years of famine, his brothers came to buy corn from the stores which he had collected in Egypt. Without making himself known to them, he endeavoured, by some harsh treatment, to discover their thoughts, and to make them repent of the wrong they had done him. His feelings at length overcame him. He disclosed himself to his brethren, and provided them and his father with lands in Egypt. He was now their benefactor, and therefore Jacob, in his last blessing, gave to his two sons equal rights with the other brothers, and the two tribes of Manasseh and Ephraim preserved the memory of Joseph among the Hebrews.

JOSEPH I., emperor of Germany, son of Leopold I., born at Vienna, July 26, 1678, received the crown of Hungary in 1689, and was soon after crowned as Roman king. In 1705, he began his reign, which, though short, was troubled by wars in the Netherlands, Hungary, Germany, Italy, and Spain. He was well disposed, but weak and indolent. He revived the imperial chamber. The Protestants enjoyed toleration and some privileges under his reign. He died April 17, 1711.

JOSEPH II., German emperor, son of Francis I. and Maria Theresa, was born March 13, 1741, at a time when Frederic the Great had already conquered half of Silesia, and the Bavarian army was approaching the Austrian frontiers, when the peace of Aix-la-Chapelle restored the sinking state. Joseph was inferior to his brother (Leopold II.) in learning, but he displayed an active and penetrating mind, and made much progress,

particularly in the languages, mathematics and music. His lively temperament often brought him into collision with his mother, whom he obeyed from respect, but without conviction, and with secret reluctance. He observed how much her devotional spirit was abused, and he imbibed an invincible aversion to the clergy. She set a great value on birth, and he early acquired a dislike for undeserved privileges. In the mean time, the seven years' war having broken out, every preparation was made for the young prince joining the army, when Maria Theresa recalled her order. In 1760, he married Elizabeth of Parma, who died on her second confinement. He also lost his second wife, a Bavarian princess. He was elected king of the Romans in 1764, and, on the death of his father, 1765, German emperor. His mother declared him co-regent in the hereditary states of the house of Austria, and gave him the command of the army; but the real authority remained in her hands. During the war, Joseph had had cause to admire the great enemy of his house. Animated by this example, he entered on his elevated career; but, as he had but little real power, excepting in military affairs, in which, with the aid of Lascy, he introduced some improvements, he employed his time in travelling, and becoming acquainted with his states. On one of these journeys, under the title of *count Falkenstein*, he visited Frederic the Great in his camp at Neisse, August 25, 1768. The two monarchs, dispensing with ceremonies, met on terms of familiarity, like friends. In the following year, the emperor, in his camp, received a visit from Frederic. In 1777, Joseph made a journey to Paris, where he spent six weeks. Every body was charmed with him. At the end of this year, the elector of Bavaria died, and the war of the Bavarian succession broke out between Prussia and Austria, to which Maria Theresa put an end, without the knowledge, and contrary to the wishes of her son, who was desirous of measuring himself in the field with his great adversary. In 1780, Joseph came into the possession of full dominion over his hereditary states, at the age of forty years, and was thus the sovereign of more than twenty-two millions of men, with a fine army. His people adored him; the nobility and clergy alone had reason to fear him. Joseph had drawn on himself their hatred, by ordinances, which were, in many respects, very excellent. He allowed a greater freedom of the press, put an end to the connexion between Rome and the religious orders, diminished the pensions, placed the Jews on a better footing, abolished bondage, suppressed all nunneries and many monasteries, particularly those in which there were no schools, or the sick were not taken care of, or the monks did not preach. In the spring of 1782, pope Pius VI. made a visit to Vienna. Joseph afterwards returned his visit at Rome, still continuing to suppress monasteries, so that in eight years, the number belonging to the different orders had sunk from 63,000 to 27,000. All branches of the government, public education, the police, the state of the clergy, and the peasantry, were reformed. By a new code of laws, capital punishments were abolished. His attempts at reform in Hungary, which he wished to render uniform with his German states, caused a rebellion of the *Walachians*, which he could quell only by the execution of its leaders, *Horia* and *Gloska*. Then followed, 1784, the dispute with Holland, concerning the free navigation of the *Scheldt*, and the negotiations for the exchange of the Netherlands for Bavaria, against which the confederacy of the German princes was formed, in 1785. In 1797, under the title of *count Falkenstein*, Joseph made a journey into the Crimea, where Catharine gave him a most splendid reception

at Cherson. After his return, he experienced a series of misfortunes. Disturbances having broken out in the Netherlands, Joseph discontinued his reforms, and quiet seemed to be restored. February 9, 1788, he declared war against the Turks. By the defeat at *Lugos* (September 20, 1788), the army was obliged to retreat, and suffered dreadfully in consequence of the heat and the unhealthiness of the country. Joseph himself, exhausted and charmed by the misfortune of his army, returned sick to Vienna in December. In the following year, fortune favoured the Austrian arms; *Belgrade* was recovered to *Laudohn*, and the Russians made great progress. The principal cause of the difficulties which Joseph next had to encounter, was the tax law, introduced in November, 1789. The nobility and peasantry showed themselves equally dissatisfied, and the signal was given for general disorder and open rebellion. The Netherlands declared themselves independent, and expelled the imperial forces from all the provinces, and *Luxemburg* only remained in the possession of the imperial troops. Joseph showed himself ready to make concessions; but all his proposals were scornfully rejected. The Hungarians, also, whose general dissatisfaction had been only slumbering, rebelled, and demanded the restoration of their ancient rights and constitution. To the astonishment of all Europe, Joseph, in January, 1790, declared all the acts of his government in that country revoked, even to the edict of toleration (June 17, 1781). Tyrul showed signs of dissatisfaction, and Joseph hastened to put every thing on its former footing. His health sunk under these accumulated mortifications, and the consequences soon became apparent. February, 1790, he was sensible that death was rapidly approaching, and, on the 20th, he died of a pulmonary consumption.—Joseph was of the middle size; of a lively disposition, sickly, and fond of action, of ruling, of destroying and building up. Courage in danger was a striking trait in his character. He had a strong and lively sense of the dignity of man, and respected it in all. He caused the *Augarten*, hitherto closed, to be made public, and placed over the entrance the inscription, "Dedicated to all men, by one who values them." When requested to permit only certain classes to walk in the *Prater*, in order that they might enjoy themselves there with their equals only, he refused, and added, "If I would live only with my equals, I must go to the tomb of the emperors, at the *capuchin* chapel, and there spend my days." To *Schmidt*, the historian of Germany, he said, "Spare no one, not even myself, if you come down so far with your history. Posterity must judge of my faults, and those of my predecessors." Frederic the Great wrote to Voltaire concerning him—"Joseph is an emperor such as Germany has not had for a long time. Educated in splendour, his habits are simple; grown up amidst flattery, he is still modest; inflamed with a love of glory, he yet sacrifices his ambition to his duty." Joseph's favourite object was to be sovereign in a peculiar sense, and to manage the great machine of the state entirely himself. Whatever his own relations, or his knowledge of other countries, showed to be useful, he wished to introduce. But he did not sufficiently consider that he had to do with other men, with other relations, and that long habit rendered it difficult to change, at once, usages sanctified by time; that other men did not possess his knowledge and experience. (See *Anecdotes of the Emperor Joseph II.*, and *Paul's Characteristick*, Vienna, 1790). Dohm's Memoirs also contain important information on Joseph's system of government and reform. The Letters of Joseph II. (Leipzig, second edition, 1822) are valuable.

JOSEPHINE (*Rose Tascher de la Pagerie*), empress of the French, queen of Italy, was born in Martinique, June 24, 1763. While very young, her father took her to France, to marry her to the viscount Beauharnais (q. v.),—a marriage arranged by the two families, when the marquis Beauharnais was governor-general of the Antilles. Madame De Beauharnais, in the prime of her beauty, and still more adorned by that peculiar grace which distinguished her throughout her life, had what was then called great success at court. She bore the viscount two children, Eugène (q. v.) and Hortense; but neither the brilliant life of the court, nor her love for her children, had been able to lessen her filial attachment to her mother, to attend whom, in her sickness, she went to Martinique, in 1787. She took her daughter with her, and passed three years in the island. The troubles which then broke out very suddenly, obliged her to flee without taking leave of her mother, and to return to France, where she arrived after narrowly escaping great perils. A singular prophecy had been made to her when a child, which she used to mention when it was apparently fulfilled in her high destiny. She is said frequently to have indulged in this play of divination. Her husband was known, in the beginning of the revolution, as an advocate of constitutional principles, and his standing, as well as the benevolence of his wife, naturally made their house a kind of asylum for the unfortunate. Mlle. De Béthisy, condemned by the revolutionary tribunal, owed her life to the courageous intercession of Mad. De Beauharnais. But the fury of terrorism increased, and her husband, who had valiantly defended France at the head of its armies, was thrown into prison, and executed. She was also included in the list of proscription; but the death of her husband reduced her to such a state that she could not be removed, and to this circumstance she owed her escape from execution. Robespierre at length perished, and the viscountess was delivered from prison by Tallien, who was never forgotten by her, nor by Eugène, from whom he received a considerable pension till his death. Joséphine was indebted to Barras for the restoration of a part of the property of her husband, and at his house, after the 13th Vendémiaire, she met general Bonaparte, who had previously taken an interest in her for the following reason: The disarming of the citizens having been decreed, a boy of fifteen years presented himself to Bonaparte, and with great earnestness demanded the sword of his father. The boy was Eugene; and Bonaparte, touched by his filial zeal, was desirous to become acquainted with his mother, to whom he immediately became attached. He married her in 1796, and never ceased to have the greatest esteem for her. She followed the hero of Italy, and her whole life was now intimately connected with that of Napoleon, at whose side she stood, like a good genius. She had considerable influence over him, and his letters to her are proofs of her amiable character, and of his warm attachment to her. She was always benevolent, and accessible to any who sought protection or mercy from Napoleon through her. The comparison which Napoleon drew, at St Helena, between the two empresses, as recorded in Las Cases' Memorial, is honourable to both. Bourrienne tells us, that some shameful calumnies rendered general Bonaparte jealous while in Egypt, but that, soon after his return, every thing was adjusted. Joséphine used her influence in favour of many emigrants, encouraged arts and industry, and protected the humblest artists whom she found worthy. "If I," said Napoleon, "win battles, you win hearts;" and it certainly seems as if Napoleon could not have found a woman

who united all the qualities of heart and mind, which would fit her for the companion of his career, in a greater degree than Joséphine. Polignac and Riviere owed their lives to her. Her court was no less admired in France than she herself was beloved. She loved pomp. When Napoleon ascended the throne, a divorce was proposed, but the emperor rejected the proposition. Joséphine was crowned at Paris and at Milan. When Napoleon became desirous of marrying a princess, she felt it deeply, yet she had firmness enough to consent to what he thought best for France and for himself. She retired to her beautiful seat of Malmaison, with the title *imperatrice-reine-douairière* (empress-queen-dowager), where the respect and the love of all the French followed her, who was called *l'étoile de Napoleon*. She was doomed to see the destruction of that throne on which she had once sat. The emperor Alexander and the king of Prussia, but particularly the former, showed their respect for her virtues by repeated visits to Malmaison; but the fate of Napoleon undermined her strength, and, having exposed herself while in a feeble state of health, by walking with Alexander, she took a cold, and died in the arms of her children, May 29, 1814. Her last words were *L'île d'Elbe!—Napoleon!* Her body was deposited in the church of Rueil, and was followed by a numerous procession, in which the emperor Alexander was represented by general Sacken. Seven years afterwards, her children received permission to erect a monument to her, who had so long been called the guardian angel of France. Joséphine was handsome; her figure was elegant and majestic; but her greatest charms were her grace and goodness of heart. The *Mémoires Historiques et Secrets de l'Impératrice Joséphine* (2 vols., published in November, 1820, by the famous Parisian sibyl, Mlle. Le Normand) contain many interesting, though unauthenticated anecdotes, respecting the life of this remarkable woman.

JOSEPHUS, FLAVIUS, born thirty-seven years after Christ, at Jerusalem, of the order of the priesthood, was an ornament to the sect of the Pharisees, to which he belonged, and for a long while governed Galilee. He afterwards obtained the command of the Jewish army, and supported with courage, with wisdom, and resolution, a siege of seven weeks, in the fortified town of Jotapha, where he was attacked by Vespasian and Titus. The town was betrayed to the enemy: 40,000 of the inhabitants were cut to pieces, and 1200 were made prisoners. Josephus was discovered in a cave, where he had concealed himself, and was given up to the Roman general, who was about to send him to Nero, when, as it is related, he predicted that Vespasian would one day enjoy the imperial dignity, and thereupon had the good fortune to obtain both freedom and favour. This induced him, when he went with Titus to Jerusalem, to advise his countrymen to submission. After the conquest of Jerusalem, he went with Titus to Rome, and wrote the history of the Jewish war, of which he had been an eye-witness, in seven books, both in the Hebrew and Greek languages—a work which resembles the writings of Livy more than any other history. His Jewish antiquities (in twenty books) is likewise an excellent work. It contains the history of the Jews, from the earliest times till near the end of the reign of Nero; but it is censured, as giving an incorrect account of the miracles of Christ, and as suppressing or altering every thing which might have given offence to the heathen. As a wise politician, he made the predictions of a Messiah refer to Vespasian. His two books on the Antiquity of the Jewish People contain valuable extracts from old historians, and are aimed at Apion, an Alexandrian grammarian, and an open adversary of the Jews. The best edition

of his works is that of Haverkamp (Amsterdam, 1729, in two volumes, folio, Greek and Latin.) The last edition is by Oberthur (Leipsic, 1781—85).

JOSQUIN DE PREZ, ADRIAN, JOSQUINUS, or JODOCUS DE PRATO; one of the greatest musical masters of the Netherlands, who received the surname *Prato* from his residence during several years at Prato in Tuscany. He was a pupil of John Okenheim, called the *Sebastian Buch* of his time. After having studied with Okenheim, Josquin went to Italy, received an appointment, in 1475, in the papal chapel, and acquired so much reputation by his *motettes*, masses, and other church compositions, that he was invited to Cambrai, made chapel-master to Louis XII., and Francis I., and then to the German emperor Maximilian I. He died at Brussels, where his tomb is shown in the church of St. Gudala. He was justly admired as a contrapuntist, a hundred years before Palestrina and Orlando. "Josquin," said Luther, after having heard one of his masses, "is master of the notes: they must do as he chooses; other composers must do as the notes choose." The celebrated Senfel and Nicolas Gombert were his pupils. See Burney's *History of Music*, or the article *Josquin*, in Rees's *Cyclopædia*.

JOUIJOU (*French*, which, if literally translated, would be *play-play*); a plaything, consisting of two thin circular plates of wood, about two inches in diameter, united in the centre by a cylinder one-sixth of an inch long. Fixed to the cylinder is a cord about a yard long or more, which is fastened with a noose to the finger. If the cord is wound round the cylinder, and the *joujou* is let fall, you can, by a pull before the whole cord is wound off, make the *joujou* wind itself up entirely. In this the whole play consists, and yet, from 1790 to 1794, the *joujou* was so fashionable in France, that the highest persons were seen playing with it on their walks, and in society. The fashion also extended to Germany.

JOURNAL. Every one has found, with surprise, how quickly impressions, even of important events, vanish; how quickly we confound dates and forget names. "It is singular," says Byron, "how soon we lose the impression of what ceases to be constantly before us: a year impairs: a lustre obliterates. There is little distinct left without an effort of memory," &c. For him, then, who wishes to live beyond the passing moment, and retain vividly the memory of his past life, it is of great importance to keep a journal. The practice, indeed, is somewhat in disrepute, owing to the frivolous details of some journals, and the sentimental folly of others. Experience leads us to advise the keeping of a brief journal, to retain the vestiges of the passing time. A date, a name, a jest, a grave observation, interspersed now and then with a whole day's proceeding, given in as condensed a form as possible, a slight drawing, &c., may afford valuable reminiscences. A simple rule is to put every thing in your journal which you expect will be interesting to you after a series of years. Young persons especially should avoid loading their journals with sentiment. In addition to the pleasure which we derive from a faithful picture of our former lives, it is very useful for a hundred purposes, to have the means of finding exact dates, descriptions, and names.

*Journal*, in navigation; a sort of diary or daily register of the ship's course and distance, the winds and weather, together with a general account of whatever is material to be remarked in the period of a sea voyage, such as the shifting, reducing, or enlarging the quantity of sail, the condition of the ship and her crew, the discovery of other ships or fleets, lands, shoals, breakers, soundings, &c.

*Journal* is also the name given to newspapers and

some other publications which appear at regular intervals. See *Newspapers* and *Periodicals*.

JOURNEYMAN, formed from the French *journeur* (a day's work), anciently signified a person who wrought with another by the day; but it is now used to designate any mechanic who works for another in his employment, whether by the month, year, or any other term. It is applied only to mechanics in their own occupations.

JOVELLANOS, GASPARD MELCHIOR DE, one of the most distinguished Spaniards of modern times, was born in Gijon, in Asturia, Jan. 5, 1744, of an ancient and noble family, and studied at Oviedo, Avila, and Alcala de Henares. As soon as he left college, according to the custom of the country, to raise lawyers of noble birth immediately to the bench. Jovellanos was made *alcalde del crimen*, or a member of the criminal branch of the *audiencia* in *Seville*. Count Aranda, then president of the council, becoming acquainted with him, seems to have marked him out for one of his new school of administrators, in his attempts to improve the state of the country.\* He advanced rapidly in his professional career, in the complicated system of the Spanish judiciary, and was finally appointed to the quiet and dignified station of member of the council of the military orders at Madrid. Here he became a useful member of various learned societies, particularly of the *Real Sociedad economica Matritense de Amigos del Pais*—an institution intended for the promotion of agriculture, manufactures, and trade. In the meetings of this society, he read his *Elogios* of the celebrated architect don Ventura Rodriguez, and of king Charles III., and it was by the command of the same body that he wrote his celebrated *Informe sobre las Propuestas de Ley Agraria*, to which he mainly owes his fame. It is not true that he was prosecuted for the free principles expressed in this work. Jovellanos formed an intimate friendship with a brilliant French adventurer, Cabarrus, which proved fatal to him; for the latter became entangled in a prosecution, instituted by count Lerma, minister of finances, which led to his disgrace at court, and he was banished to his native place. Here he remained from 1790 to 1797, entirely devoted to his various studies and useful projects, including, among other things, the working of coal mines. He also founded the royal Asturian institution—his darling project up to the last moments of his life.

Meanwhile don Manuel Godoy, afterwards Prince of Peace, had risen, or rather leaped, from the barracks to the station of prime minister. Godoy was an ignorant man, who happened to adopt the idea of being a "philosophical minister." Cabarrus became his favourite, and Jovellanos was again invited to office, which he accepted with great reluctance. On his arrival at Madrid, he dined with Godoy and his mistress; and we learn from one of his letters how repugnant this and the whole affair were to his stern virtue. Still, the thought that he might do some good in the wretched state of the public administration, kept him in public life. Jovellanos was made minister, and a colleague of Francisco de Saavedra, with whom he soon formed a close friendship. They were both sensible of the miserable character of the government of Godoy, and prevailed on the king to dismiss him. Saavedra was appointed, in his place, minister of foreign affairs. But this administration was soon dissolved, and both lost their places. Jovellanos was not so much regretted as might have been expected from his noble character, for he was not a

\* Jovellanos was the first judge in Spain who had the courage to abandon the wig; and it required all the support of the prime minister, count Aranda, to counterbalance this step.

very practical head of a department. The revenge of the Prince of Peace was slow, but deep. Marquis Caballero, than whom a baser instrument could hardly be found, even in that court, and in those times, was chosen to persecute him. A Spanish translation of Rousseau's *Contrat Social*, in one of the notes of which Jovellanos was mentioned favourably, gave the pretext. He was arrested, carried from one place to another, and, at last, put in a Carthusian monastery in the island of Majorca. His addresses to the king from this place are bold and vigorous, and were read by the whole nation, because the hatred against the Prince of Peace was then at its height. Intestine commotions and foreign power at last put an end to the wretched government. Charles IV. was compelled to abdicate in favour of his son Ferdinand, with whom Caballero, betraying his friends, had sided, so that the mob, who had forced Charles IV. to abdicate, shouted, *Viva el pícaro Caballero!* (the knave Caballero for ever!) Jovellanos was now recalled by the same person who had shamefully persecuted him. He demanded a trial; but Napoleon's stroke at Bayonne changed the face of Spanish affairs. Joseph, his brother, anxiously engaged all men in his administration, who stood high in the esteem of the people, and offered Jovellanos the portfolio of the interior, advised to do so by Urquijo, D'Azanza, Massaredo, O'Farill, and Cabarrus, the intimate friends of Jovellanos, who said they had a positive assurance of his willingness to accept it. If this was actually the case, either the loss sustained by Joseph's party at Baylen, or the insurrection of the Spaniards soon after this event, made him change his mind. Jovellanos, on the other hand, assures us that his friends urged him to accept the ministry, but that he never thought of doing so, thus forming one of the few well informed and liberal men who did not join Joseph. Jovellanos embraced the cause of the insurgents, and became a member of the central junta, where it was chiefly owing to him, that the council—precisely the same in Spain as the parliaments in France, in *esprit-de-corps*, aristocratic feeling, sale of offices, &c.—was revived. No sooner had the council met, than it opposed the central junta, which was finally dissolved, and Jovellanos was shamefully treated. To expose the council, and defend himself and the junta, was the last of his labours as a writer. He died November 27, 1811, sixty-seven years old.

The cortes, though Jovellanos objected to the principle upon which they were founded, declared him *benemérito de la patria*, a distinction afterwards often bestowed injudiciously. His Spanish prose is considered the finest of modern times. His *Elogios*, though possessed of some faults inherent in all compositions of that kind, are redeemed by great beauty of language and depth of thought. He also wrote an Essay upon Dramatic Exhibitions and Public Diversions, some poems, and a tragedy, *El Pelayo* (the brave Goth who defended the independence of Spain against the Moors), which was prevented by the clergy from being played before 1790, and a translation of the first book of Milton; but his poetry will not procure immortality for his name. The *Pan y Toros* (Bread and Bulls), an essay against bull-fights, has been generally ascribed to him, but without reason. In an excellent address at the distribution of prizes in the academy (of fine arts) de St Fernando, in 1781, he depicted the course of the fine arts to his time, from which Cumberland derived his opinions on Spanish artists. According to Jovellanos, Lope de Vega and Jordanes were the promoters of bad taste, the former in poetry and the latter in painting.

See *Memorias para la Vida del Excmo. Don Gaspar Melchior de Jovellanos*, y *Noticias analíticas de*

*sus obras por Don Juan Agustin Cean Bermudez* (Madrid, 1814), extracts of which are given in the Letters from Spain, by Leucadio Doblado (Blanco White), London; and *Noticias Historicas de Don G. M. Jovellanos, consagradas a sus respetables Cenizas. I. M. de A. M.* (Palma, 1812, 4to.) The wretched state of the Spanish book-trade does not allow a complete collection of his works to appear.

JOVIUS, PAUL (or *Paolo Giovio*), a celebrated Italian historian, was born at Como, in 1483, studied medicine at Pavia, but took orders, and was bishop of Nocera at the time of his death, in 1552. In his youth he read the classics under the direction of his brother at Rome, and was inspired with the desire of becoming the historian of his time. His first attempt was read by pope Leo, to an assembly of cardinals, and the pontiff exclaimed, that—"after Titus Livy—there is no writer more elegant and eloquent."—Tiraboschi shows that he has often been represented as a liar and flatterer, and two letters of Jovius himself appear to furnish ground for objections against him. He there asserts that an author has the privilege of dressing some in soft silk, and others in linen; and that he would not write without being paid. "*So in otio, quia nemo nos conduxit.*" Ranke, in his valuable work *Zur Kritik neuerer Geschichtschreiber* (Berlin, 1824), justly observes that a letter may be written in a moment of ill humour, but his works must be examined to determine whether he actually praised his friends and patrons immoderately. He openly censures the popes, his masters, in expressions which Catholics would blame in a Protestant writer; and we ought not to forget the passages in which he speaks of the fidelity due from a historian. As to the money which he wanted for his writings, it is easily explained. In his time, authors received no remuneration from publishers, but from princes or other eminent individuals. But we have no reason to suppose that this affected his statements. Ranke observes, that he has not found any misrepresentation of facts, in order to please, in Jovius's works, as far as he had accurately examined them, which was down to the year 1530. As Jovius lived at the court of the pope, then still, to a certain degree, the capital of Christendom, he became personally acquainted with many individuals of the first importance in history, or other eye-witnesses, from whom he gathered information. His style is not unfrequently too florid or diffuse, and his statements may, perhaps, be coloured by his partialities. His Latin is very excellent, but the deep views of a Machiavelli are wanting. His works are, *Historia sui Temporis* (1494—1547), lib. xlv. (2 vols., Florence, 1548—1552, fol.); *Elogia Virorum erudit.* (Florence, 1549, fol.); *Elogia Virorum bellica Virtute illustrium* (ib. 1551, fol.); *Comment. de Rebus Turcicis* (Wittenberg, 1537); *Descriptio Britanniae, Scotiae, Hiberniae, et Orcadum* (Bale, 1578, fol.)

JOYEUSE ENTREE; the name given to the important privileges of the estates of Brabant and Limburg, with Antwerp, which the dukes were obliged to swear to maintain, before they were allowed to enter the ducal residence, from which circumstance the name was taken. The most important of these privileges was, that the people were released from all allegiance, whenever the duke should attempt to violate their rights. So important were these privileges considered, that many women went to Brabant to be confined there, that their children might enjoy the rights of a citizen of Brabant.

JUAN (pronounced *huan*, with a very aspirated *h*). Juan is the Spanish name for John, and a character named *Don Juan* is found in the literature of most of the modern nations of Europe. As far as we know, this character first appears in the *Burlador de Sevilla y Convidado de Pierra*, a comedy by Gabriel

Telles, commonly called *Tirso de Molina*. It is well known that the early French dramatical poetry was much influenced by the Spanish, and the *Convivado de Pierra* was reproduced by Molière, as *Don Juan, ou Le Festin de Pierre*, a comedy in five acts, after the Spanish piece had already met with great success in an Italian dress in Italy. This name has derived its greatest fame, however, from the opera of Mozart, called *Don Juan*, one of his most brilliant compositions. The variety of sentiments, which the grand composer was able to express in this opera, gave to his vast genius an opportunity to treat, almost in the same breath, the most ludicrous and the most sublime subjects. Don Juan is justly one of the most popular compositions of the German opera. In all these works, don Juan is a travelling rake, who practises every where the arts of seduction. He is equally successful in the higher and the lower ranks, and having invited the marble statue of a commander to sup with him, is horrified by seeing the statue actually descend from his marble steed to accept the offer. Don Juan is finally consumed by flames from the infernal regions. The *Don Juan* of lord Byron bears no relation to the old story, but in name, and the libertine character of the hero.

JUBA, a king of Numidia and Mauritania, favoured the cause of Pompey against Julius Cæsar, and, after the battle of Pharsalia, joined his forces to those of Scipio. He was conquered in a battle at Thapsus, and totally abandoned by his subjects. He killed himself, with Petreius, who had shared his good fortune and his adversity, A. U. C. 707. His kingdom became a Roman province, of which Sallust was the first governor.

JUBA II., a son of Juba I., was led among the captives to Rome, to adorn the triumph of Cæsar. In his captivity, he applied himself to study. He gained the hearts of the Romans by the courteousness of his manners, and Augustus rewarded his fidelity by giving him in marriage Cleopatra, the daughter of Antony, conferring upon him the title of king, and making him master of all the territories which his father once possessed, A. U. C. 723. The Mauritians rewarded his benevolence by making him one of their gods. The Athenians erected a statue in his honour, and the Ethiopians worshipped him as a deity. Juba wrote a history of Rome in Greek, which is often quoted and commended by the ancients. Only a few fragments of it remain. He also wrote on the history of Arabia, and the antiquities of Assyria, chiefly collected from Berosus. Besides these, he composed some treatises upon the drama, Roman antiquities, the nature of animals, painting, grammar, &c., now lost.

JUBILATE; the third Sunday after Easter. In the primitive church, divine service was begun with the words of the 65th Psalm, 1st verse—*Jubilate Deo, omnes terre*, Sing to the Lord, all ye lands.

JUBILEE; one of the extraordinary festivals of the Jews, which was held at the end of every fiftieth year. This festival was proclaimed by the sound of trumpets through the whole country, on the evening of the day of atonement, about the autumnal equinox. It was distinguished by many eminent privileges. All debts were to be cancelled. All slaves or captives were to be released. All estates which had been sold reverted to their original proprietors or their descendants. Houses in walled towns, however, were exempted from this provision. During this year the ground was not cultivated. The political object of it was to prevent great oppression of the poor, as well as their liability to perpetual slavery. The distinction of tribes, too, was thus preserved, in respect both to their families and their possessions; for the law rendered it necessary for them to keep

genealogies of their families, in order that they might be enabled to prove their right to the inheritance of their ancestors. The jubilee, too, probably assisted in the computation of time, like the Greek Olympiads, the Roman lustra, and the Christian centuries.

In imitation of the Jewish jubilee (or, as some later writers have endeavoured to prove, of the secular games of the Romans), the Roman Catholic church instituted a year of jubilee, during which the pope granted plenary indulgences to all who, having confessed and partaken of the Lord's supper, shall visit certain churches. The first proclamation for a jubilee was issued in 1299, by Boniface VIII. The profit which the Roman chair drew from it, and the wish that more Christians might have an opportunity of partaking in it, induced Clement VI., in 1350, to declare every fiftieth year, then Urban VI., in 1389, every thirty-third year, and Paul II., in 1470, every twenty-fifth year, a year of jubilee. The quantity of money which the jubilee brought to Rome, induced Paul to designate certain churches, in the distant countries of Christendom, where votaries, who could not come to Rome, might obtain the advantages of the jubilee; but on condition that the largest part of the profits of these provincial jubilees should flow into the treasury of the holy see. The money collected by means of these general indulgences was sometimes spent in wars against the Turks, and sometimes used to advance the building of the church of St. Peter's, which, ever since the sixteenth century, had been the standing pretext under which they were issued. The reformation, to which the sale of indulgences gave the first impulse, sensibly diminished these profits, and the jubilee which Benedict XIV. proclaimed in 1750 had but little success, as was also the case with the last, in 1825, proclaimed by Leo XII. Gulielmus Ventura Atensis, who, prompted by the motives of religion, visited Rome during the jubilee in 1800, gives an account, in Latin, of the huge throng which flocked to the holy city, and the abundant harvest which the pope reaped. The following is a translation of a few sentences of his account: "Going out of Rome on the eve of the nativity of Christ, I saw a great crowd, which no man could number. It was noised among the Romans, that there were 2,000,000 of both sexes in the assembled multitude. Repeatedly I saw men and women trampled under foot in the press, and I myself was several times in danger of the same fate. The pope received from them a vast amount of money: for day and night, two priests stood at the altar of St. Peter, holding rakes in their hands, with which they raked in countless sums (*tenentes in eorum sinibus rastellos, rastellantes pecuniam infusam*). The ferocious trampling of this countless throng brought to mind some of the ceremonials of Hindoo worship. The rakes, with which the money was gathered into the pontifical bank, have, in later days, been adapted as the furniture of a hazard, or *rouge et noir* table in gaming-houses.

JUDA, the tribe and kingdom. See *Hebrews*, and *Jews*.

JUDÆA. See *Palestina*.

JUDAS; surnamed *Iscaariot*, from the place of his birth; one of the twelve apostles of Jesus, whom he betrayed into the hands of the Jewish priests, under the semblance of a friendly salutation. His divine Master addressed to him the mild reproof,—Do you betray the Son of man with a kiss? Remove for his crime bid him to suicide. The Cainites, Corinthians, and some other heretics, held him in great veneration.

Judas, brother of James, according to Luke, one of the twelve disciples. Matthew and Mark call him *Thaddæus* surnamed *Lebbæus*. He is considered the author of the epistle which our translators call

the *Epistle of St Jude*, though the name in the Greek is the same in both instances.

JUDAS MACCABÆUS. See *Jews*.

JUDAS' TREE, (*cercis Canadensis*), a small tree, remarkable for the beauty of its rose-coloured flowers, which, appearing in a profusion before the development of the leaves, render it, on a distant view, very similar in appearance to a peach tree in blossom. The structure of the flowers, however, is widely different, and places it in the natural family *leguminosæ*. The leaves are large, simple and cordate. It is found only in the more southern parts of Europe and America.

JUDGES, in Hebrew history. See *Hebrews*.

JUDICA; the fifth Sunday after Lent; so called because the primitive church began the service on that day with the words *Judica me, Domine* (*Ps. xliii. 1.*).

JUDITH; widow of Manasses; a Jewish heroine of great beauty, virtue and courage, whose history is given in the book which bears her name, the author and age of which are unknown. The Catholic church admits it into the canon, but it has been generally considered apocryphal by Protestants. Judith, it is well known, is represented as going out to the tent of Holofernes, an Assyrian general, who was besieging Bethulia, charming him with her beauty, and taking advantage of the admission to his tent, thus afforded her, to cut off his head, while he slept, with his own sword. Some writers have given an allegorical interpretation to this history.

JUGERUM; a Roman measure; a piece of ground which could be ploughed in one day by a yoke of oxen; a Roman acre, 240 feet long, 120 feet broad (28,800 sq. feet). It was the unit of field-measure, and divided into  $\frac{1}{4}$  *jugerum* (*actus quadratus*) = 14,400 Roman square feet;  $\frac{1}{2}$  *jugerum* (*clima*) = 3600. *Actus minimus* was a strip four feet wide and 120 feet long = 480 Roman square feet. Two *jugera* were called *heredium*; 100 *heredia* made one *centuria*, and four *centurie* (= 800 *jugera*) one *salsus*. In the time of the kings, two *jugera* were reckoned a sufficient allowance for a father of a family; at a later period, seven; 376 B. C., fifty; but, even at a still later period, it was considered dishonourable for a senator to possess more than 500 *jugera*.

JUGGERNAUT, or JAGANATH (i. e. *the lord of the world*); the most celebrated and sacred temple in Hindostan, in the district of Cuttack, on the coast of Orissa. The temple stands near the shore, not far from the Chilka lake, in a waste, sandy tract, and appears like a shapeless mass of stone. The idol is a carved block of wood, with a hideous face, painted black, and a distended, blood-red mouth. It is magnificently dressed, and the appellation of *Juggernaut* is one of the names of Vishnu, the preserver of the world. (See *Indian Mythology*.) On festival days, the throne of the image is placed on a tower sixty feet high, moving on wheels, accompanied with two other idols—his white brother, Balaram, and his yellow sister, Shubadra—who likewise sit on their separate thrones. Six long ropes are attached to the tower, by which the people draw it along. The priests and their attendants stand round the throne on the tower, and occasionally turn to the worshippers, with indecent songs and gestures. The walls of the temple and the sides of the car are also covered with obscene images, in large, durable sculpture. While the tower moves along, numbers of the devout worshippers throw themselves on the ground, in order to be crushed by the wheels, and the multitude shout in approbation of the act, as a pleasing sacrifice to the idol. In the temple, a number of prostitutes are kept for the pilgrims who come there, and also several consecrated bulls, which are commonly fed by the

pilgrims with herbs. A bone of Crishna is preserved in the temple as a precious relic, but shown only to a few. Every year, particularly at two great festivals, in March and July, the pilgrims flock in crowds to the temple. It is calculated that there are at least 1,200,000 of them annually, of whom it is said nine out of ten die on the road, of famine, hardship, and sickness; at any rate, it is a well known fact that the country, for miles round the sacred place, is covered with human bones. Many old persons undertake the pilgrimage that they may die on the holy ground. Not far from the temple is a place called *Golgotha* by the Europeans, where the corpses are thrown, and dogs and vultures are always feeding on the carrion. The contributions of the pilgrims amount to a considerable revenue (about £12,000 per annum), which falls to the government, after deducting the expenses of the temple. The English took possession of the province in 1803, and forbore to exact the contribution of the pilgrims, during the marquis of Wellesley's administration; but on his departure from India, the Bengal government passed an ordinance for the management of the pagoda, and the taxing of the pilgrims. The superintendence of the temple and priests was given, in 1809, to the rajah of Kurdah, with the charge of executing the old regulations. A road from Calcutta to the temple has been made since 1810, to which a wealthy Hindoo, rajah Sukmoy Roy, contributed £16,000 sterling, on condition of its being called by his name.

JUGGLERS; men who perform, in public, tricks of legerdemain. In the middle ages, the name of *jongleurs* was given to the instrument-players who accompanied the Troubadours. Afterwards these performers employed themselves in tricks and games, which, if Ducange's derivation of *jongleur* from *jocularis*, or *joculator*, is correct, must have been their original occupation. They accompanied with dramatic action the songs which they helped to sing; they were buffoons, and united in bands, which had many privileges. They formed in Paris a society, the members of which dwelt together in the *Rue des Jongleurs*, afterwards *St Julien des Ménestriers*. Those whom we now call jugglers, men of wonderful activity, and skilful equilibrists, were then distinguished by the name of *bateleurs*, or *batalores*. From the accounts of travellers, we know that in Hither and Farther Asia, between the old Ganges and the Orontes, where the limbs are very pliant, the arts of balancing, of tumbling, and of moving the body rapidly, and with perfect regularity, are still preserved, and have been handed down for thousands of years. Fanatical penances, and the excitement of religious orgies, in those countries where the body is capable of the most unnatural contortions, first gave rise to these tricks of jugglery, which were thought to assist in atoning for the past, or in predicting and determining the future. Thus originated there the juggling tricks, which are likewise met with among several tribes of North America. Raised to an art by the Hindoos, a people addicted to meditation, and fond of games, these tricks became a profession, which is still exercised in its highest perfection in China, on the coasts of Coromandel, and in both peninsulas, on this side, and beyond the Ganges. During the last few years, the people of Europe have been able to verify the accounts of the agility, the muscular strength, and the suppleness in the limbs of these Hindoos, by the sight of jugglers, who, from time to time, have exhibited in Britain, and the continent.

Bottiger has proved that, in ancient times, there were still more wonderful exhibitions of this kind. That which appears to be the most extraordinary trick of these jugglers—the swallowing the sword, and the catching several knives thrown quickly into

the air—was often performed before the ancients; and an inscription in Gruter (*Theat.* p. dcxxxvii, p. 1.) even states that, in the baths of Agrippa, of Titus, and of Trajan, at Rome, a bear was exhibited, dressed in a long toga, who played the same tricks with balls, that surprise us in these Indian jugglers. To such extraordinary occupations did the patience of the *mansuetarii* constrain even beasts, in order to amuse the Roman people, always greedy of what was new and strange, or the luxurious populace of the great provincial cities. Games in which balls, painted with various bright colours, were thrown round the body without interruption, exercises in equilibrium, where every false step was instant death, were exhibited by these birds of passage, the wandering children of every city, in a perfection which yet astonishes us in the accounts and descriptions of the fathers of the church. For the fathers, with Manetho (*Apotelesmat.* iv. 289), and the Latin poet Manilius, whose astronomical poem draws the horoscope for different stations of life, furnish the most satisfactory idea of this part of ancient art. Those who threw the knives the ancients called *ventilatores*, and those who threw the balls in a perpetual circle are mentioned by Quintilian under the name of *pilarii*.

One of the Hindoos, who lately exhibited in Europe, was wonderful for his power of moving every part of his body, without one part preventing the motion of another. While he held in equilibrium, on his forehead, a little building, consisting of pieces of sticks, which would fall apart if not very nicely balanced, and continually put it together and took it to pieces, with his toes he kept in rapid motion a number of rings, which alone would seem to require great skill and attention. A very difficult feat, which he also performed, was to string pearls upon a thread by means of the tongue. This feat, too, the fathers mention expressly, so that the most wonderful tricks now exhibited, were performed before the ancients, that is, before the inhabitants of the large cities of the Roman empire, such as Antioch.

Some have endeavoured to derive from the name of the old lynx sorcerers (*γυναικίς*) the modern word *juggler*, which came last from the Provincial *Langue-d'Oc*. The two arts, which are still united in India, that of divination and of exhibitions of bodily address and agility, were both practised by those ancient artists.

JUGURTHA; the son of Manastabal, a son of Masinissa by a concubine. Under the care of Micipsa, his father's brother, and king of Numidia after Masinissa, he received as good an education as the two sons of Micipsa, Adherbal, and Hiempsal. He was of a fine person, of manly strength, and endowed by nature with superior talents. He early formed himself for a soldier. Micipsa, who began to fear him, determined on his removal, and sent him with an army to assist the Romans against Numantia; but here his valour and conduct won the esteem of the army, and the friendship of Scipio. Micipsa now sought to conciliate him by favours. He adopted him, and declared him joint heir to the crown with his two sons. On his deathbed, he exhorted him to friendship and fidelity towards his two sons, united with him almost by the bonds of brotherhood; and he commanded them to honour Jugurtha, and to emulate his virtues. Jugurtha promised every thing to the dying king, although he had already resolved to become sole master of Numidia. Soon after the death of Micipsa, he caused Hiempsal to be murdered, and drove Adherbal from the country, taking possession of his whole portion of Numidia. Hearing that Adherbal had gone to Rome, he also sent ambassadors there, to counteract by bribes the effect of his representations. The greater part of the senate

declared in his favour. Ten commissioners were named to divide Numidia between Adherbal and Jugurtha, and to make an investigation on the spot, with regard to the murder of Hiempsal. These also were bribed. They declared the murder an act of self-defence, and allotted to Jugurtha the richest provinces. The commissioners had hardly departed, when, to draw Adherbal into a war, he made an attack upon his territory, and committed the most terrible devastations. All this was borne without complaint. Jugurtha now made another attack upon Adherbal, and obliged him to take up arms in self-defence. Adherbal was defeated, and his army destroyed, near the capital city of Cirta. He fled within the walls, and was immediately besieged. He found an opportunity, however, to make known his unhappy situation at Rome; but Jugurtha's friends, by their intrigues, prevented any thing being done except the sending of commissioners. As might have been expected, their mission was of no avail. In the mean while, the siege of Cirta was pressed with vigour. Adherbal was forced to surrender, and, in spite of his promise to grant him life, Jugurtha caused him to be inhumanly murdered. The Roman people now called for more vigorous measures against such a perjured villain, and the senate declared war. The chief command was given to the consul Lucius Calpurnius Piso, a man who united military talents with the most shameful avarice. At first he carried on the war with zeal, and conquered several cities; but he soon after entered into a negotiation with Jugurtha, and granted him, as he had not been sparing of his money, very favourable conditions. He was to retain Numidia, and was merely to give to the republic a certain number of horses and elephants, and a moderate sum of money. Much discontent was shown at Rome, and Jugurtha was obliged to come with a safeconduct, to stand before the tribunal of the people. In Rome, he succeeded in gaining one of the tribunes, so that, when about to answer before the people, the tribune imposed silence upon him, and the assembly dispersed without deciding any thing. Jugurtha now carried his insolence so far in Rome as to cause the assassination of Massiva, an illegitimate son of Gulusa, brother of Micipsa, to whom the Roman people were inclined to award the crown of Numidia. As a safeconduct had been promised him, he merely received orders to quit the city immediately. War was again declared against him, and carried on by the consul Posthumus Albinus; but the artifices of Jugurtha caused the year to pass without any decisive measures being taken. The prince was also fortunate enough, immediately after the departure of the consul, to defeat his brother, Aulus Posthumus, and constrained him to make a shameful peace, and to suffer his army to pass under the yoke; on which account the senate refused to ratify the peace, and sent the celebrated Metellus to Numidia. This general conquered Jugurtha in a great battle, and remained firm against all his bribes. When on the point of signing a shameful peace, and surrendering to the Romans, Jugurtha, through fear that they might inflict vengeance on him for his former crimes, suddenly changed his resolution, and determined once more to abide the worst. He summoned together all his remaining power, and began operations with so much skill, that Metellus saw that his wish of ending the war would not be fulfilled. Marius, at the same time, had, by his intrigues, caused the recall of Metellus, and his own appointment in his place; but, before he left Rome, Jugurtha had narrowly escaped falling into the hands of the Romans by the treachery of one of his servants, Bomilcar. Again beaten by Metellus, he resolved to ask for the assistance of the Getulians, and of

Bocchus, king of Mauritania. He obtained it, and, at the head of a new army, attempted to reconquer his kingdom. In the mean while, Marius had arrived in Africa to supersede Metellus. After taking the city of Capsa, and the fortress of Mulucha, he retired towards the sea coast, but, on his way, was attacked by the joint army of Jugurtha and Bocchus, and obliged to retreat to a neighbouring mountain. Here the enemy surrounded them, and, in the expectation of complete victory, gave themselves up to immoderate joy; but, when fatigued with dancing and feasting, they yielded to sleep, the Romans rushed down upon them from the heights, and completely routed them. Four days after, Jugurtha and Bocchus made a new attack, hoping to surprise the Romans; but Marius received them so valiantly, that nearly their whole army of 90,000 men was cut to pieces, though Jugurtha himself fought with extraordinary bravery. The king of Mauritania now concluded a peace with the Romans, and abandoned his ally. Sylla persuaded him to draw Jugurtha into his power, and deliver him to the Romans. Under pretence of mediating between the contending parties, Bocchus enticed him to his court. He was here seized and delivered to Sylla, who sent him, in chains, to Marius, at Cirta. Thus the war was ended, and Numidia became a Roman province. Marius adorned his triumph with his prisoner Jugurtha and his two sons. After this prince had suffered many insults from the people on this occasion, he was thrown into a dark prison, where he was starved to death after six days. Some historians relate that he was executed in prison immediately after the triumph. His two sons remained captive at Venusium. Sallust has written an account of this war in a masterly style.

JULIA, the only daughter of Augustus and Scribonia, possessed pleasing manners, extraordinary beauty, and a cultivated mind. She was first married to the young Marcellus, the son of Octavia by her first husband. Having soon become a widow, she married Marcus Vipsanius Agrippa, to whom she bore three sons and two daughters. Even during the lifetime of her husband, she led an unprincipled life. All in Rome, except Augustus, were acquainted with her licentious conduct. After the death of Agrippa, he gave her in marriage to Tiberius, who well knew her character, but did not dare to oppose the will of the emperor. After this new marriage, Julia by no means gave up her former indulgences, so that Tiberius, unwilling to be a witness of them, or to complain to Augustus, left the court. Her shamelessness went so far that she caused to be placed on the statue of Mars, every morning, as many crowns as she had had lovers in the past night. Her excesses at last could no longer be concealed from her father. In the most violent anger, he determined at first to have her executed, but afterwards consented to banish her to Pandataria, a desolate island on the coast of Campania, where her mother, Scribonia, accompanied her. He would never forgive her, notwithstanding the earnest supplication of the people. At last, however, he was prevailed upon to permit her to leave the island for the city of Rhegium, on the continent. She never intended to return to Rome. After the death of the emperor, she suffered still more. As long as he had reigned, Tiberius had always professed much tenderness for her, and had often begged him to pardon her; but now he treated her with the greatest cruelty. Therefore, she could not leave the city of Rhegium: Tiberius now confined her to her house. He even took from her the little pension which Augustus had owed her; and she died in the fifteenth year of her exile, in poverty and distress.

JULIAN. Flavius Claudius Julianus, a Roman emperor, to whom the Christians gave the surname of the *Apostate*, son of Julius Constans (brother of Constantine the Great) and of Basilias, his second wife, daughter of the prefect Julian, was born at Constantinople, in the year 331. When hardly six years old, he saw his father and several members of his family murdered by the soldiers of the emperor Constans II., his cousin (a son of Constantine the Great). He and his younger brother Gallus narrowly escaped death. The education of the two princes was intrusted to Eusebius of Nicomedia, who gave them Mardonius for their instructor. They were brought up in the Christian religion, which was yet a new one at the court of the emperor. They were obliged also to enter the order of priests, that they might thus be removed from the throne, and they were chosen readers in their church. This education produced a very different effect on the minds of the two brothers, whose characters were very dissimilar. Gallus, the younger, never left Christianity, and thus obtained the praise of the ecclesiastical historians. Julian, being older, had felt more deeply the persecution of his family, and the constraint and fear in which he was obliged to pass his youth. He therefore sought consolation in the study of philosophy and belles-lettres. At the age of twenty-four, he went to Athens and to Nicomedia, where he enjoyed the society of several instructors, particularly that of the sophist Libanius. Here he was induced to reject the religion of those who had massacred his family, and to embrace paganism. Yet he does not appear to have had sufficient strength of mind to rise above the religious prejudices of that age. At least we find that he believed in astrology, in the science of the *haruspices*, in the art of calling up intermediate spirits to one's assistance, and learning from them the future, with several other superstitious notions. Constans, who feared an attack of the Germans upon the provinces of the Roman empire, determined at last, at the solicitation of his wife Eusebia, to give to Julian the command of an army against them. He was proclaimed Cæsar by Constans, at Milan, in 355, whose sister Helen he received in marriage. He now proceeded, with a small body of troops, to Gaul, which was laid waste by the Germans. It was hardly to be expected that a youth, who thus far had attended only to the study of philosophy and belles-lettres, would be able, especially with so small means, to conquer the formidable enemy against whom he was sent. The emperor Constans himself appears not to have calculated upon the probability of such an event. After Julian had passed the winter in preparations for the ensuing war, he marched against the Germans, took several cities, conquered them in various engagements, and, in a great battle near Strasburg, completely defeated seven of their princes, and entirely delivered Gaul. He pursued the Germans beyond the Rhine, and conquered them in their own country. As a governor also, he displayed extraordinary talents. He gave to Gaul a new constitution. He settled the finances, diminished the taxes, and assessed them more justly, put an end to the abuses which had crept into the courts of justice, administered justice himself in the most important cases, and laid the foundation of cities and castles. While he was thus providing for the happiness of a great nation, he was accused, before Constans, of aiming at independence. The jealousy of the suspicious emperor could not fail to be excited by the brilliant career of his young kinsman in Gaul. He was even base enough to stir up, secretly, the Gauls against him, and to recall his best troops, under pretence that he wanted to employ

them against the Persians. This order caused a rebellion among the soldiers, who were unwilling to go to Persia. They proclaimed their leader Julian emperor, in March, 360, in spite of his own resistance. Julian gave information of the state of things to Constans, who ordered him to renounce his title of emperor. Much as he was inclined to do this, the Gallic legions equally opposed his inclination. The emperor now sent an army against Julian, who made preparations in his defence. He left Gaul, where he had passed five years, took Sirmium, the capital of Illyria, and besieged Aquileia. Here he heard of the death of the emperor Constans. He now passed rapidly through Thrace, and reached Constantinople, December 11, 361, where he was immediately proclaimed emperor. He began by putting a stop to many abuses, and limiting the splendour of his court. Of the thousand barbers, and attendants at the baths, employed by his predecessors, he retained but a single one. The number of cooks, too, which was likewise very great, he reduced to one. The eunuchs were dismissed, as well as those called *curiosi*, who, under pretence of informing the emperor of useful things, were dangerous spies, and the bane of all social intercourse. After these retrenchments, he was able to remit to the people the fifth part of all their taxes. Julian sought to restore the heathen worship in all its splendour, and, on that account, opposed Christianity as much as was in his power, without, however, like many of his predecessors, cruelly persecuting the Christians themselves. He took from the Christian churches their riches, which were often very great, and divided them among his soldiers. He sought likewise to induce the Christians, by flattery or favour, to embrace paganism, and, failing in the attempt, he laboured to make their condition disagreeable. Thus, for example, he forbade them to plead before a court of justice, or to receive offices in the state. Indeed, the Christians were no longer allowed to profess their faith openly; for he well knew what powerful arms the Scriptures afforded for combating paganism. To render false the prophecy of Jesus, with regard to the temple at Jerusalem, he permitted the Jews to rebuild it, about 300 years after its destruction; but it is said that flames of fire arose from beneath, and consumed some of the workmen. In the meanwhile, he wished to end the war with the Persians. His first campaign against them was successful. He took several cities, and advanced as far as Ctesiphon. Want of means of subsistence obliged him to retreat. June 26, 365, he was mortally wounded, and died the following night, in the thirty-fourth year of his age.

There is hardly, either in ancient or in modern history, a prince whom historians have judged so differently. Perhaps it is because his character was full of contradictions; and some believe that he had so many good and so many bad qualities, that it is easy to blame or to praise him without violating the truth. On the one side, learned, magnanimous, moderate, temperate, circumspect, just, merciful, humane; on the other, inconsistent, fickle, eccentric, fanatical, and superstitious in the highest degree, ambitious, and full of eagerness to be at once a Plato, a Marcus Aurelius, and an Alexander, he sought chiefly for the means of distinguishing himself from all others. At the bottom of all these features in his character, there appears to lie a sarcastic, sophisticated coldness and dissimulation. Some of his works have come down to us. Several speeches, letters, and satires, among which the satires on the Cæsars, and that on the people of Antioch, called *Misopogon*, are distinguished for wit and humour. The first is particularly esteemed. A critical judgment passed upon those who had sat upon the first of the thrones of

earth, by a philosopher who had himself occupied the same seat, must indeed possess a peculiar charm. In his *Misopogon*, Julian severely lashes the Antiochians, but spares no praise when he speaks of himself. The best and most complete edition of his remaining works is that of Eskeel Spanheim (Leipzig, 1694, folio). They prove that this emperor possessed talent, wit, vivacity, ease in writing, and some fertility; but he appears to have conformed too much to the taste of his age, in which a mere rhetorical style of declamation took the place of eloquence, antithesis the place of thought, and play on words the place of wit. He wrote also a work against the Christian religion, of which we have yet some extracts that have been translated into French by the marquis D'Argens.

JULIAN CALENDAR. See *Calendar*, and *Epoch*.

JULIANA; a female who possessed great influence at the court of the Mogul emperors of Hindustan in the earlier part of the last century. She was born in Bengal, in 1658, and was the daughter of a Portuguese named Augustin Dias D'Acosta. After having suffered shipwreck, she went to the court of the great Mogul Aurengzebe, whose favour she conciliated by presenting him with some curiosities which she had preserved. Being appointed superintendent of the harem of that prince, and governess of his son Behadur Shah, she had an opportunity of rendering some important services to the latter, who succeeded to the crown in 1707, under the title of *Shah Aulum*. He was under the necessity of defending his newly-acquired authority against his brothers by force of arms; and, in a battle which took place, *Jahann*, mounted on an elephant by the side of the emperor, animated him by her advice when his troops began to give way; and to her exhortations he was indebted for the complete victory which he obtained. Her services were rewarded with the title of princess, the rank of the wife of an omrah, and a profusion of riches and honours. Shah Aulum had such an opinion of her talents, that he was accustomed to say, "If Juliana were a man, I would make him my vizier." Jehander Shah, who became emperor of Hindoostan in 1712, was equally sensible of her merit; and, though she experienced some persecution when that prince was deposed by his nephew, in 1713, she speedily recovered her influence, and retained it till her death, in 1733.

JULIERS; formerly a duchy in Westphalia, bounded north by Gueltern, east by Cologne and the Rhine, south by Blankenheim and Schlesien, and west by Liege, Guelders, and the Meuse. It now forms a part of the Prussian province of the Lower Rhine, and government of Aix-la-Chapelle. It has a fruitful soil, which produces all sorts of cereals in abundance, together with good meadow and pasture land. Much wood also is cultivated here, and iron manufactured.

JULIERS-CLEVES-BERG; a province in Prussia, in the German circles of Lower Rhine and Westphalia, comprehending the late archbishopric of Cologne, the duchies of Cleves and Berg, &c. Population, 908,185; square miles, 3636. It is divided into three governments—Cologne, Düsseldorf, and Cleves. It is one of the most populous territories belonging to Prussia. The Rhine passes through the whole length of it. The inhabitants are Catholics, Lutherans, and Calvinists.

JULIUS; the name of three popes, of whom we shall only mention the two last.

*Julius II.* (Giuliano della Rovere), a native of Albisola, originally a fisherman, was elevated, by his uncle Sixtus IV., to the rank of a bishop and cardinal, was appointed papal legate to France, and, in

1583, was elected pope; and although, while cardinal, the friend of the French, he now became their enemy. He excommunicated the duke of Ferrara, gave Navarre to Spain, besieged Mirandola, commanded his army in person, formed the league of Cambray against Venice, and was altogether warlike in his measures. The king of France and the emperor convened a council at Pisa, before whom he was summoned to appear and explain his conduct; but he did not obey the summons, and called another council in the Lateran. In 1512, he made open war against Louis XII. The French defeated the papal army near Ravenna, but were soon after driven out of Italy. Julius died in 1514. He is considered one of the most immoral of the popes. His conduct certainly was little befitting the head of the Christian church. To procure means for building St Peter's, he ordered the sale of indulgences, which was one of the immediate causes of the reformation, so that the Protestants may say, without paradox, that St Peter's is the great monument of Protestantism. Connected with the plan of rebuilding St Peter's by Bramante was that of embellishing the Vatican; and, on Bramante's recommendation, Julius II. invited Raphael to Rome, in 1508, where he painted a superb suite of apartments, called *La Segnatura*. In the ducal gallery, at Florence, there is a fine portrait of Julius II. by Raphael. See *Bramante*, and *Raphael*.

**Julius III.** (Giovanni Maria Giocchi), a Roman of low birth, called himself *Del Monte*, because his family originated from Monte Sabino, in the Florentine territory. He was made cardinal by Paul III., in 1536, took an active part in the council of Trent, as papal legate, and was the chief cause that it was transferred to Bologna, against the will of Charles V. Julius was elected pope in 1550. He received the fugitive Nestorian patriarch Suluca, and endeavoured to effect a union with the Nestorians. He died 1555, and is accused of the greatest licentiousness, even of unnatural intercourse with a certain innocent whom he created cardinal.

**JULIUS CÆSAR.** See *Cæsar*.

**JULIUS OF MEDICI.** See *Clement*.

**JULIUS ROMANUS.** See *Giulio Romano*.

**JULY**; the seventh month in our calendar, which, in the Roman year, bore the name of *Quintilis*, as the fifth in the computation of Romulus, even after Numa had prefixed January and February. Mark Antony effected a change in its name, in honour of Julius Cæsar, who was born iv. *Idus Quintilis*, and thenceforward, by a decree of the senate, it was called *Julius*.

**JUMNA, or YUMNA**; a celebrated river of Hindoostan, which has its source in the Himalaya mountains. It enters the province of Delhi, and, passing the cities of Delhi and Agra, falls into the Ganges at Allahabad. Its length is estimated at 780 miles.

**JUMPING MOUSE** (*meriones*, F. Cuv.). A little animal which bears a great resemblance, in the length of its hind legs, and mode of leaping, to the jerboa. It is found in America, from Canada to Maryland, and perhaps still farther south. It is about the size of the common mouse. The head, back, and upper parts of the body, are reddish-brown, darkest on the back. The under parts are cream coloured, with a yellow streak passing along the body. The tail is longer than the body. This animal frequents grain and grass fields: it breeds very fast, and occasionally commits considerable havoc. When the cold weather commences, it goes into winter quarters, and remains torpid till the warm season returns. The jumping mouse does not exclusively move on its hind feet, but is capable of running on all-fours with great speed. The leaps taken by this diminutive

creature, when pursued, are astonishing. It sometimes clears five or six feet at a single bound. There is another species found in the vicinity of Hudson's bay, which closely resembles the above, in its habits and mode of progression.

**JUNE**; the sixth month in our calendar. Vossius gives three etymologies of the name—one from *juno*; another from *jungo* (to join), referring to the union between the Romans and Sabines, under Romulus and Titus Tatius; a third from *juniores* (the young men), Romulus having been said to have assigned the month of May to the elders, and that of June to the young men, when he divided the people into these two great classes, the former to serve in counsel, the latter in war. These origins are more fully explained by Ovid. The name has also been traced to Junius Brutus, the first consul.

**JUNG, JOHN HENRY**, called *Stilling*, was born 1740, in Nassau, and died in 1817, at Carlsruhe. In his youth he was apprentice to a tailor. The desire of knowledge which always occupied him, made him afterwards attempt to become a schoolmaster. He was unsuccessful, and returned to the tailors' business, from which, however, he was called several times to become a tutor. At last he succeeded in procuring the means of studying medicine in Strasburg, and was afterwards a physician in Elberfeld. He has described, himself, the greater part of his life; and the celebrated work *Heinrich Stilling's Jugend. Junglingjahre und Wanderschaft* (Berlin, 1777, 3 vols.), in a new form, under the title *Lebensbeschreibung* (Berlin, 1806, 5 vols.), is incomparable. He relates, with modesty and simplicity, the way in which his life was passed among the classes of people less favoured by exterior gifts of fortune; and his pious and pure heart discloses itself so unaffectedly and involuntarily, and the style is at the same time so excellent, that the work is one of the most popular among the German classics. It has a charm of a very peculiar kind, and many readers will sympathize with the author, even in those passages of mystical devotion, which do not accord with the tone of their own minds. His works of devout mysticism are very numerous. Those best known are his *Theobald der Schwärmer, Das Heimweh, Der Volkslehrer*, &c. Much opposition was excited by his strange work *Theorie der Geisterkunde* (Nuremberg, 1808), and the Apology for the same (1809), which is connected with his *Scenen aus dem Geisterreiche* (Frankfort, 1803). In these works, he not only shows his full belief in apparitions, and adduces numerous cases, which he considers undeniable, but also tries, in the first, to establish a theory of the nature of spirits, and the mode in which they appear. Even those who disbelieve entirely in apparitions, will find these works of great interest, because they will show him with how much appearance of truth many of the most remarkable cases are related by several witnesses of respectable character, who had not previously believed in the reality of such appearances, and under circumstances which in ordinary cases, would be considered conclusive. Jung made himself known, also, by his numerous works on medical subjects, the veterinary art, political economy, &c. He was, moreover, one of the most successful operators for the cure of the cataract. "Already has he," says Mathison, in his *Letters* (Zurich, 1795), "restored sight to more than 2000 poor blind people, not only gratis, but in many cases, with the addition of pecuniary assistance." Goethe, in his *Aus Meinem Leben* second volume, pages 378 and 489, gives a fine character of Jung.

**JUNGER, JOHN FREDERIC**, born 1759, at Leipsic, was first apprentice to a merchant, afterwards studied law, and, at a later period, devoted himself entirely

to belles-lettres. He became tutor to two princes and, in 1789, was appointed poet of the court theatre at Vienna; but, in 1794, was obliged to maintain himself solely by his writings. He was extremely diligent, yet his gains were very little: this and his lonely life rendered him subject to fits of deep melancholy, in which, as has been the case with other writers, he produced his gayest works. These were comedies. He wrote a great deal, and died 1797. His comedies have been published in three collections—*Lustspiele* (in five volumes, Leipsic, 1785—1790), *Komisches Theater* (Leipsic, 1792—1795, three volumes), and *Theatralischer Nachlass* Ratisbon, 1803—1804).

**JUNGFRAU** (German, meaning *virgin*): a high mountain, in the canton of Berne, Switzerland, the highest peak of which—the Jungfrau—*horn*—is 13,720 feet high, and was first ascended in 1811. The Jungfrau is one of the most magnificent mountains of Switzerland, and is covered with enormous masses of snow and glaciers. See *Alps*.

**JUNIN, BATTLE OF.** This engagement took place, Aug. 6, 1824, on the elevated plains of Junin, near the lake of Reyes in Peru, when the royalists, under Canterac, were beaten by Bolivar and the united Peruvian and Colombian forces. The combatants fought hand to hand, with lance and sabre, those engaged being cavalry only. This affair was but a prelude to the decisive battle of Ayacucho, which soon followed, and accomplished the final overthrow of the royalist party.

**JUNIPER**; a genus of plants having imbricated, scale-like leaves, closely allied to the cedar and pine, but differing in having the scales of the cone united, and forming a little berry. The *juniperus Virginiana*, commonly called *red cedar*, is frequent throughout the United States of America, from near lat. 45° to the point of Florida, and westward as far as the Rocky mountains. It does not attain large dimensions, ordinarily not exceeding thirty feet in height, but is highly esteemed for the durability and lightness of the wood, which is employed in the upper part of the frames of vessels, for posts, &c., and is also an article of export to Britain. So little regard has been paid to the preservation of this tree, and such has been the demand for the timber, that it is now not easily obtained, and is becoming scarcer every day. As is the case with other forest-trees, the farther south and the more barren the soil in which it grows, the better is the quality of the wood. The cedar apples, frequently used in the United States as a vermifuge, are excrescences formed by insects on the branches of this tree. The red cedar, in many places, appears as the pioneer of the American forest, fixing upon dry and exposed situations, and fostering beneath its shade young trees of various species, till it is finally overtopped by them, and in its turn disappears. The *J. prostrata*, distinguished from the common European juniper (*J. communis*) by its larger and oblong berries, is a trailing shrub, covering often a considerable extent of ground, and inhabiting Canada, and those parts of the United States north of lat. 42°. The *J. barbadensis* inhabits Florida, and other species are found on the Rocky mountains. The wood of the *J. Bermudiana* is exported from the Bermudas, and, among other uses, is employed in the manufacture of black lead pencils. The berries of the *juniperus communis* are made use of to impart their peculiar flavour to spirit, constituting *gin*. They are also used by brewers, to give pungency to the lighter kinds of beer. In some parts of Europe, they are roasted, ground, and used as a substitute for coffee. They are also used in Sweden and in Germany as a conserve, and as a culinary spice, and especially to give flavour to sour-cront.

Like all plants of the terebinthinate class, they have a decidedly diuretic property, and they are much used as diuretic medicines. The oil of juniper, if mixed with nut-oil, forms an excellent varnish for pictures, wood-work, and iron, which it preserves from rust. From the bark exudes a resinous gum, known by the name of *gum sandarach*. It is a small, yellow pieces, very brittle and inflammable, and of a pungent, aromatic taste. When finely powdered and sifted, it constitutes the substance so well known under the name of *pounce*. It is also used by painters in the preparation of varnish, especially of the kind termed *vernix*.

**JUNIUS.** The Letters of Junius first appeared in Woodfall's Public Advertiser, from which they were copied into most of the other journals of the time. The earliest under this signature bears date Jan. 21, 1769; the last, Jan. 21, 1772. After they were completed, they were collected, the collection including also those signed *Philo Junius*, with the letters of Sir William Draper, and those of Horne to Junius, and published by Woodfall, with a dedication to the English nation, and a preface by the author. Besides the letters signed *Junius*, others by the same author were published in the same paper, under the signatures of *Poplicola*, *Adrian*, *Lucius*, *Brutus*, *Nemesis*, *Veteran*, &c., relating to different subjects, but all marked with the same boldness, severity, and passion, which characterized the former. These appeared between April 25, 1767, and May 12, 1772, and are given in the *postscript* Woodfall's edition as the *Miscellaneous Letters*.

Although more than sixty years have elapsed since the publication of these extraordinary papers, we have as yet no positive proofs to decide the question who was the author. The most prying curiosity, and the most industrious ingenuity, have been at work to collect circumstantial evidence on this point, and volumes have been written about it; but if we may believe a statement which appeared in the *London Globe* some years ago, the author is a person who had not then been named in all the controversies respecting these letters. "Five letters, deposited in the archives of the Grenville family, at *Stowe*, establish beyond a doubt," says the *Globe*, "the real author of Junius. That individual was particularly connected with Geo. Grenville, from whom these autograph proofs have descended to their present possessor. The venerable statesman (lord Grenville, son of G. Grenville), nearly allied to the duke of Buckingham (grandson of G. Grenville), has requested the discovery should not be published during his life." It will be seen that one of the recent writers on this disputed subject has suspected the author to have been lord Temple, the brother and political friend of Geo. Grenville. Baile (Reminiscences, first series, letter on Junius), speaking of the copy which the author ordered of his publisher "bound in vellum," also says, "Who is the possessor of this copy? The reminiscence thinks it was not unknown to the founder of a noble house, in which the public owes an edition of *Hume's* which does the nation honour" (referring, doubtless, to the edition of Oxford, 1800, *impensis D.D. Buckingham et Grenville*).

A writer in the *Edinburgh Review* (vol. 43, article *On the Author of Eikon Basilike*) says, "A simple test ascertains the political connexions of Junius: he supported the cause of authority against America with Mr Grenville, and maintained the highest popular principles on the Middlesex election with the same statesman: no other party but the Grenvilles combined these two opinions." Junius, we may add, was also in favour of triennial parliaments, and opposed to abolition of the rotten boroughs. B

is likewise evident, from his language, that he was a man of rank and fortune. this appears not only from his tone and manner, but from his express assertions: "My rank and fortune place me above a common bribe:" and to one of Woodfall's letters concerning the profits arising from the sale of the letters, he replies, "I am far above all pecuniary views." Lord Eldon declared in parliament that, if not a lawyer, he must have written in concert with the ablest lawyers; but, the great English lawyer Butler asserts that Junius commits gross inaccuracies in his legal phrases. Several incidental expressions, as well as his general tone, his intimate knowledge of persons and characters, show him to have been a man beyond middle life. He was evidently acquainted not only with the court but with the city (which was less usual in those days); with the history, private intrigues, and secret characters of the great; with the management of the public offices, with the proceedings of parliament (not then, as since, public); and also with the official underlings, through whom he sometimes condescends to lash their superiors. With this extensive information, he united a boldness, vehemence, and raucour, which, while he spared no one, stopped at nothing, and rendered him an object of terror to those whom he attacked. To use his own language, "he gathers like a tempest, and all the fury of the elements bursts upon them at once." "In raucour and venom," said Burke in the house of commons, "the North Briton is as much inferior to him as in strength, wit, and judgement. King, lords, and commons are but the sport of his fury." Grafton, Bedford, Blackstone, and Mansfield seem to be objects of personal resentment. Chatham and Camden were severely attacked in some of his earlier letters, though his tone in respect to them was changed in the latter part of his correspondence. His style is severe, concise, epigrammatic, and polished; his reasoning powerful; his invective unsparing and terrible.

Public suspicion, at the time, was fixed most strongly on Burke and Sackville; at a more recent period, the opinion that Sir Philip Francis was the author, gained many adherents. Among the many other shadows who have been raised are Charles Lloyd, a clerk of the treasury, and private secretary to Mr Grenville (doctor Parr thought him the author; but he died three days after the last letter appeared); Roberts and Dyer, who died before the letters were finished; Hamilton (single speech); Butler, bishop of Hereford (whom Wilkes suspected); the reverend Philip Rosenhagen; general Charles Lee, who, in conversation, once gave out that he was the author, and whose pretensions are supported in a work by Girdlestone; Wilkes; Hugh Macauley; Boyd, a writer of some talent (see Campbell's *Life of Boyd*); Dunning (lord Ashburton), who was solicitor-general at the time; Delolme; Glover; Horne Tooke, &c. Burke was strongly suspected in his day, but he spontaneously denied it; and, apart from internal considerations drawn from his temper, style and turn of thinking, it is sufficient to observe that, on several points, Burke and Junius were in direct opposition to each other. The former was a friend of Rockingham, the latter of Grenville; on the American policy and triennial parliaments, they were at variance; and Burke knew nothing of city politics, with which Junius was so familiar.

The opinion that Sir Philip Francis (died 1818) was Junius, has found many partisans, and was indignantly supported in Taylor's work—*The Identity of Junius with a celebrated living Character established*. The arguments are drawn principally from external considerations: his absence on a journey to be confined coincides with an interruption in the letters; his departure for India with a high appointment,

with their cessation; his receiving that appointment, without any apparent cause, just after being dismissed from the war office; his station in the war office, with all the details of which Junius is so familiar; his knowledge of speeches not reported; coincidences of thought and expression between passages of the letters and of speeches of lord Chatham, reports of which had been furnished by Francis, and with his own speeches, made after his return from India; peculiar modes of spelling, and of correcting the press; resemblance of handwriting—are also brought forward to establish the identity. But the internal argument is against the supposition: Francis was but twenty-seven when the first letters were written, and he never displayed, before or after, any proofs of a capacity or knowledge equal to the compositions of Junius. These circumstances have led to an hypothesis that, although he was not the author, he might have been the amanuensis of Junius.

Another candidate, whose claims are much more powerful than any previously mentioned, is lord Sackville (at one time lord George Germaine, and father of the present duke of Dorset). Sackville was strongly suspected at the time. Sir William Draper divided his suspicions between him and Burke, but finally fixed them on the former. His rank, fortune, temper, and talents concur to render it probable; the friends and enemies of Sackville and Junius are the same, and their political principles coincide. Sackville's unmerited disgrace is well known; his hostility to the king may have arisen from having been forbidden the court; Mansfield was a crown-officer at the time of his trial; Bedford was a connexion, and on bad terms with him; Grafton was a witness against him; Granby was second in command at Minden, and concurred in effecting his disgrace; Barrington was the organ of his dismissal. This opinion has been maintained in Coventry's *Critical Inquiry* (London, 1825), and, with additional proofs, in Junius Unmasked (Boston, America, 1828); but, although many striking coincidences have been pointed out, the proof is by no means complete in favour of this hypothesis. In the *Posthumous Works of Junius* (New York, 1829), with an Inquiry respecting the Author, the letters are ascribed to Horne Tooke. A late writer has started the hypothesis that Lord Chatham was Junius (*Essay on Junius and his Letters*, by B. Waterhouse, 8vo, Boston, 1831). A still more recent writer has made an ingenious attempt to show that lord Temple, brother of George Grenville, was the author of these celebrated letters. The fact that Grenville was the favourite of Junius, has often been mentioned, and it has also been suspected, for various reasons, that lord Temple was, in some way, connected with Junius; Butler (without suspecting Temple) mentions that the letters appeared to be written in a lady's hand, and that Wilkes once received a card from old lady Temple, in her own hand, which they agreed in thinking resembled the hand-writing of the letters. We have already cited a remarkable passage from the *Edinburgh Review* on the subject of Junius's political connexions, and the statement from the *Globe* seems to point out his family. George Grenville has himself been suspected to be Junius; but it is sufficient to observe that he died in 1770, when but a small part of the letters had appeared. The authorship is ascribed to lord Temple, in the work to which we refer, by Mr Newhall, of Salem, in Massachusetts (*Letters on Junius*, Boston, 1831), on the ground of the well established facts, that his political and personal connexions were the same; that the opinions of Junius, in regard to Chatham and some other persons, differed at different times; and that this difference agrees with the changes in

lord Temple's feelings towards those individuals; that the political principles of the two coincide: he also endeavours to show that Temple's talents, age, circumstances, style of writing and thinking, of which he gives specimens, render his hypothesis probable; and we would add, that, if it is not the true one, it is certainly embarrassed with fewer difficulties than any which has come to our knowledge; but *Non nostrum tantus componere lites*. The most valuable editions of Junius are those of Heron, a pseudonym (London, 1801, of which it is strange that we find no account in the English reviews of that day), and particularly of Woodfall, with notes and illustrations. A French translation by Parisot, with a commentary, was published in Paris, in 1823.

**JUNKS**; large, flat-bottomed vessels, from 100 to 150 tons burden, used by the Chinese. They have three masts, and a short bowsprit placed on the star-board bow. The masts are supported by two or three shrouds, which, at times, are all carried on the windward side. On the fore and main-mast is a sort of lug-sail, of cane or bamboo. Similar to these junks are the Japanese barks, which are eighty or ninety feet long on one deck, but have only one mast, that carries a square-sail, and forward one or two jibs, made of cotton.

**JUNO** (with the Greeks, *Hera*), the highest and most powerful divinity of the Greeks and Romans, next to Jupiter (the Greek *Zeus*), of whom she was the sister and wife, was the daughter of Kronos (Saturn) and Rhea Arcadia. Argos and Samos claimed the honour of her birth. According to Homer, she was educated by Oceanus and Thetis; according to others, by the Hours. Her marriage with Jupiter, on the island of Crete, was honoured by the presence of all the gods. According to Homer, Jupiter embraced her without the knowledge of her parents; and others say that he subdued her by artifice, on the island of Samos, and there married her. After he had loved her for a long time without any return, he once saw her without her attendants, wandering on the mountain of Thronax, and afterwards lying down to rest. He collected a dark cloud, and threw himself at her feet in the form of a cuckoo, trembling with wet and cold. She compassionately took the poor bird under her mantle; but the god immediately assumed his true form, and, in order to enjoy her, promised her marriage. Their marriage was not fortunate. The proud, ambitious, and jealous Juno could not bear the frequent infidelities of her husband; but he treated her with all that severity which, in ancient times, the husband was accustomed to use towards his wife. The ancient poets, particularly Homer, give us many instances of this kind. When Juno had driven Hercules, the favourite of her husband, to Cos, by a storm, Jupiter was so angry that he bound her hands and feet, loaded her with two anvils, and suspended her from Olympus. No one of the other gods could help her. During the Trojan war, having lulled Jupiter to sleep, in order to give the victory to the Greeks during his slumbers, she escaped with difficulty from the blows which Jupiter aimed at her when he awoke. In the oldest poetry, Juno is described as a divinity hostile to Hercules, appearing unpropitious to him, even at his birth, and opposing him afterwards in all his undertakings. Homer generalized this idea, and represented her as a malicious goddess, of whom he made use whenever a plan was to be interrupted, or an enterprise defeated. He describes minutely the art which Juno used to assist the Greeks, contrary to the command of her husband. She is also the malicious persecutor of the objects of Jupiter's amours (e. g., Latona, Semele, and Alcmena), and of their children by him. Among the

latter, Hercules and Bacchus suffered most. The Thebans likewise felt the effects of her hatred, because Hercules was born among them. She persecuted Athamas and his family, because he had educated the young Bacchus. All who assumed to themselves, or attributed to others, a superiority to her, experienced her vengeance. The beauty of Juno is elevated, majestic, and calculated to inspire awe: she wanted the soft, insinuating, and heart-touching beauty of Venus. In the Trojan war, she was the protector of the Greeks. She sometimes mingled herself in the combat: thus, e. g., Jupiter once allowed her to remove Mars, the protector of the Trojans, from the battle. No one of the goddesses dared contend with her in fight. Diana once attempted it, but her cheeks felt the strength of the mighty Juno. Her children were Hebe, Iphigeneia, Mars, and Vulcan. The last, however, she is said to have born without the assistance of Jupiter, a revenge for his producing Minerva from his own brain. According to some writers, she was also the mother of the monster Typhon; but others ascribe him a different origin. Four different ideas are associated with Juno. According to the Orphic doctrines, she was the symbol of the lower air; Jupiter was of the upper air, or of the air in general. With this was joined another idea, derived from the Pelagic religion at Samos, which represented her as the queen of the gods. To this was added the Phœnician notion; the Venus Urania, by which name the Phœnicians worshipped nature, being confounded, in Greece, with Juno. As such, she was particularly worshipped at Argos. Finally, the poets gave her the character of a malicious goddess, who counteracted the projects of Jupiter and other gods, and heroes and men. She was worshipped in all Greece; but her principal seats were at Argos, in the vicinity of which was her famous temple, the Heraion, and at Samos, the place of her birth and marriage; hence one of her epithets was *Samosia*. The Roman Juno was represented, on coins, with a crescent on her head, and her hands resting on two snakes. The companions of Juno were the Nymphs, Graces, and Hours. Iris was her particular servant. Among animals, the peacock, the goose, and the crane were sacred to her. Her usual attribute is the ægis, diadem, formed like a long triangle. She also bore a veil bespangled with stars, either as a covering to her head, or hanging loosely behind her. (On a coin in the collection of Stosch, she appears to wear majesty, seated on a throne, having at her back, on each side, the sun and moon, and over her head the planets, to signify that she is the queen of heaven.) She is drawn in a carriage by two peacocks. The statues of Juno, among the ancients, were not very numerous, and even during the time when sculpture was in its most perfect state, the Greeks possessed no particularly celebrated statues of her. Most of the portraits of Juno, on gems, are by the best artists at the time of the Roman emperors. She had the same character among the Romans as among the Greeks. They called her generally *Juno Regina* (Regia), *Pronuba Matrona* (as protectress of betrothed virgins), *Lucina* (q. v.), and *Ithyphyla*. She had several temples in Rome. The first days of every month, and the whole of June, were sacred to her. On the planet of this name, see *Planets*.

**JUNTA** (Spanish, an assembly), in Spain: a council of state. There were, formerly, but now the royal junta of commerce, the mint and the *real junta general de comercio, moneda, medidas, y dependencias de estrangeros*), and the board of the tobacco monopoly (*real junta de tabaco*). An assembly of the estates of the kingdom was called the *cortes*. But in 1808, Napoleon suppressed it.

gether the notables of the kingdom, under the title of a *junta*, to the number of 150 members; of whom 50 were to represent the spiritual, and 100 the secular interests of the country. Only ninety members, in fact, appeared, and these without sufficient powers—a circumstance, however, which embarrassed him little. The junta was organized June 15, 1808, under the presidency of D'Aganze, minister of finance, and unanimously accepted the new constitution. But when king Joseph was obliged to leave Madrid, August 1, a new junta was assembled, composed of the principal leaders of the insurrection. It consisted at first of twenty-six members. The count Florida Blanca was its president. Its number was afterwards fixed at forty-four. The advance of the French drove this junta to Seville, whence they subsequently retired to Cadiz. Besides this central junta, there was, in every province, not subjugated by the French, a provincial junta, subordinate to it. See *Spain*.

In English, the word *junto* is used as a term of reproach, for a cabal or faction.

JUPITER (in Greek, *Zeus*); son of Saturn and Rhea. The Greek name of his father being *Kronos*, he is sometimes called *Kronion* and *Kronides*. He is the brother of Vesta, Ceres, Juno, Neptune, and Pluto. In the different periods of Grecian history, very different notions were entertained respecting this god. The Pelasgi honoured him, from the most remote times, as the symbol of nature. His oracle was at Dodona, and hence he is called the *Dodonian*, *Pelagic king*. In the Orphic religion, Jupiter was a physical symbol, and denoted the upper air, the æther; and Juno, the symbol of the lower air, was connected with him as sister and wife. Hence the following Homeric fable is explained. Juno, Neptune, and Apollo wish to bind Jupiter; but Thetis calls the hundred-armed Briareus to his assistance, who, by his mere presence, prevented the gods from carrying their plot into execution (the contest of the elements, in which the æther would have been in danger of being overcome, had it not at length gained the victory through its strength, Briareus). Thus also we may explain, symbolically, the fable, that Jupiter once boasted that he would let down a chain from heaven, upon which all the gods might hang, and still would not be able to drag him down; but he would draw them, together with the earth and sea, up to himself, and then, winding the chain around the top of Olympus, would leave them swinging in the clouds (the combined efforts of all the lower elements are not sufficient to draw down the æther from its seat). From the symbol of the æther was evolved the poetic conception of Jupiter, as ruler of the æther and the upper air. In reference to this, he has the following surnames, the *lightning-loving*, the *cloud-collecting*, the *high-seated*, the *far-seeing*, the *loud-thundering*, the *cloud-compelling*. A higher idea makes him the father of gods and men, as indeed Homer calls him. Still this is not the idea of a supreme being, the creator of the world, which first arose at a later period. The more common idea, at this time, was that of Jupiter Herceus, who, being only the governor and protector of houses, families, and their possessions, or of a whole people and a particular territory, was of course nothing more than a local deity. He is also the ruler and director of the fates of men, and holds in his hand a balance, in which he weighs out to each one his portion of good and of evil. Two urns also stand in his palace; in one of which is evil, and the other good. Sometimes he gives to mortals a lot mingled from both; sometimes drawn from one alone. But, nevertheless, he himself subject to Fate, an unknown being, rapped up in obscurity. He is the wisest of gods

and men. Minerva sits ever at his side. He forms his purposes without the assistance of any one, and to whomsoever he does not disclose them, they remain inscrutable. He aids man with his counsel, and from this is called *Mnēstēs*, the *giver of good advice*. He is true; his promises are irrevocable and inflexible. He knows the fates of men. He hears those oaths of mortals which they swear by him, and punishes perjury in the severest manner. All injustice and cruelty is hateful to him. Whoever will not listen to a suppliant offender (*Isētes*), and forgive him, him Jupiter (*Istētesios*) punishes. He is kind and benevolent, and wishes men to be so likewise to each other. Hence he is called *Jupiter Euseos* (the protector of strangers).

These ideas of Jupiter, which are found in Homer and in the poets of his time, although as yet limited by local circumstances, were in after times more fully unfolded, in proportion as the intellectual cultivation of the Greeks increased, and a purer philosophy began to be diffused. With this are connected those historical traditions, according to which Jupiter was born and bred upon mount Ida, in the island of Crete; for an oracle of Uranus and Terra had counselled Rhea to bring forth her son upon that hill, lest he should be devoured by Saturn. Different traditions assign his birth to different places; some say that it occurred at Messene, others at Thebes, Olenus in Ætolia, Ægæ in Achaia, upon the hill Lycetos or Dictæ in Crete, on mount Lycæus in Arcadia (where the cavern was shown in which his mother bore him). Equally different are the accounts respecting the place where he was educated. According to Homer, Terra educated him, and concealed him during the night, in a cave of the woody mountain Argæus; doves brought ambrosia to him. The Arcadians and Messenians say that he was educated by the nymphs, who received him from the Curetes, and bathed him in the fountain Clepsydra. According to other accounts, his mother intrusted the child to the care of the Curetes, and these gave him to the nymphs Ida and Adrastea, to nurse, whilst they themselves, by a continual clashing of their shields, prevented Saturn from hearing the cries of the child. Instead of Jupiter, Saturn is said to have swallowed a stone swathed in a goat's hide and anointed with honey, which they gave him. According to others, he was educated by the daughters of the Cretan king Melissus, Amalthea, and Melissa, who nursed him with the milk of the goat Amalthea, one of whose horns Jupiter changed into the horn of plenty. He grew very rapidly. Whilst he was yet but a year old, he was already able to afford assistance in the execution of a scheme which his mother had formed against his father. From Metis (goddess of wisdom), Jupiter received an emetic which he gave to Saturn. The potion worked so well, that he threw up all the children which he had swallowed, even to the stone which he had swallowed last. This stone Jupiter deposited at the foot of Parnassus, near Pytho, for a memorial. He proceeded now to dethrone his father. The oldest sons of Uranus and Terra, the hundred-handed giants, and the Cyclops, were fast bound in Tartarus, and the monstrous Campe kept guard over the prisoners. Jupiter killed the monster by the advice of Terra, and set free the prisoners. Out of gratitude, they armed Jupiter with the lightning, which, until that time, had lain concealed in the earth; Neptune with the trident; and to Pluto they gave a helmet which rendered the wearer invisible. He then dethroned his father, and castrated him with the same weapon which the former had before used on Uranus for a similar purpose. The Titans were not contented with this change of government, and there arose a ten years' war between

them on one side, and the children of Saturn and the hundred-handed giants on the other. (See *Briareus*.) The theatre of battle was the hills of Olympus and Othrys. From the latter fought the Titans, from the former the new gods. At length the latter conquered, and the Titans were hurried down to Tartarus. Jupiter, having now obtained full possession of the sovereignty, shared his father's kingdom by lot with his brothers; he himself receiving the heaven and the earth, Neptune the kingdom of the sea, and Pluto the infernal regions. But fearful monsters threatened the new gods with destruction. Terra, angry that her children, the Titans, should be kept imprisoned in the depths of Tartarus, gave birth to the dreadful giants who rebelled against the new gods. These were conquered by the aid of Hercules. But Terra, still retaining her anger, bore to Tartarus, Typhœus (Typhaon, Typhon), the most frightful of all the monsters, whom Jupiter conquered with the greatest difficulty. According to some, Jupiter pursued him with his lightnings and sickle, until, at length, on a hill called *Cassus*, they joined battle. Typhœus wound about Jupiter with his dragon folds, flung him upon the ground, and with his own sickle cut out the tendons of his hands and feet, dragged him into the Corycæan cavern, and stationed a dragon to keep watch over him. But Mercury and Ægipan (a son of Jupiter and Æga, Pan's wife, or a foster brother of Jupiter) freed Jupiter by stealth from the dragon, cured him, and set him upon a winged chariot, from which he hurled his lightnings down upon Typhœus. At Nisus and upon Hæmus, they fought with each other; but at length Jupiter gained the victory, and crushed the bleeding monster beneath Ætina, or the island Pithecusa.

Jupiter now found himself in quiet possession of the sovereignty, which was solemnly surrendered to him by the other gods, to each one of whom he therefore gave a reward. From this time he was king of the gods—an idea which seems to have originated when Greece had as yet only her smaller kings. And even as these often chose from among themselves a universal king or governor, who should hold the first rank (as, for example, Agamemnon in the Trojan war), so, also, according to the representations of the poets, did the gods. They chose Jupiter their king and leader: he had therefore the right, on important occasions, to assemble them in his palace. In the Trojan war, he forbade the deities from taking further part in it, and threatened to hurl any transgressor of his command down to Tartarus. The king Jupiter is formed, by Homer, after the exact fashion of the Grecian kings of the period, and his whole character is painted in exact accordance with the characters of the old Greek heroes—rude, wild, and passionate. A scourge is even ascribed to him, with which, as king, he may administer chastisement. This idea was borrowed from the Egyptians, amongst whom the scourge was an emblem of kingly power. As ruler of the earth, Jupiter particularly directed his attention to the race of men, which he exterminated, because it had become corrupted and vicious, and then created another and better from the trees. He caused Prometheus, who had stolen fire from heaven for men, to be bound by Vulcan on the Colchian Caucasus, whilst his liver was to be ever preyed on by a vulture. He killed Esculapius with his lightnings, because, by his arts of healing, he had unpeopled the realm of Pluto; and when Phœbus, to avenge his son, slew the Cyclops who had forged his lightnings, he banished him a long time from heaven to earth. He punished with death Salmoneus, who imitated his thunder; Idas, who wished to slay Pollux; Capaneus, who was the first to scale the walls of Thebes; and afterwards, also, the Curetes,

who, at the persuasion of Juno, had covered the young Epaphus, and the Achaian river-god Æacus, who had endeavoured to regain his daughter, whom Jupiter had carried off. He went through the same punishing the wicked, and rewarding the good. His peculiar servants were the Horse and Mercury. Ganymede, who took the place of Hebe, was cap-bearer to him and the other gods. His palace is on Olympus. Themis or Dike sits on a throne beside him. His first wife was Metis, a daughter of Uranus the wisest of all the deities. But when Uranus and Terra foretold to him that she would bear a child who should deprive him of his sovereignty, he devoured her during her pregnancy; and thence it came to pass that Minerva, some time after, was born from his head. His second wife was Themis, a daughter of Uranus and Terra, who bore him the Horse and Perce. His third wife was Juno. Among the goddesses he also loved Dione, a daughter of Æther and Terra, and was by her the father of Aphrodite. At a later period, Menosyne, daughter of Uranus and Terra bore him the nine Muses, he having spent nine years in her embraces; Ceres, his sister, became by her the mother of Proserpine; Eurynome, daughter of Oceanus and Thetis, became mother of the three Latona, daughter of a Titan and Phœbe, mother of Apollo and Diana. Among his mortal mistresses were Danaë, daughter of Acrisius, and mother of Perseus; Niobe, daughter of Phœbus, the first among mortals whom Jupiter loved, mother of Argus the third king of Argos; Maia, daughter of Atlas and mother of Mercury; her sister Taygete, mother of Lacedæmon, and the third sister Electra, mother of Dardanus; besides these were Semele, daughter of Cadmus, and mother of Bacchus; Europa, daughter of Phoenix or Agenor, and sister of Cadmus, mother of Minos, Sarpedon, and Rhadamanthus; Cleo, daughter of Lycôn or Nycteus, mother of Arcas; daughter of Inachus or Argus Panoptes, mother of Epaphus; Leda, daughter of the Atolus king; Thetis or Glaucus, mother of Helen and Menelaus; Ægina, daughter of the river-god Æsopeus and mother of Æacus; Antiope, daughter of Nycteus, mother of Amphion and Zethus; Elara, daughter of Orchomenus, and mother of the giant Tityos. The last of his mistresses was the beautiful Alcmena, the mother of Hercules. The Nymphs are also regarded as the daughters of Jupiter. At a later period, by his rape of the beautiful Ganymede, he gave the Greeks the first example of the art of boys.

Jupiter had many oracles in Greece: for instance at Dodona, at Olympia, although the latter after a short time ceased, and one in a holy grove on Mount Ida in Crete. His most famous temple in Greece was that of Olympia or Pisa. He was also especially honoured at Dodona in Epirus, on Mount Cassius in Egypt, in the city Nemea in Argolis, on Mount Athos and Dictæ, and many other places. In this way we have many of the surnames of Jupiter explained. By the Romans he is called *Jovis*, *Elivius*, *Sator*, *Capitolinus*, and the like. His usual attribute is the thunder-bolt, which he ever holds himself in his hand, or which the eagle bears at his side. He is always attended by the eagle, sometimes by the beautiful Ganymede. He is usually represented with a crown and sceptre. His countenance displays seriousness and majesty, mingled with benevolence and serenity. Of the statues of Jupiter we have received but a few from antiquity, and none of the first rank. By far the most beautiful representations of him are found upon gems, which represent to us the king of the gods in the different parts of his history; sometimes only the bust, sometimes the whole figure; sometimes alone, at other times

with other figures. That celebrated masterpiece of Grecian art, the statue of Jupiter Olympius, by Phidias, is indeed lost to us. But it is highly probable that in the excellent heads on gems, the principal traits of it are preserved. Upon a gem in the cabinet of Stosch, the beholder admires the deep seriousness mingled with a heavenly mildness, which is spread over his whole countenance, and the beautiful growth of hair falling down, not like the crisped locks of youths, but in gentle undulations of a ripe, manly age, closely resembling the mane of the lion, the king of beasts. Upon another gem, Jupiter is enthroned in an arm chair, as king of heaven and earth. The moon and stars are round about him, the globe is in his right hand, the sceptre in his left, and a diadem on his head, to point him out clearly as the supreme ruler. The lower part of the body is covered. The eagle at his feet sits looking up to him, awaiting his commands. When Jupiter stands, he is generally naked, because he is then occupied in a way which makes clothing an incumbrance. Bulls and eagles were usually offered to him; the oak and beech trees were sacred to him. In the second month of every fifth year, the Olympic games were celebrated in honour of him. Besides the Homeric and Orphic hymns in honour of Jupiter, we have one by Callimachus and Cleanthes. We would remark that the ancients reckoned many different Jupiters. Varro gives 300 of that name, and Cicero three, as the most distinguished—the sons of Æther, of Cælus, and of Saturn. To the last, the actions of all the rest were finally attributed.

*Jupiter Ammon.* Sufficient has been said for the limits of this work, on this great deity of the Egyptians, in *Ammon*, and in *Egyptian Mythology*. In the article *Hieroglyphics*. We will only add, that in the *Transactions of the American Philosophical Society* (Vol. 4. new series, No. 1), a publication not yet out when the above-mentioned article was prepared, Mr Hodgson directs the attention of the etymologist for the origin of the word *Ammon* to the Berber word *Aman*, water (the very contrary to *amut*, sand, the word from which *Ammon* is generally derived). (See also Champollion's *Tableau Général*, prefixed to his volume of plates, No. 39, a.)

*Jupiter*, in astronomy. See *Planets*.

**JURA**; one of the Hebrides, or Western Islands of Scotland, situated to the north-east of the island of Islay, and opposite to the district of Knapdale, in Argyshire, to which county it is annexed. It extends fully twenty-six miles in length, and is on an average seven broad, containing 58,500 Scots acres, of which only 3000 are arable. It is the most rugged of the Western Isles, being composed chiefly of huge rocks, piled on one another in the utmost disorder, naked, and incapable of cultivation. The mountainous ridges terminate in three or four similar peaked mountains, called the *paps of Jura*. The only crops are oats, barley, potatoes and flax; the chief manure is the sea-weed, which is cast ashore. There is only one small village, called *Jura*. The Gaelic language is spoken in the island. Population, in 1831, 1312. See *Hebrides*.

**JURA**; a chain of mountains about sixty leagues in length, and fifteen in breadth. It is a continuation of the Savoy Alps (q. v.), extending from the Rhine, near Bale, to the Rhone, about ten miles below Geneva. By the low range of mountains in the Pays de Vaud, the Jura is connected with the lofty Alps of Berne. It stretches towards the north in several long ridges between France and Switzerland; the ridges then separate, and the eastern one, which is the principal, is continued through Neuchâtel and the canton of Soleure, and terminates on the eastern side of the Frickthal, in the canton of Aargau, on the

Rhine, where, on the German side, the Schwarzwald or Black Forest is a continuation of it. The western branch extends farther to the north, and takes the name of the Vosges. Jura has neither the pointed summits nor the perennial snows of the highest peaks of the Alps. One of the highest peaks, mount Reculet, is elevated 5310 feet above the level of the sea, and the Dole, 5185 feet. The French department of the Jura, a portion of Franche-Comté, on the Furieuse and the Doubs, furnishes silver, copper, iron, lead, marble, and salt. The chief town is Lons-le-Saulnier.

**JURGURA** (anciently, *Mons Ferratus*); a mountain of Africa, in Algiers, supposed to be the highest in Barbary; twenty-four miles S. of Dellys, sixty S. E. of Algiers. It is at least twenty-four miles long; and, if we except a pool of good water, bordered round with arable ground, that lies near the middle of it, the whole, from one end to the other, is a continued range of naked rocks and precipices. In the winter season, the ridge of this mountain is always covered with snow.

**JURY.** [Written by a civilian.\*] The right of punishing is inseparable from the executive power in a state; but, since the penal authority has to decide respecting the property, freedom and life of citizens, the executive or highest power may easily degenerate into despotism, and the relation of the citizen to the government into slavery, if it can punish at will. It consequently becomes an object to deprive the government of the will and power to punish unjustly. Now, since, in every case of punishment, a double question is to be answered—first, whether the accused committed the act with which he is charged, and, secondly, if he is guilty, what consequences do the laws attach to the deed, and what punishment must be inflicted—the executive power will be sufficiently restricted, if we leave it to answer merely the last question, and leave the decision of the first to a separate, independent authority. This can neither be limited to single individuals, nor to a permanent college. Both are too much subject to the influences of the supreme power. The mass of the people, alone, is not to be corrupted. But, since the mass of the people cannot sit in judgment, and it is also known how little impartial justice is to be expected from the multitude, when their own interest is concerned, this agency must be committed to sworn substitutes, chosen for single cases, or only for short periods, in order that the popular tribunal may not degenerate into an established office. These substitutes, as they are not determined beforehand, cannot become the object of corrupting influences, which, though they may find access with some, hardly can with all. In these views lie the foundation and essence of juries; namely, of the petty jury in England, and of the *jury de judgment*, in imitation of it, among the French. In the former country, the love of freedom proceeded still farther, and on account of the mischief that may be produced by complaints, invented the grand jury, consisting, likewise, of sworn representatives of the people, whose function it is to decide respecting the admissibility of complaints, and whether, in conformity with them, a criminal prosecution is to be instituted against any one. Its coun-

\* The first portion of this article as far as page 283 is translated from the German *Conversations Lexicon*, and was written by a German civilian accustomed to the juridical practice of countries where the civil law prevails, and where the trial by jury is imperfectly understood, and, if introduced at all, has been imperfectly administered. It has been retained, because it has been thought that the views of the continental jurists on this subject would be curious and instructive. The writer, it will be seen, considers the trial by jury almost solely with reference to criminal cases.—The remainder of the article was written by an eminent American jurist.

terpart existed in France till 1809, under the name of *jury d'accusation*. To this essential character of a jury are united several properties necessary to its perfection.

Not only must citizens sit in judgment on citizens, but the greatest possible equality of rank is to be sought, between the judges and the party to be judged, in order that the interests of different ranks may not give rise to injustice, partiality, or false decisions. In England, where all ranks, below the hereditary peers, are by law equal, and without exclusive prerogatives of rank or birth, all persons not born peers of the land (for they, as an intermediate part of the hereditary government, between king and people, have their equals, and, consequently, their jury only in the house of lords) are tried by the same jury. In the ancient German courts, which, in substance, were juries, the equality of birth between the judge and criminal was most strictly observed; not, however so much that no inferior person could be judged by a higher, as that no higher could be judged by an inferior.

The jurors cannot well be chosen otherwise than by a public officer—in England, by the sheriff. To guard against all danger of partiality and undue influence, the person arraigned has the right of rejecting a portion of the jurors empaneled. The right allowed to the prosecutor is more limited. In England, the former may [in capital cases] reject twenty, and in crimes of high treason, thirty-five. The public prosecutor cannot challenge any one without declaring cause.

A jury, which, in most cases, must consist of men of little education, cannot be guided in their conclusions by legal rules of evidence, but only by their general impressions from the whole train of circumstances; and, on this account, its verdicts are not proper subjects of revision. In England trial by jury is extended even to civil cases, especially for settling certain matters of fact; for instance, of possession, of estimating the amount of damage, &c.

All the operations, examinations, and other processes necessary in a criminal trial, are to be performed in the presence of the jury. To refer them for information to a protocol, or to the reports of an officer, would involve difficulties, and, at all events, leave them exposed to the errors which might arise from the subjection of the reporting officer to foreign influences, and thus defeat the essential object of trial by jury. With the French constitution, the trial by jury was spread on the continent, and excited, in many persons high admiration. It has been proved by Feuerbach, in his classical work on this subject (Landshut, 1813), that, in a political view, trial by jury has a value only in particular constitutions, in which its political advantages may induce us to overlook its defects, when considered merely in reference to criminal jurisdiction. Political objects make the trial by jury necessary in democracies. Intrusted to a single magistrate, or to a permanent authority, the criminal power would open an immediate avenue to sole dominion, or to aristocracy. Equally indispensable is it to a mixed constitution, like the English; for it would become either a pure monarchy, democracy or aristocracy, if the immense preponderance of the penal power should be committed solely to the monarch, or to one of the powers counteracting and restricting him, the people or the body representing the national sovereignty. On the other hand, it is apparent, that in a constitution where the monarch is absolute, the political advantage of a jury disappears. No constitution, no personal freedom of individuals can, in such case, be defended by juries, since the ruler can abolish it at any moment, or, in particular cases, render it inefficacious by a special commission. The most eloquent example is that of France in late years. The establishment,

moreover, of trial by jury in a pure monarchy, already confirmed by long permanence, is not only null, but superfluous, inasmuch as the ruler can do nothing more by injustice, but may lose every thing. But how far does the trial by jury satisfy the demands which are made of criminal jurisdiction? How far is a certain determination of guilt or innocence to be expected of it? 1. Can we believe the jurymen, who is accustomed to move only in the circle of common intercourse, can we believe him possessed of sufficient sagacity to look through the most compacted relations, which often occur in criminal trials, permitting neither aversion nor predilection to influence his verdict? Certainly not. But to attempt to abolish the evil by means of permanent jurors, who should acquire ability by practice, would be to destroy the essential character of juries. Add to this, that in the oral proceedings in the presence of the jurors, every means is afforded for the operation of sophistry, and the excitement of the passions, and that the various grounds of defence or accusation, often infinitely numerous, can in no wise be fairly examined and compared with each other—a process possible only when the judge forms his opinion from written documents. In every case, the last impression of a jury will be the decisive one. The charge, by which, after the termination of the debates, the presiding judge, versed in the law, seeks to guide the deliberations of the jury, and aid their untaught judgment, may contribute, indeed, to remove this and the deficiencies remarked below, but the effect of it is very inconsistent with the object of jury trials; for it makes him, in most cases, master of the judgment. One may generally foretell, in England, the verdict of the jury from the charge of the judge. 2. Experience confirms it, and it lies in the nature of things, that the jury regularly hesitate, even against their convictions, to give a verdict of guilty, when it exposes the party to a punishment, in the public opinion, more severe than just. To common penetration, it is extremely difficult to separate the fact from its legal consequences. This evil is seen to be in some degree necessary, especially in England, where the criminal code has not kept pace with the times, and a very slight theft is punished with the halter. 3. The question of guilt or innocence is not one of pure fact, but also a legal question, and presupposes, in every case, a knowledge of criminal law. To be able to say whether any one has committed a violent robbery, it must first be known whether he has done the act which the accuser asserts, and, secondly, whether the act had those characteristics, which the laws require to constitute the crime. But if, to remedy this evil, the jury should be restricted to the question whether a certain act had been committed or not, its object would be destroyed, and the authority to which is committed the decision of the point of law would be left to its free will, since it might make that act any crime it pleased. In England, recourse has been had to the dangerous practice of allowing the jury, when they find the accusation in a legal view but partially founded, or regard the crime committed as less heinous than the one charged, to give a verdict partly of acquittal, partly of condemnation, such as guilty of manslaughter, but not of murder. If the jury agrees on the point of fact, but cannot remove their doubts respecting its legal character, they have to leave the decision to the judge. But will not the jury trust to their penetration more than is just? Does not the presiding judge become absolute? Some might, indeed, be inclined to make it a decided advantage of juries, that the accused is tried by judges who are his equals, and from whom, it would seem, may be expected a juster decision, more conformable to his peculiar situation, than from others. But, in the first

place, the poorer class of people, who, above all others, all the annals of criminal trials, must be excluded from the jury by reason of their want of information and comparatively small interest in the public welfare, by which means that equality is, in most cases destroyed (thus, in England, to be a juror, a person must have a certain income; the same is the case in France, where attention is also paid to particular circumstances of rank); so that, from the infinite gradations and varieties of property, education, opinions, and innumerable outward circumstances instead of full equality, the greatest inequality often subsists between the jurors and the accused. The various means by which it has been attempted, in France, to remedy the defects of the jury, and which, nevertheless, have produced no better criminal jurisdiction, satisfactorily prove their entire insufficiency in this respect. See *Assizes*, and *Appeal*.

I. *History of the Institution.* It has evidently been, from the beginning, a truly popular trial, and not, as Rogge has lately asserted (*Gerichtswesen der Germanen*, 1820), a modification of the ancient process of compurgation. These institutions—compurgation and jury—have, indeed, many external similarities, and may, in some cases, have become blended with each other; but, in their nature, they are entirely separate. This appears evident from the circumstance that, in England, juries and compurgations occur at the same time. Criminal actions against the clergy were prosecuted under the direction of the bishop, with twelve of the clergy as jurors, but were begun by the accused with twelve compurgators swearing to his innocence, and commonly ended in his acquittal, till an end was put to this disorder by law, in 1576. (See Blackstone's *Comment. on Laws of England*, vol. iv.) It has long been known in Germany, and has lately been proved by Feuerbach (*Betrachtungen über die Mündlichkeit und Öffentlichkeit der Gerichtsgeschäfte*, 1825), that the most ancient constitution of the German laws, and in Bavaria as late as the fifteenth century, consisted in the men of the communes finding judgment under the guidance and protection of an officer. As there must be some fixed number, that of twelve is as good as any other, and has been preferred from time immemorial; but the agreement of the twelve jurors consisted, at first, in many cases and places, in the circumstance, that the votes of all the men present, and capable of giving an opinion, were asked, and the matter decided as soon as a majority of twelve votes was obtained for an opinion. One person could, therefore, cancel the vote of another juror, by declaring himself of another opinion, and commanding the juror to leave his seat. Some traces of this regulation are still to be found in England. In the house of lords, the whole body of nobles vote; but a valid condemnation is obtained only when a majority of twelve votes is declared for conviction. But in the courts of assizes, the place of absent jurors is immediately supplied from the people present, and if these twelve cannot agree, according to the original constitution, the trial must be by new jurors, who are chosen from time to time till an unanimous vote of twelve is obtained. In important causes in the county courts, all the free-men of the county were, in former days, summoned, which is termed judgment *per omnes comitatus probos homines*. (Reeves' *History of the English Law*, 1814, vol. i. 84.) But it was very naturally soon found better to summon only a fixed number of men to this service, and thus arose the number of twelve, who could only unanimously give a valid decision. The oldest vestige of this change is found under Henry II., in the constitutions of Clarendon, in 1164, and of Northampton, in 1174. Contests about landed property, as well as criminal accusations, were to be

decided by the oath of twelve respectable men of the neighbourhood (*per sacramentum duodecim militum de hundredo, or liberorum legalium hominum de vicineto*). From this time, the trial by jury has remained essentially unaltered in England, and has gradually become the only form of process, partly by the abolition of the criminal courts which judged without jury, partly by the abrogation of the methods of criminal prosecution in which no trial by jury existed. Of the last, there remains only the pronouncing of punishment in the way of legislation, termed an *attainder* (*attinctura*), or *bill of pains and penalties*. There were, besides, several other ways of terminating a criminal trial without a jury, but between which, not the accuser, but the accused, was entitled to choose. In the times of the Anglo-Saxons, the ordeals of red hot iron and boiling water were in vogue, besides which there was the consecrated bread. The clergy prepared a piece of bread or cheese, an ounce in weight, which was easily swallowed by the innocent, but which stuck in the throat of the guilty, and choked him. Of such a morsel, Godwin, earl of Kent, died in the reign of Edward the Confessor; and, according as the accused was suspected or hated, it was well known how to prepare the morsel. Under the Norman dominion, this ordeal was supplanted by the wager of battle. The wager of battle (*vadiatio duelli*) was used even in civil cases, and, according to the most ancient custom, it depended on the accused, if the accuser had supported his accusation by witnesses, to choose whether he would have recourse to this means, or swear to his innocence with twice as many compurgators as the accuser had produced, though not above twelve. This was called *vadiatio legis* (wager of law). In civil causes, the wager of battle disappeared in the thirteenth century, when Henry II. introduced into the assizes a trial by jury. But in penal prosecutions, on the contrary, it continued much longer. The accused is still asked how he will be tried; and, though the answer—"by the law of the land," or "by the country" (*per legem terre, or per patriam*)—has become a mere formality, yet, as late as 1819, a singular trial for murder took place, in which it stood at the option of the accused to challenge the accuser to the wager of battle. (See Kendall's *Appeal of Murder*, London, 1819, and *Appeal*.) A court of justice, moreover, formerly, existed in England, which judged without jury, called the *star-chamber* (*camera stellata*)—a name respecting the derivation of which antiquarians are not agreed. It consisted of some lords, both temporal and spiritual, members of the privy council, and two judges of the supreme court of Westminster, and had properly jurisdiction only of some particular cases, rebellion, perjury, the official misconduct of sheriffs, &c., but extended its jurisdiction farther and farther, and became, especially under Henry VII. and Henry VIII., an instrument of the most arbitrary power. After it had long been a subject of terror and hatred, it was entirely abolished under Charles I., in 1641. The trial by jury has since been regarded in England as one of the fundamental pillars of the constitution. By the Habeas Corpus act (see *Habeas Corpus Act*) of the reign of Charles II., greater security has been provided, that the trial by jury shall be withheld from no one; it is only to be lamented, that the petition for such an order is attended with extraordinary expense.

II. *History of the Jury in France.* In the article *France*, some of the cruelties are mentioned, which are chargeable to the administration of penal justice in France before the revolution. Judicial despotism, united with ignorance and corruption, was exhibited in horrid forms. The laws were severe. The ordi-

nance of criminal procedure of 1670 was written in blood, giving up the accused to the arbitrary will of the judge, and denying him the aid of counsel, excepting in a few cases (*Tit. 14. sect. 8*); admitting a double application of the torture (the *question préparatoire*, to extort from the accused a confession of his own guilt, and the *question préalable* before execution, to compel him to reveal his accomplices); and allowing any judge, even the patrimonial courts, to institute a process without any statement of the ground of suspicion. The judges were even more severe than the laws. Their ignorance and carelessness occasioned mistakes and abuses, which their pride and the clannish spirit of the higher classes prevented from being rectified, and under the operation of which crowds of innocent persons lost liberty, property, reputation, and even life. Even the most atrocious criminals, Damiens, for instance, could not be legally sentenced to such cruel torments as this offender actually underwent, when torn to pieces by wild horses. All the districts, therefore, in 1789, were unanimous in desiring that the judgment in criminal cases should be made dependent on the verdict of a jury. In fact, such a provision was introduced into the constitution of September, 1791, and on this subject there was hardly any difference of opinion. The form of the English institution was followed,—a grand jury being appointed to find bills of accusation, and, after the conclusion of the process, which was to be public and oral, the question of fact was to be determined by a jury of twelve persons. There were to be, also, as at present, justices of the peace, clothed with proper judicial authority only in cases of minor importance and disputes respecting the right of possession; and likewise district courts, who should exercise a mutual appellate jurisdiction in regard to each other's decisions. The judges were to be chosen by the people, to remain six years in office, were to be re-eligible at the end of this period, and to be paid, scantily indeed, by the state, being prohibited from receiving any fees. These provisions were made by the law of Aug. 24, 1790, respecting the organization of the courts. An ordinance respecting criminal jurisdiction of Sept. 29, 1791, a penal code of Oct. 6, 1791, and the regulations for the conduct of criminal prosecutions, Oct. 21, 1791, completed this new system, which has been subsequently retained in its fundamental principles, though not without undergoing essential alterations, by which a portion of the benefits, that are ascribed to the constitution of English criminal courts, was lost again, and the influence of the officers of the government on the administration of justice (it is said) improperly enlarged. The criminal courts were at first derived from the district courts, the judges sitting alternately in the criminal courts of the department. One of the judges was director of the jury, drew up the indictment, and assembled the jurors. The jury of accusation (*d'accusation*) consisted of eight members, three voices for the accused being sufficient to reject the complaint. This jury of accusation is now entirely abolished in the new criminal ordinance of November 17, 1808. (See *Codes les Cinq*.) The criminal courts for more important causes (*cours d'assises*) are now deputations of the king's court (*cour royale* or *cour d'appel*), and the decision respecting complaints is committed to a division of the *cour royale*. The liberty of the accused to hold consultation with counsel is less restricted by the new laws than by late practice. According to a very doubtful interpretation of the article 302 of the act of 1808, to regulate criminal process, the counsel is allowed access to the accused only a few days before the beginning of the public prosecution. And, in some cases, as in libels, the definitive

decision is taken from the jury, and given to a police courts. To require the unanimous agreement of the jurors to a verdict, which, even in England, often attended with great difficulties, and leads to striking inconsistencies, was soon found everywhere impossible in France. The simplicity of the English process, which, at the end of the proceedings, leaves to the jury the verdict of guilty or not guilty, it was found in France impracticable to imitate. In England, only the most important witnesses are brought forward, and a day, or, in very complicated cases, three or four days are sufficient to complete a trial, and consequently no uncommon powers of mind are required to retain the testimony in the memory. But, in France, even the most unimportant testimony is admitted. Hence several hundred witnesses are sometimes brought forward, and more weeks are spent in a case than there would be days employed in England. It having been found absolutely impracticable to insist on unanimity in the jury, it has been resolved to assume the simple majority of seven against five, as decisive. But in that case the court itself is obliged to deliberate on the same point and an acquittal takes place, if the majority of the judges coincide with the minority of the jurors, so that the numbers of voices in favour of the acquittal equal those for condemnation. The courts have also the right to set aside the verdict of the jury, if it appears to them to rest entirely on error; but this must be their own free act, and cannot be proposed by any one. A simple majority of jurors decided the case of Fonk, and, at Paris, 1823, that of doctor Castaing, indicted on a charge of poisoning. Among the objections made to the new French criminal process is the excessive power committed to the president. In England, the examination of witnesses is carried on by the prosecutor and the counsel for the defendant, but in France, the president alone. And there is frequently seen very striking exercise of this privilege, as when, in hostility to the defendant, which ill comports with the judicial office. But the loudest complaints that at present are made, are of the selection of jurors (which belongs to the prefect alone), and the restriction of the right of challenging. The prefect draws up a list of sixty jurors, of which the president of the assizes strikes out twenty; the defendant and the attorney-general, each, can strike out twelve, and the rest constitute the jury. In this way it is possible to collect a jury consisting of enemies of the accused, and it is asserted that this is often done in the case of prosecutions for political offences. The best French jurists (Dupin, Perrug, Paillet, Ravoux, &c.) are therefore fully agreed that the French jury contributes little towards the administration of justice. Even in England, its value is very doubtful. It may seem rash to attempt to assail the general conviction, not only of the English but of the French also, and other nations that even rise, in this popular institution, the palm-tree of genuine civil freedom, and place entire confidence in their trial by jury. But it is only the cases of political prosecutions, or those in which the accused have been pursued by the revenge of the government, which give to the trial by jury its reputation; there is still another question, not only whether the jury always merits this reputation, but whether the desired advantage cannot be attained equally well, and even better, by a proper organization of the judicial office. But to return to what we were saying on the value of the jury: This body in England was not able to prevent the infamous trial of Jeffreys (chief justice under James II.) from giving his private hatred, nor has the French jury been

able to oppose any obstacles of importance to such an abuse of the judicial office. Algernon Sidney and Lord Russell were condemned to death by the verdict of a jury. For common criminal cases, there can hardly be any more uncertain, fluctuating form of decision than the trial by jurors, who, without imparting to others the grounds of their verdict, or even settling any just grounds in their own minds, decide on the honour, freedom and life of their fellow citizens. In the first place, the actual existence of a crime need not be proved according to fixed rules. Suppose the case of a man being missed, or of a corpse being found—the jury are persuaded that a murder must have been committed, and pronounce some suspected person guilty, when it is possible that the missing man still lives, or that the dead man perished without personal violence. Some years since, David Evans was executed in London as the murderer of his wife, because an apothecary, who had never practised as a surgeon, maintained that the woman died in consequence of a wound on her head, while a surgeon in actual practice asserted, on the contrary, that the wound had nothing to do with her death, and that this was occasioned by an inflammation of the bowels. (*Morning Chronicle*, 1818, February 24.) In the second place, the jury give their verdict on the slightest and most remote evidence, when the offence in question is an injury to property, a theft, robbery, fraud, or the like. The instances in which the innocence of persons condemned for such offences subsequently appears are therefore constantly increasing, and the explanation of this circumstance is to be found in the character of the jury, who are taken mostly from men of business in the middle classes, who feel more hostility to a thief or a swindler than to a murderer. The jury act, in fact, the part of legislators: when the penalty imposed by the law appears to them too severe,—as, for instance, the punishment of death for stealing property to the amount of forty shillings,—they settle at their own pleasure the degree of the offence, so as to avoid the strictness of the law; and it has happened that a jury has declared a man who had stolen ten guineas (210 shillings) guilty of theft to the amount of thirty-nine shillings. The personal feelings of the jury towards the accused, and the light in which they regard the offence, often determine what the verdict will be, before the trial is begun. It has been proposed, in Germany, to make juries give their reasons for their verdicts; but this only proves that the nature of this institution is not understood. An exhibition of their reasons comports as little with their nature as a further examination by a different tribunal. The verdict of the jury comes like a decree of destiny, without being capable of justification, examination, or amendment; for the whole of the decision rests on things which cannot be a second time exhibited in exactly the same modifications—the deportment of the accused and the witnesses, the individual and momentary dispositions of the jurors. Even in England, doubts of the importance of the trial by jury are by degrees excited, and there is an approximation to the fundamental views of the German criminal process, which aims at exciting the moral feelings of the criminal by solitude and examination, and producing a confession, which makes the accused his own judge. No criminal is so hardened as never to experience a state of mind when the burden of conscience is too heavy for him, and he desires to reconcile himself to the law and his inward judge. To produce this effect is the aim of the criminal judges of Germany; and certainly it is at least as conformable to the high dignity of the administration of justice as the trial by jury. The abridgment of the length of the process,

and the publicity of the administration of penal justice, are different things, and, though they are commonly united with the trial by jury, are advantages which may be embodied with any other system.

The views suggested in the previous part of this article, written, as has been already observed, by a civilian unaccustomed to the practical operation of the trial by jury, deserve the consideration of minds accustomed to a different course of jurisprudence, not only from their theoretical acuteness, but from their development of supposed practical defects in the trial by jury. It seems fit, therefore, to give another exposition of this subject, which is maintained by persons educated under the common law, and to suggest some of the reasons why it is deemed the bulwark of public liberty, and the best safeguard of private rights under our forms of free government. The remaining part of this article is to be considered as independent of the foregoing; not so much as presenting a counter view, but as presenting the true grounds on which the institution was established, and is still dear to the free inhabitants of Britain and America.

I. *The Origin of the Trial by Jury.* It has been traced back by antiquarians to a very early period in British history, and seems, indeed, in some form, if not coeval with the origin of the civil government in England, at least to have been used time out of mind in that kingdom. It is lost among the early Saxon colonies; and probably was derived from the mode of administering justice by the peers of the litigant parties in the feudal institutions of Italy, France, and Germany. Mr Justice Blackstone (3 *Comm.* 349, 350) considers that this tribunal was universally established among all the northern nations, and so interwoven with their very constitution, that the earliest accounts of the one give us also some traces of the other. Mr Wynne (*Eunomus, Diag.* 3, s. 50) seems to entertain a different opinion, and, after stating that its origin is obscure (*caput inter nubila condit*), he asserts, that it is the noblest form of policy that was ever invented on earth, and comes nearest the impartiality of heaven. But, whatever may be the origin of the trial, it is of very high antiquity. And *Magna Charta* (ch. 29) referred to it as an existing institution, and provided that no person should be hurt, either in his person or property, unless by the judgment of his peers or the laws of the realm (*nisi per legale iudicium parium suorum vel per legem terra*).

II. *The different Kinds of Juries.* Juries are of two sorts, viz. grand juries and petty juries. The former may consist of any number more than twelve, and less than twenty-four persons. The office of the grand jury is to accuse persons who are supposed to be guilty of an offence. It may, therefore, properly be called the *jury of accusation*. The petty or petit jury consists of twelve persons only, and may properly be called the *jury of trials*, both in civil and criminal cases.

III. We shall first consider the organization, functions, and proceedings of the grand jury. The mode of accusation is by a written statement in solemn form, describing the offence, with all the proper accompaniments of time and circumstances, and certainty of act and person, which is called an *indictment*, or by a mode less formal (which is usually the spontaneous act of the grand jury), called a *presentment*, and which is afterwards put into solemn form by some proper officer. No indictment or presentment can be made except by the concurrence of at least twelve of the jurors. The grand jury may accuse upon their own knowledge; but it is generally done upon the testimony of witnesses under oath, and other evidence produced and heard before

them.\* The proceedings of the grand jury are, in the first instance, at the instigation of the government or other prosecutor, and are *ex parte*, and in secret deliberation. The accused has no knowledge of, nor right to interfere with, their proceedings. If they find the accusation true (which is usually drawn up in form by the public prosecutor), they write upon the indictment the words "a true bill," which is signed by the foreman, or chief of the grand jury, and is presented to the court publicly, and in the presence of all the jurors. If the indictment is not proved to the satisfaction of the grand jury, the word "*ignoramus*" (we are ignorant), or "not a true bill," or "not found," is written on it by the grand jury, or by their foreman, and it is then, in common parlance, said to be *ignored*, and the accusation is dismissed, as unfounded. When the grand jury return an indictment as a true bill (*billa vera*), the indictment is said to be *found*, and the party stands indicted, and may be required to be put upon his trial. When the indictment is not found, or is declared to be not true, the accused, if he is in custody, or has been in any way required to appear at the court, and answer to any accusation against him, is entitled to be discharged, or dismissed from any further inquiry or attendance before the court. Every public offence may be properly the subject of an indictment, and taken cognizance of by the grand jury of the county within which it is committed. But there is another mode of proceeding at the common law, at the suit of the king, called an *information*, which is similar to an indictment, except that it is not found by the grand jury, and is filed, *ex officio*, by the proper officer of the government. An information cannot be filed except in cases of mere misdemeanors, or offences not capital; for, whenever any capital offence is charged against a party, he cannot be put upon his trial unless the accusation be made by the grand jury by indictment.

IV. *The Organization of the Grand Jury.* The functions being such as we have stated, it is obvious that the duties require great care in the selection of the persons who are to serve as grand jurors. A precept, commonly called a *venire facias*, issues to the sheriff of every county, some time before any court of criminal jurisdiction is held therein, requiring him to summon twenty-four good and lawful men of his county, to attend the court, to inquire into, and present all offences committed within the body of the county. At the common law, these grand jurors are required to be freeholders of the county, and in England, where the sheriff makes the selection, they are usually gentlemen of the first respectability in the county. In the United States of America, different modes prevail in different states in the selection of grand jurors. In some, the grand jurors are chosen, as in England, by the sheriffs; in others, as in the New England States, the grand jurors are drawn by the town officers, from boxes containing the names of all the persons qualified to serve, from time to time, and in such numbers as are required; and the names so drawn are returned to the sheriff, and by him to the court. But, in whatever way the grand jurors are selected, their names are returned on a piece of parch-

ment or paper, by the sheriff, which is called a *panel*, and as many of them as appear in court are sworn as the grand jury, not exceeding twenty-three, so that twelve may constitute a majority. Their oath is, in substance, that they will diligently inquire and true presentment make of all offences committed within the county; that the government's counsel, that of their fellows, and their own, they will keep secret; that they will present no man for envy or malice; neither will they leave any one unrepresented from fear, favour, affection, or hope of reward; but that they will present things truly as they come to their knowledge, according to their best understanding. Usually, the presiding judge of the court instructs them in the matters which are within their jurisdiction, by delivering to them a charge, containing a summary of the offences and other business which may come before them. They then retire to their room, and sit, as has been said, in secret, hearing evidence in favour of the prosecution only, as the main question before them is, whether the party accused ought to be put upon his trial to answer the accusation. But they are always bound to act upon legal evidence, and are instructed that they ought not to find an indictment unless upon their oaths they are persuaded, so far as the evidence goes, that the accusation is true. It has been already stated, that the grand jury is to inquire only into crimes committed in the county for which they sit. And this is regularly true at the common law, for no man was bound to answer for any crime but before his peers in the county and neighbourhood where it was committed. But, by sundry statutes, both in England and America, some offences, not committed within a county, have, to prevent a defect of justice, been made cognizable therein. To enumerate these offences would occupy too large a space. There are proper powers vested in the courts to compel the attendance of grand jurors; and if any are returned who are not qualified, they may be excluded from the panel; and if an indictment be found by persons not qualified, the accused may except to it on this account. These careful has the law been, in the original selection of grand jurors, who are supposed, and indeed required, to be men of integrity, impartiality and intelligence, and above all just objection. And thus a body of men, brought together for the occasion, and for that only, are placed between the government and the citizen, as a shield against oppression and injury, and to afford a reasonable protection to him, if he be not justly suspected of a crime.

V. *As to Petty or Petit Juries, or, as they are sometimes called, Traverse Juries.* These consist, as has been already said, of twelve persons, and no more, for the trial of all criminal offences, and of no issues of fact in civil cases at the common law. There are some peculiar modes of trial by jury in England, where a larger number than twelve is required, which may be called the *extraordinary trial* by jury; as, for instance, a grand assize for the trial of issues in writs of right, which consists of four knights and twelve other persons; and the jury of attain, to convict a former jury of a corrupt verdict, which consists of twenty-four jurors. But these modes of trial are, at present, wholly disused in America; and, in England, that of a jury of attain has fallen into neglect, since the general use of the remedy of moving for a new trial, where the verdict is unsatisfactory. And first, as to the trial by jury in civil cases. This is generally confined to issues of fact in proceedings at common law, as contra-distinguished from proceedings in equity and admiralty. When, then, the parties have, in their written pleadings, or allegations, come to a fact which is denied on one side, and affirmed on the other, in a regular mode, the cause is said to

\* There are no grand juries in Scotland, except in cases of high treason, where the law is similar to that of England. In all other criminal trials, in Scotland, a number of jury-men, not exceeding forty-five, is cited. Of this number fifteen are chosen by the judge to sit upon each trial, the prisoner being allowed to object to any of them upon good grounds. It is not necessary that the jury be unanimous, as in England, in their verdict a majority being considered sufficient. Clergymen, surgeons, and butchers, are exempted from the office of jurymen. See the article Scotland, section Law.

be at issue, and the fact in controversy is to be ascertained by a jury. For this purpose, in England, a precept issues to the sheriff of the proper county, requiring him to select and summon to the court at which the trial is to be had, a suitable number of jurors, for the trial of the cause; and he accordingly makes return of the names of the jurors, on a piece of parchment or paper (thence, as before stated, called a *panel*), who are compellable to attend at the time and place appointed. If the sheriff have any interest in the case, or is not impartial, or is related to the parties, the jurors are selected by some other proper officer, and usually by the coroner of the county. The qualifications of petty jurors do not differ, generally, from those required as to grand jurors, their duties being equally important, and requiring equal intelligence. When the cause is called for trial, if all the jurors do not appear, or any of them are justly objected to and set aside (of which we shall speak hereafter), the deficiency may be supplied from among the by-standers, having suitable qualifications, which is called taking jurors *de talibus circumstantibus*, from which circumstance the persons thus selected are denominated *talesmen*. The jury, being thus full, and above objection, are sworn (severally or together, according to the local usage in each state) well and truly to try the issue between the parties, and a true verdict to give "according to the evidence" (or "according to the law and the evidence given them," by the local usage of some states). In some cases, special juries are allowed to be selected, in a particular mode, for the purpose of trying particular causes; in other cases, the trials are by a jury chosen in the ordinary manner, and thence called a *common jury*. But these distinctions are unknown in some of the states of America, though they are very important in the practice in England. After the jury is sworn, the cause is then tried in open court, the evidence is then offered, and the witnesses publicly sworn and examined in the presence of the judges, the counsel of each side, the jury, and all other persons in attendance. The question, whether any evidence is competent to be given to the jury, is, if any objection is made, first decided by the court. If rejected, it is never heard by the jury; if admitted, it is then read, or, if given by a witness, he is then examined before the jury. The party who calls a witness first examines him, and he is then liable to be cross-examined by the other side; and if any question is asked which either party deems improper, the opinion of the court is taken on it before the witness is allowed to give his answer. So, also, it is, in respect to any written evidence or document offered at the trial. And if either party requests it, the judge who presides at the trial makes a note, in writing, of the objection, so that the party may avail himself of it afterwards, upon a motion for a new trial, or by a writ of error, in a suitable manner. Before the evidence is offered, the counsel for the party who opens the cause, on each side makes a short introduction, stating the case, the points in controversy, and the facts which he expects to prove, so that the jury may more clearly understand the bearing of the evidence, as it is produced. After all the evidence is gone through, the counsel on each side argue the case to the jury, at large, commenting upon every part of it, and each insisting upon a verdict in his favour. If any questions of law arise (as in most instances they do), the judge is requested, and is bound, publicly to state his opinion on all the points of law applicable to it. This he ordinarily does in summing up the case, after the arguments of the counsel are over; but he may do it before, if he chooses. When the arguments are finished, the presiding judge, in England, and of most of the states in America, proceeds to

address the jury, stating to them the questions, recapitulating the evidence, and commenting on it in such a manner as he deems correct, for the purpose of enabling the jury to understand it well, and to apply the law properly to it. In these addresses, he often freely expresses his opinion as to the weight of evidence, the sufficiency of the proofs, the force of particular objections, and the comments of the counsel. But, it being a principle of law, that the jury is to respond as to matters of fact, and the judges as to matters of law (*ad questiones facti respondent juratores, ad questiones legis respondent judices*), it is always understood, that these comments on matters of fact are not binding on the jury, and that they are given solely with a view of enabling the jury to exercise their functions more perfectly, and that the jury are at liberty to disregard them if they please. But, generally speaking, they do receive great weight from the jury, who naturally place confidence in the judges, from their talents, experience, and impartiality; and therefore, unless the judge obviously exhibits some improprieties, or betrays some unjustifiable feeling, they consider him as a friend, aiding and assisting them in their duty; and, his addresses being always in public, and open to the criticism of the public, as well as of the profession, it rarely occurs that his conduct is deemed exceptionable. Still the jury have a right to form, and do form an independent judgment upon matters of fact; and their judgment is often conclusive. After the judge has finished his summary, the jury withdraw into a private room, where they are kept together for the purpose of deliberation, until they have all agreed in a verdict (*verdictum*) upon the point in controversy. They are not permitted to have any intercourse with any other persons, and are allowed, during their continuance in secret session, to have only such food and other necessities as are indispensable. Indeed, by the old law, they were to be kept without meat, drink, fire or candle, until they were agreed, unless by permission of the court, which soon, however, became almost a matter of course. When they are agreed, they come into open court, and their names being called, they deliver in their verdict, which is recorded by the proper officer, who then reads it aloud to the jury, and asks them if they agree to it as recorded, to which they publicly assent. If either party doubts it, the jurymen are severally asked if they agree, which is called *polling* the jury. Sometimes when the facts are very complicated, or involve questions of law of great difficulty, the jury instead of finding a general verdict, that the issue of fact is for the plaintiff or for the defendant, state all the facts at large, and ask the court to decide upon those facts, whether the issue ought to be found for the plaintiff or for the defendant. This is called a special verdict. It rarely occurs in criminal cases, and is not very common in civil cases. But the jury are never obliged to find a special verdict, and may, in all cases, give a general verdict, if they choose. If the jury, after being kept together a considerable time, cannot agree, they are usually brought into court by the proper officer, and the court, if their difficulty is about any matter of law, often makes additional explanations. But if, after every reasonable effort, the jury continue to disagree, they are discharged by the court, and the cause must then be tried anew. In criminal cases, and especially in capital cases, the court with great reluctance allow the discharge of a jury, after the cause is once committed to them.

Next, as to the trial by jury in *criminal cases*. Here the qualifications of jurors do not differ from those required in civil cases. But the law, with a view to prevent the undue influence of the govern-

ment in the selection of jurors, and the undue prejudices arising from public opinion, has thrown additional guards round the party accused. He is not only entitled to be tried by good and lawful men, of the neighbourhood where the crime is alleged to have been committed, but to be confronted with the witnesses, and to have, in capital cases, some privileges, which are not allowed either in civil cases or in offences of a subordinate character. And, in the first place, the right of challenge, which, though it exists for many purposes in civil trials, is of far more consequence and extent in criminal trials. A challenge is, properly speaking, an objection or exception to a juror, or to the whole jury, as incompetent to sit in a trial. It is of two sorts: the first is a challenge to the array, or an exception to the whole panel or list of jurors, as they are arrayed or set in order by the sheriff in his return. And it may be taken on account of the partiality of the sheriff, when he selects the jury, or of some default, omission, or illegality of himself or of some other officer or functionary concerned in arraying or returning the panel. This challenge may be either for a principal cause or to the favour, the former of which is founded upon positive proof or presumption of impropriety; the latter is founded upon less strong presumption or suspicion and therefore properly to be inquired into, or to be decided by the sound discretion of the triers. Secondly, the other sort of challenge (which also may be for a principal cause or to the favour) is a challenge to the polls, that is an exception to particular jurors, answering in some degree to the *recusatio judicis* of the civil and canon law. Challenges to the polls, at common law, have been reduced to four sorts:—1. Challenge *propter honorem respectum*, or in respect to nobility; as, if a lord or peer of the realm in England be empaneled on a jury, he may be challenged by either party, or may challenge himself. 2. Challenge *propter defectum*, or for want of proper qualifications; as if a person be an alien or a slave; or in cases where he is required to be a freeholder, if he is not such; or is not of a suitable age, as a minor; or is a female, for females are not allowed to be jurors; or is convicted of an infamous crime, or is otherwise disqualified. 3. Challenge *propter affectum*, for suspicion of bias or partiality. This may be a principal challenge, as has been already stated, when there is pregnant proof or presumption of partiality or of malice, as that a juror is of kindred to either party (at the common law, in the ninth degree); that he has already prejudged the cause, as an arbitrator; that he has an interest in the cause; that he has taken money for his verdict; that he has formerly, as a juror, tried the same cause; and that he is the servant, master, attorney, or counsel of one of the parties. A challenge to the polls for favour (which supposes a doubt of impartiality) is where the party has no principal cause of challenge, but has suspicion of favour, and offers circumstances in support of such suspicion. In such a case, the validity of the objection is, by the common law, left to the determination of triers, whose office it is to decide whether the juror who is objected to is favourable or unfavourable, or, rather, whether he stand indifferent between the parties. The triers, in case the first man called as a juror is challenged, are two indifferent persons, named by the court; and if they try one man, and find him indifferent, he is sworn, and then he and the two first triers try the next who is objected to; and when a second is found indifferent, those two who are sworn as jurors become the triers of all the others who are objected to, in lieu of the two triers first chosen. 4. Challenge *propter delictum*, or on account of some crime, of which the person called as

a juror has been guilty, and which imports a disability and discredit as a juror. This applies to cases of a capital nature, and other infamous crimes, such as treason, felony, perjury, conspiracy, and other species of the *crimen falsi*. A person called as a juror may be called to say the truth (where he is said to be interrogated *voir dire, veritatem dicere*) in respect to such causes of challenge as are not to be discredited or dishonour; but he cannot be called upon to acknowledge himself guilty of any crime, or other thing which renders him infamous. There are also the causes, strictly speaking, of challenge by the parties. But many persons are entitled to be excused from serving on juries, and, on this account, may plead the excuse for themselves, though the parties may not take the exception. Among these are magistrates, aged persons, and persons holding particular offices, and others having special exemptions. The challenges above mentioned equally apply to civil and criminal cases. But in favour of life, in capital trials, the accused is intitled the privilege of challenging a certain number of persons, called as jurors, without assigning any cause; and this privilege is thence called the right of *peremptory challenge*. This is a provision founded on great humanity and tenderness towards persons capably accused. The reasons commonly assigned for it are, 1. that every person is liable to strong dislikes and prejudices, in respect to particular persons, merely from their appearance, manners, and gestures, although they are strangers to him, and that even a caprice or feeling of this kind may, in the course of the trial, embarrass the party in his defence; 2. that upon a challenge for cause shown, the reason may prove insufficient, and, if the party had no right of peremptory challenge, he might be tried by a jury who, from the very circumstance of being objected to, might conceive a prejudice against the accused. On these accounts, he is at liberty to challenge the juror peremptorily, after he has, for an insufficient reason, challenged him for cause; and, as the object of all trials is to allow a fair and full defence, he is accused ought, at least, to have his wishes considered so far as to exclude those whom he distrusts in the first instance. But as it is obvious that the right of peremptory challenge, if not limited by some known boundary, might for ever prevent a trial, the law has fixed a definite number, to which the party is confined. The common law fixed this number at thirty-five, or one short of three full juries; and that still remains the rule in all trials for treason. But in other capital offences, the right is now generally restrained by statute, to twenty, both in England and America. If a person attempts to challenge beyond this number, his challenge is disregarded. If, by means of peremptory or other challenges, a sufficient number of jurors are not found, talesmen are appointed, as in civil cases. If several persons are tried at the same time, upon one indictment, each one is entitled to the full number of challenges, and one may challenge a juror not objected to by the others, and be made to be excluded altogether; for every jurymen must be above any objection by any of the persons tried. We have thus far treated of challenges by the party accused. The government has, strictly, no right to challenge, except for cause shown; but for cause shown the government may either challenge the array, or the polls, in the same manner as a private person. However, it is usual, at least in England, if a juror is objected to by the government, not to call upon the government to show cause, but the panel is gone through, and then, if sufficient jurors are not found and sworn, the cause of the challenge may be inquired into; for, if there is a fault without the persons objected to by the government.

there is no strong reason to insist upon their being sworn, although no good cause has been shown.

There are some other provisions favourable to prisoners accused of capital offences, and especially of political offences, which deserve notice. In England, in cases of treason, the prisoner is entitled to a copy of the indictment five days before his arraignment for trial, and a copy of the panel of jurors who are summoned, and their professions and places of abode, ten days before his trial, and a list of the names of the witnesses to be produced against him, the like length of time before the trial. He is also entitled, at the expense of the government, to have witnesses summoned in his behalf, to establish his defence, and to have counsel assigned to assist him in his defence. In America, in cases of treason, similar provisions in substance exist, with a difference only in respect to the length of time allowed for the copy of the indictment, and lists of jurors and witnesses. And in many of the states, an equally humane provision exists in respect to all other capital offences. By the laws of the United States of America, the prisoner is entitled to have counsel assigned to him, and to have his witnesses summoned at the expense of the government, in all capital cases. In cases of treason, a copy of the indictment is required to be delivered three days before the arraignment, and also a copy of the list of jurors and witnesses summoned by the government, three days before his trial. In other capital cases, the time is two days, instead of three. The right to employ counsel in defence, is also secured to all persons accused of any crimes in the United States. But in England, it is confined to cases of treason, and to mere misdemeanours. In capital cases, not of treason, counsel are not permitted to be employed in England, except in arguing questions of law.\* The quaint and unsatisfactory reason given for this exclusion is, that the judges are counsel for the prisoner,—a reason which, if good in any, is sufficient in all cases. But there is more of speciousness than of truth in the remark; for, though the judges ought to take care that the prisoner has a fair and impartial trial, it is impossible that they can act as counsel for the prisoner exclusively; and the importance of counsel, exclusively for the prisoner, is admitted in all cases of treason. Why not equally so in other capital cases?

Such is a very general outline of the trial by jury under the common law. It is deemed of immense value in Britain, and among the dearest rights of the people. In America, it is quite as dear, and is deemed of such high importance, that the right to a trial by jury, in all criminal cases, is secured by the constitution of every state in the Union, and is also provided for, in all civil cases at common law, where the amount in controversy is of any considerable value. This strong attachment to the trial by jury, both in Britain and America, after the experience of it for centuries, furnishes no small argument in favour of its efficacy as a security of right, and a redress of wrongs. It is perpetually spoken of as the palladium of our public rights and liberties; and in all the various fluctuations of public opinion, it has remained untouched and unsuspected. It is not surprising that those, who know it only in theory, or who at present see the administration of its powers and duties in a very imperfect state in the civil law countries, or who are accustomed to a jurisprudence foreign to its principles, should entertain doubts of its advantages, and should feel a deep sense of its

defects. The first part of this article shows how difficult it has been to transfer to France the trial by jury, and to administer it with the same beneficial effects as in Britain. The errors in France may have resulted, in part, from the imperfect knowledge of the courts, as well as of the juries, from the novelty of this mode of trial, and their want of experience in the management of it. Perhaps, too, there may be something in the other institutions of France, or in the temperament and character of the people, which may disturb its proper operation.

It may be useful for us, before concluding this article, to review some of the grounds on which the trial by jury has been hitherto vindicated, and to glance at some of the defects which it is supposed to involve, as well as at some of the objections to which it is supposed to be liable—*Fas est et ab hoste doceri*. And, in the first place, it is not necessary to contend that, as an instrument of public or private justice, it is an institution absolutely perfect; that it is incapable of abuse; or that it never occasions error. That would be to require of it what belongs to no human institution whatsoever. Every work of man is, by his very nature, imperfect. Every form of government involves some inconveniences, and errors, and abuses. Every effort to administer justice must necessarily fall short of perfect correctness, from defects of evidence, from the infirmity of judges, from the wrong biases of human opinion, from errors in reasoning, from ignorance, and passion, and prejudice, independently of all intentional wrong, or corrupt motives, or malice, or dishonesty, or deliberate baseness. The only question is, what, on the whole, is the best means of administering justice, taking human nature as it is, and human infirmity as it must ever operate. If crimes are to be tried and punished, if rights are to be enforced and wrongs redressed by judicial tribunals, what is the best structure of the institution for the purpose of trial and decision? There seems to be but a narrow circle of means, out of which the choice is to be made. Shall the tribunal be composed of executive officers of the government, or of judges appointed by the government for each case, or of judges holding their office at the pleasure of the government? Or shall the tribunal be composed of judges holding their offices permanently, and independently of the government? Or shall the tribunal be composed of jurors chosen at large, *pro hac vice*, or chosen permanently for that duty, without any previous qualifications of legal experience, learning or superior ability? And if so, by whom, and in what manner, shall they be chosen? Or shall the tribunal be of a mixed character, composed of judges learned in the law, permanent in rank and station, and of jurors selected for the occasion in an impartial manner, and the trial be had before the judges expounding the law, and the juries deciding the facts? In cases of crimes, the object is to protect the innocent and to punish the guilty. Where does the danger chiefly arise? In political accusations, the government not only is a party, but has a strong motive to produce conviction. In other cases, it may not have so strong a motive, but it may be subject to influences of an equally fatal character. If the king or other executive, or officers selected by him for that purpose, *pro hac vice*, are to decide upon the guilt or innocence of the party, according to their own discretion and such proofs as are satisfactory to themselves, there is no security whatsoever against unjust convictions. The decision will be arbitrary, and according to the will of the prince or his favourites, or according to state policy, or perhaps public prejudice, actuated by strong resentment. If the trial be by judges solely appointed by the government, and holding their offices permanently, there may be

\* The case is different in Scotland, counsel there, in all criminal cases, being not only allowed but required, and, if the prisoner be poor, furnished at the public expense.

dangers arising from other and different sources, from their political opinions, from their state interests, from their irresponsibility to public opinion, and from influences of character and profession, which insensibly warp the judgment. If the trial be by permanent jurors, there will be still greater dangers from their want of the proper learning, and general weight of character, added to the other objections. So that any of the proposed substitutes does not furnish more safety or certainty, in the administration of criminal justice, than that of a trial by jury.

On the other hand, the trial by jury, as known to the common law, affords some checks upon arbitrary power, and enlists many just feelings and reasonable guards against oppression. 1. The jurors are selected from the mass of intelligent citizens, of suitable qualifications, and of the same rank, and having the same general interests, as the accused. They are not permanently employed, and have no common connexion with each other, and no habits of fixed co-operation. They are, or may be, strangers to each other, and to the accused, until the moment when they are empaneled. They are subject to no reasonable exception, either in point of character or influence, for that would exclude them, at the will of the accused. They are subject to the same laws, and liable to the same prosecution, as the party on trial, and therefore have a natural tendency to sympathize with him. 2. The trial is had in open court, before judges who hold their offices permanently, and who are bound to administer the law, and to give their opinions publicly to the jury. From the moment that they are empaneled, they are excluded from all intercourse with every person except what takes place in open court; and their subsequent deliberations are private and secret. 3. They are under oath to decide the case upon the evidence given in open court. No testimony can be heard by them, except what is admitted and delivered in open court; so that the court, the counsel, and the by-standers, have a perfect knowledge of every part of it. Thus the whole public become the ultimate judges of the sincerity and justice of their verdict. 4. If they find a verdict against the party, and there has been any error of law or fact, or any misconduct in the jury, the court will grant a new trial; but if they acquit him, there can be no new trial, for the law will not allow a man to be twice put on trial for the same offence, and thus his life, liberty, or limb be put in jeopardy. Here we see the humanity of the common law, which leans in favour of the accused, and disables the government from practising oppression upon any citizen, by successive vindictive prosecutions. 5. Again, if the evidence is doubtful, the party is entitled to an acquittal, and the court will so direct the jury; for the common law will not tolerate that any man should be punished, unless there be satisfactory proofs of guilt to the minds of twelve of his peers or equals. 6. It has been said that the facts are often complicated, and the guilt is compounded partly of facts and partly of law. This is true; but here again the wisdom of the common law has provided that the judges shall state to the jury what the law is, as applicable to the various postures of the facts, as they may find them. They are also generally assisted by the arguments of the counsel on each side, in arranging and comparing the facts; and the judge, in his summing up of the evidence, brings the whole in review, and points out to them the bearings of every part, and strips off the false glosses, if any, which have been made by counsel. But he still leaves them to decide upon it according to their own conscientious belief of it. 7. It is said that the arguments of counsel may deceive them, and blind them to the truth. But the answer is, that they have an equal oppor-

tunity to hear the opposite side, and that, generally the judges assist them, when there is any attempt to misstate the evidence, by referring to their own notes of it, as given in open court. And from long habits, and experience in human life, jurymen learn to disregard the mere efforts of eloquence, and, under a sense of their religious and social obligations, consult the real truth and justice of the case. Would there be more security if no counsel were allowed? No person will say so. 8. It is also said that the judges may have an undue influence with the jury. This is certainly possible, and has actually occurred in corrupt times. In the case of chief-justice Jeffreys, referred to in the preceding part of the article, it should be remembered that he held his office during the pleasure of the crown, and not, as the judges of England now hold, during good behaviour, or life. He was a devoted partisan of the crown, and he became infamous by his corrupt administration of the law. But it should be considered, that the jury could scarcely have been free from improper biases of some sort, otherwise they could not have found a verdict against the accused. In our day, and, indeed, at any time since the arbitrary times of King James II. and the revolution of 1688, such conduct as a judge would be sure to meet with universal reprobation, and would generally produce an acquittal of the prisoner, and a public impeachment of the judge. Nay, it is well known, that such is the jealousy of juries in this particular, that any undue interference or solicitude for conviction, exhibited on the part of a judge, would destroy his influence, and produce an opposite verdict. It is his supposed impartiality that gives weight to his opinion; and the jury know that they have a right to disregard it, if they please. 9. It is said, that juries may be influenced by improper motives, and sometimes disregard the law, and give a false verdict. This is possible, and, indeed, has probably sometimes happened. But the occasions are rare; and where there is a suspicion of that sort, it always injures the character of the jurymen, and subjects them to public scorn and censure. Generally, juries are scrupulous in respecting the law, because it is the only protection of their own rights. Where the law is very harsh, and the punishment is disproportioned to the offence, they have sometimes exhibited a repugnancy to convict; but they rarely have acquitted the party, unless there were circumstances of great doubt, or of great mitigation; and if their conduct, in such cases, is not strictly justifiable, it is generally not such as produces any reproach, either from the court or the public. These occasions, however, are rare, and constitute exceptions of a great moment in the general administration of justice. 10. It is not true, as is sometimes supposed, that juries are ready to convict on slight proofs, or insufficient evidence. Our law declares, on the contrary, that in such cases they ought to acquit the party; and it is always laid down to the jury by the court. Indeed, the judges, in this respect, always act as counsel for the prisoner, and give their advice to the jury, in respect to every reasonable doubt as to the evidence. There are so many checks upon jurymen, in cases of this sort, that it can scarcely happen, that an unjust conviction, at least by the improper bias of the jury, can take place. If there be any error, it is usually on the side of mercy. 11. It is objected, that the jury sometimes find the party guilty of a part, and not of the whole offence, as of manslaughter when he is accused of murder. Certainly the jury do so; and for the best reason, that the law requires it. A jury ought not to find a man guilty of the whole of a charge, unless it is wholly proved. If what is proved amounts to a crime of the same nature, but of inferior enormity, or more mitigated than what is

charged, they find their verdict according to the proof, and the court inflict only the moderated punishment. And any other course would be flagrant injustice. But a jury cannot, upon a trial for one offence, find a man guilty of another offence, not of the nature of the one charged; for instance, upon a charge of murder, they cannot find him guilty of forgery; but if he is charged with stealing two watches, they may find him guilty of stealing only one. 12. It is also objected, that juries often favour criminals. But this is not generally true, except to the extent that the law favours them. There may be cases of a popular cast, or of an odious nature, where juries have occasionally shown improper biases for the accused; but this objection applies to all tribunals, and is founded on human infirmity generally. Juries do not, even in cases of this sort, often depart from their duty; and the exceptions are so few, that they are seldom felt or urged in free governments. 13. But an objection the most pressed by those who are not practically acquainted with the trial by jury, is, that unanimity is required in pronouncing a verdict of acquittal or condemnation. It is true, that no verdict can be received in England which has not the assent of all the twelve jurors; and there are no means of compelling an assent; and yet, practically speaking, few cases of disagreement occur, except where there is a solid foundation for real doubts and difficulties. Unanimity is more common than, at first view, might be suspected. In the first place, the jury reason with each other upon all doubtful points, and if they at first differ, the differences are often removed by further discussion. Pride of opinion is not enlisted on either side, and sometimes each recedes from the first limits of his own opinion. In the next place, the differences of opinion are more often upon inferences and conclusions from known facts than upon the facts themselves; and more often upon doubts as to the proper application of the law to those facts; and still more often upon mere collateral questions, where there is no common standard of measure, as in assessing damages. In criminal cases, fewer difficulties ordinarily arise than in civil cases, because doubts weigh favourably for the accused, and often produce an acquittal. But, after all, there is not probably one in twenty cases, tried by a jury, in which there is a final disagreement; and it is by no means sure, that a decision could be had more just or fair by requiring a majority, or any other number, than by requiring unanimity. The jurors might then be equally divided, or the struggles of the minority to prevent a verdict might be equally violent. Most trials give rise to differences on several points; and, in such cases, the unanimity of a majority, in a general verdict, must be produced in the same manner as unanimity in the whole jury. But the best answer to the objection is, that experience is in favour of requiring unanimity of the whole jury. No practical evil has, as yet, been felt from the rule. And it is no small recommendation of it, that it gives a satisfaction and confidence to the public mind, in England and America, that the decision of a mere majority could scarcely ever give. If unanimity is less easily obtained in France, that proves nothing as to the value of the principle elsewhere. The failure may be from the novelty of the trial in France, or from the habits and character of the people, or from the imperfect comprehension of the duties of the judges and the jury.

Most of the remarks above made refer especially to juries of trial in criminal cases; but they are, in a great degree, applicable to civil cases also. It remains only to add, that the other preliminary guards, interposed by the common law in criminal cases, are of inestimable value to every citizen. He cannot be accused, nor be brought to trial, unless upon an

indictment found by a grand jury. He is thus saved from prosecutions founded in malice, hatred, political opposition, personal feeling, and popular prejudice. The government cannot touch him; the people cannot make him the victim of their jealousy or suspicion. A grand jury of incorruptible and impartial men, who are his equals, must first accuse him, upon the hearing of legal proofs and sworn witnesses, before he can be called to answer for any offence. Twelve men, good and true, (*probi et legales homines*), must concur in the indictment; and twelve more must concur upon his trial, in asserting his guilt, before he can be punished. When his guilt is ascertained, the punishment rests, not in the discretion of the king, or of the government, or any mere executive officer; it is to be declared by the judges, before whom he has been tried, or in the same court, according to laws previously passed, and regulating the nature and extent of the punishment. It is not too much, then, to affirm that the trial by jury is justly the boast of England and America; and we may hope that, by the goodness of Providence, it may be perpetual.

**JURY-MAST;** a temporary or occasional mast erected in a ship in the place of one that has been carried away by tempest, battle, &c. Jury-masts are sometimes erected in a new ship, to navigate her down a river, or to a neighbouring port, where her proper masts are prepared for her.

**JUS** (*Latin*) signifies 1. that which is right or conformable to law; also the obligation which the law imposes; 2. a body of laws, decrees, and usages; 3. a man's privileges, singly or collectively; 4. the place where justice is administered; 5. the power which originates from the law. Hence the word is of very frequent use in law.

*Jus divinum* is that which is ordered by a revelation, in contradistinction to that which is ordered by reason; but as the *right* must be one and the same, it is evident that the distinction exists only in the form, and not in the essence, because that which is ordered by our reason is to be referred to God, as its origin, equally with that which is decreed by revelation. A law may have both a human and a divine origin; for instance, "Thou shalt not kill." This rule may be adopted because it is ordered in the decalogue, or because it is the dictate of reason, and is established by most nations, unacquainted with the decalogue. The division, however, is rather antiquated, and the philosophical lawyer will refer all law to a common origin. See Thomasius, *De Jure Div.*

*Jus Italicum* signified the lowest degree of privileges enjoyed by cities under the Romans.

*Jus Latii*, or *jus Latinum*, denoted the privileges granted by the Romans to the inhabitants of Latium, according to the various significations of the word. (See *Latium*.) It held a rank between the *jus Italicum* and the *jus Romanum*.

*Jus Quiritium* (*civitas optima lege, optimo jure*); the fullest enjoyment of Roman citizenship, the privilege and obligations of Roman freeborn citizens, including in the flourishing times of the commonwealth, 1. public privileges—*libertas* (security of personal liberty, *militia* (participation in the service of the legions, *census* (registration on the list of property: see *Census*), *jus tribus* (the incorporation in a tribe), *jus suffragiorum* (the *jus Quiritium* in a narrower sense, the right of suffrage), *jus honorum* (participation in public honours), *jus sacrorum* (participation in religious celebrations, *sacra publica* and *privata*); 2. private privileges—*jus gentilitatis et agnationis* (the privilege of family and clan; e. g. *successio* and *tutela agnatorum*, *jus legitimi domini* (the privilege of lawful property), *jus connubiorum* (privilege of lawful marriage), *jus patrimonii* (unlimited power over the persons and property of real or

adopted children). Heineccius and others mention only two *jura Quiri.*, and, besides them, *jus civilis* or *civilis Romana*. Couradi *De Jure Quir.* a *Civitate Romana non diverso*. Helmstedt, 1742, 4to) is of a different opinion. Still different is the opinion of Cramer. (*De Jure Quiri. et Civitatis Discrimine*, Kiel, 1803, 4to.) At all events, the *jus civilis* was of a more limited character than the *jus Quiritium*. Thus newly admitted citizens received it.

JUSSIEU, ANTONY and BERNARD, DE; two brothers, born at Lyons, in the latter part of the seventeenth century, eminent as physicians and botanists.

Antony made a botanical tour, and brought from Spain a large collection of plants. After this he wrote upon subjects connected with natural history and medicine, and died in 1758, in the seventy-second year of his age, much lamented on account of his philanthropy.

Bernard, born in 1699, was appointed professor of botany in the royal botanical garden. We are indebted to him for a new edition, in two volumes, 12mo, of Tournefort's History of Plants in the Neighbourhood of Paris (*Histoire des Plantes qui naissent aux Environs de Paris*), published in 1725. Jussieu's scholars used to bring him flowers which they had mutilated or compounded with others, for the purpose of testing his knowledge, and he always recognised them immediately. Some of them having made the same experiment on Linneus, he said "God or your teacher (Jussieu) can alone answer your questions." Jussieu, after having been a long time employed upon a systematic division of the vegetable kingdom, died in 1777, aged seventy-nine. Cuvier, in a biographical memoir on Richard, calls Bernard de Jussieu "the most modest, and, perhaps, the most profound botanist of the eighteenth century, who, although he scarcely published any thing, is, nevertheless, the inspiring genius of modern botanists."

Antony Laurence Jussieu, nephew of Bernard, born at Lyons, in 1748, physician, member of the academy of sciences at Paris, and of the royal medical school, made a report, in 1804, on the results of captain Baudin's voyage to New Holland. In the anatomy of plants, he has distinguished himself by having made known the discovery of a substance enclosed in the kernel, called by him *perisperma*.

**JUSTICE OF THE PEACE.** The word *justice* is applied to judicial magistrates; as *justices* of such a court, and, in English laws, *justices of the forest*, *hundred*, *of the labourers*, &c.; and hence the appellation *justice of the peace*.—that is, a judicial magistrate intrusted with the conservation of the peace. A great part of the civil officers are, in fact, the conservators of the peace, as their duty is to prevent or punish breaches of the peace. Thus the judges, grand-jurymen, justices of the peace, mayors, and aldermen of municipal corporations, sheriffs, coroners, constables, watchmen, and all officers of the police, are instituted for the purpose of preventing, in different ways, crimes, and disturbances of the peace of the community, or for arresting, trying, and punishing the violators of the laws and good order of society. In Britain, the justice of the peace, though not high in rank, is an officer of great importance, as the first judicial proceedings are had before him in regard to arresting persons accused of grave offences; and his jurisdiction extends to trial and adjudication for small offences. In case of the commission of a crime or a breach of the peace, a complaint is made to one of these magistrates. If he is satisfied with the evidence of a commission of some offence, the cognizance of which belongs to him, either for the purpose of arresting, or for trying the party accused, he issues a warrant directed to a con-

stable, or other executive officer designated by the law for this purpose, ordering the person complained of to be brought before him, and he thereupon tries the party, if the offence be within his jurisdiction, and acquits him or awards punishment. If the offence charged be of a graver character, the adjudication upon which is not within the justice's jurisdiction, the question then is, whether the party complained of is to be imprisoned, or required to give bonds to await his trial before the tribunal having jurisdiction, or is to be discharged; and on these questions the justice decides according to his view of the law and the facts. In Britain, there are some officers, as the master of the rolls, some municipal authorities, &c., who are justices of the peace by prescription, in virtue of their other office; but, in general, the appointment is by commission; and, in Britain, when a new commission issues to justices in a certain county, this supersedes former commissions for the same county, of course. In America the office is held only by special appointment, and the tenure is different in different states, the office having been held, in one state at least, during good behaviour; but the commission is more usually for seven years, or some other specific limited period. In France, justices of the peace are in many respects different from those of Britain and America, though the national convention, in its famous decree respecting the new organisation of the judicial system (August 24, 1790), which, in its principal features, still exists, evidently contemplated a closer imitation of the British system. France, as it is well known, was then divided into departments; these into districts (at a later period called *arrondissements*), and these into cantons, in order effectually to efface the ancient division into provinces, lordships, &c. In each canton was a justice of the peace, to be elected by the citizens, with some assistants (*prud'hommes*), for two years, in lieu of the former feudal courts. His business consisted in the decision of cases where property was in dispute not above 100 livres in amount (up to fifty livres without appeal); in the settlement of disputes respecting possession and those relating to verbal injuries; in making compromises and discharging guardianships. At a later period, the jurisdiction of these officers was made to comprise the lower offences against the police regulations. The justices of the peace remained elective until the restoration, though the consular constitution of the year VIII (December, 1799) extended the term of the office to three years; and, in 1802, it was extended to ten years. According to the *Charte Constitutionnelle* of 1814, the justices of the peace were appointed by the king for life. The average number of persons within the jurisdiction of a justice of the peace is 10,000. All processes in any way complicated (above 100 francs, all disputes respecting the genuineness of documents (*inscriptions en faux*) are to be brought before the *tribunaux de première instance*, from which an appeal lies to the *cours d'appel*. The salary of a French justice of the peace is small; his authority is not to be compared with that of the justices in Britain, yet the office is of great importance to the country.—See Biret's *Recueil général et raisonné de la Jurisprudence et des Attributions des Justices de Paix de France* (2 vols., Paris, 1819).—Justices of the peace were usually established by Napoleon where he erected new governments.

JUSTIN, surnamed the Martyr; one of the earliest and most learned writers of the Christian church. He was the son of Priscus, a Greek, and was born at Flavia Neapolis, anciently called Scythia, a city at Samaria, in Palestine, towards the close of the first century. He was educated in the pagan religion, and, after studying in Egypt, became a Platonist,

until, in the year 132, he was led, by the instructions of a zealous and able Christian, to embrace the religion of the gospel. He subsequently went to Rome, in the beginning of the reign of Antoninus Pius, and drew up his first apology for the Christians, then under a severe persecution, in which he shows the cruelty and injustice of the proceedings against them. He was also equally zealous in opposing altered heretics, and particularly Marcion, against whom he wrote, and published a book. He not long after visited the East, and, at Ephesus, had a conference with Trypho, a learned Jew, to prove that Jesus was the Messiah, an account of which conference he gives in his Dialogue with Trypho. On his return to Rome, he had frequent disputes with Crescens, a Cynic philosopher, in consequence of whose calumnies, he published his second Apology, which seems to have been presented to the emperor Marcus Aurelius, in 162. Crescens preferred against him a formal charge of impiety for neglecting the pagan rites, and he was condemned to be scourged, and then beheaded, which sentence was put into execution, in 164, in the seventy-fourth or seventy-fifth year of his age. Justin Martyr is spoken of in high terms of praise by the ancient Christian writers, and was certainly a zealous and able advocate of Christianity, but mixed up too much of his early Platonism with its doctrines. The best editions of his works are those of Maran (Paris, 1742, folio), and of Oberthur (Wurtzburg, 1777, 3 vols., 8vo.)

JUSTIN; a Latin historian, who probably lived at Rome, in the second or third century. He made an epitome of the history of Trogus Pompeius, a native of Gaul, who lived in the time of Augustus, and whose works, in forty-four books, contain a history of the world, from the earliest ages to his own time. His history of Macedonia was particularly complete. To judge from the epitome (for the original is lost), there were many errors in the work, especially in the Jewish history; but this epitome, which corresponds to the original in its title and arrangement, having compressed into a brief space so much of the important matter of the old histories, has obtained a considerable reputation, and even now is often used in schools. The style is, on the whole, elegant and agreeable, but it is destitute of that noble simplicity and classical correctness which distinguish the work of a master. The best editions are those of Grævius (*Variorum*), Hearne (Oxford, 1705), Fischer (Leipsic, 1757), and Wetzel (Leignitz, 1806). See Heeren, *De Trogi P. Pontibus*, in *Comm. Soc. Gott.* xv.

JUSTINIAN I., surnamed the *Great*, nephew of Justin I., emperor of the East, celebrated as a law-giver, was born in 483, of an obscure family. He shared the fortunes of his uncle, who, from a common Thracian peasant, was raised to the imperial throne. While consul (521), he exhibited splendid games to the people. He likewise flattered the senate, and sought their favour; in consequence of which that body conferred on him the title of *nobilissimus*. His voice, infirm from age, and suffering from a wound, admitted him to a share of his power. Yet it was not till after his death, about August 1, 527, that Justinian was proclaimed emperor. He now married Theodora, whom he raised from the condition of an actress and a public prostitute to the throne of the empire. She acquired an absolute mastery over her husband. Under his reign, the parties of the circus contended with great animosity, and, under the names of the *Greens* and the *Blues*, occasioned many bloody scenes in Constantinople. The violent means which Justinian used to quell the tumult only served to increase it, and a conflagration, which broke out in consequence laid the greatest part of

Constantinople, and his own most beautiful buildings, in ashes. Justinian's own life was in peril. After the turbulence of these parties was extinguished by streams of blood, and a multitude of executions, Justinian finished the war with the Isaurians and his general, Belisarius, in 523 and 529, obtained three glorious victories over the Persians. This great general destroyed, in 534, the empire of the Vandals in Africa, and carried Gelimer, their king, a prisoner to Constantinople. Spain and Sicily were reconquered, and the Ostrogoths, who possessed Italy, were vanquished. In 536, Belisarius made his entry into Rome, and the eunuch Narses, another of Justinian's generals, in 553, put an end to the dominion of the Ostrogoths in Italy. These successes restored to the Roman empire a part of its former vast possessions. Justinian now turned his attention to the laws. He commissioned ten learned civilians to form a new code from his own laws and those of his predecessors. To this code Justinian added the *Pandects*, the *Institutes* and *Novels*. These compilations have since been called, collectively, the *body of civil law* (*corpus juris civilis*). (See *Corpus Juris*, and *Tribonianus*.) Justinian was also intent upon building new cities, and upon fortifying others, and adorning them with new edifices; but he was particularly desirous of establishing peace in religious matters. Amongst other churches, he rebuilt that of St Sophia at Constantinople, which had been burnt in the quarrel of the Greens and Blues. It is esteemed a masterpiece of architecture. The altar in it was made entirely of gold and silver, and adorned with a vast number and variety of precious stones. This church, a part of which is now standing, and is used by the Turks as a mosque, was so magnificent, that Justinian, when, on the day of its dedication, he beheld it for the first time, in its full splendour, cried out for joy, "To God alone be the glory! I have outdone thee, Solomon!" But it was his unhappy fortune, as it was that of the Jewish king, to outlive himself. Towards the end of his life, he became avaricious, without losing his love of splendour, suspicious, and cruel. He oppressed the people with taxes, and lent a willing ear to every accusation. (For his treatment of Belisarius, see *Belisarius*.) He suffered his own servants to commit the most flagrant crimes unpunished. He died in 565, in the eighty-third year of his age, after a reign of thirty-eight years. His love of the monks, of saints, and of theological questions, did not protect him from the censure of the divines, who esteemed him a heretic. Much that was great and glorious was accomplished during his reign, but he had little share in it.

JUSTITIA (*justice*); called, by the Greeks, *Astræa*, *Themis*, *Dikè*. With the Romans, the goddess was an abstract rather than a personal deity. She is frequently represented upon coins as a maiden, with a fillet or a diadem; sometimes with a sword and scales; sometimes with a cup in one hand and a sceptre in the other.

JUTLAND; a province in Denmark, bounded on all sides by the sea, except towards the south, where it is bounded by Sleswick. It is about 180 miles in length, and from seventy to ninety in breadth, and, of all the territories belonging to Denmark Proper, is the largest, and yields the greatest revenue. Square miles, 9500; population, 440,000. It is divided into four bishoprics—Aalborg, Wiborg, Aarhus and Ripen. The country is indented by bays and inlets, but has few rivers, and none large. The north coast is an immense range of sand-banks, dangerous to navigation. The country is generally low, having no mountains. On the east coast there are extensive forests of oak, fir, birch, &c.; on the

west are hardly any species of trees but alder and willow. The kind of grain most cultivated is rye, great quantities of which are exported to Norway. The pastures are extensive and rich; horses and cattle numerous. Iron, marble and limestone are found; also excellent turf. Most of the inhabitants speak Danish; the gentry also German. The religion is Lutheran. Agriculture and education are in rather a backward state. See *Denmark*.

The *Peninsula of Jutland*, anciently called *Cimbrica*, or *Chersonesus Cimbrica*, includes both the province of Jutland and the duchy of Sleswick in the south.

**JUVENAL**, DECIMUS JUNIUS JUVENALIS, a native of Aquinum, in the Volscian territory, flourished at Rome in the latter half of the first century. He studied rhetoric for his amusement, but afterwards devoted himself to poetry, especially satire. Having severely lashed the favourite pantomime Paris in his seventh satire, he was appointed by Domitian, under pretence of honour, prefect of a cohort (*præfectus cohortis*) in the most distant part of Egypt. Under Trajan, he returned to Rome, in the eighty-second year of his age. He was one of the most powerful and caustic of the Roman satirists. He wrote sixteen satires (the genuineness of the last, however, is doubtful), in which he chastises the follies and vices of his times. His style is not so elegant, nor his disposition so mild and humorous, as that of Horace, nor yet so gloomy and stern as that of Persius, and he often betrays the rhetorician. The best editions are those of Henninius (Utrecht, 1685, 4to.; Leyden, 1695, 4to.), and the latest by Ruperti (Leipzig, 1801, 2 vols.). Gifford's translation, with a preface and notes, is very valuable. Johnson's imitations of the third and tenth satires are deservedly celebrated.

**JUVENCUS**, CAIUS VETTIIUS AQUILINUS; presbyter in Spain; a Latin poet who flourished about 325 A. D., in Spain. He translated the history of Christ, chiefly after Matthew, in hexameters (*Historia evangelica*, Lib. iv.). A. R. Gebser published a critical edition of Juvencus in Jena (1827, 2 volumes), which makes, at the same time, the beginning of a *Bibliotheca Latina Poetarum veterum Christianorum*. In this edition an enumeration of all other editions is to be found. Juvencus also turned the book of

Genesis into hexameters (in Martini's *Novæ Collat. vet. Monument.* vol. iv., p. 15, seq.).

**JUVENTA** (*Juventas* with the Romans); the goddess of youth, but not to be confounded with Hebe; for she had not an individual, but only an abstract existence. She had a chapel near the capitol, and a festival established in honour of her was celebrated by the youth. She is represented upon coins holding a censer in her left hand, and with her right strewing incense upon a tripod, because the youth, when they came to consecrate the first growth of their beards, brought an offering of incense.

**JUXON**, WILLIAM, bishop of London, and subsequently archbishop of Canterbury, a prelate of distinguished mildness, learning, and piety, was born in the city of Chichester in 1582, and educated at Oxford. The law appears to have been his original destination. The friendship he contracted with his fellow collegian Laud, might have induced him to take orders. In 1621, he was made president of St John's college, Oxford, and, by the continued patronage of his friend, dean of Worcester (1627), clerk to the royal closet (1632), bishop of Hereford (1633), and that of London before the expiration of the same year. In 1635, he was appointed lord high treasurer of England. The nomination of a churchman to this dignified and responsible situation excited a strong sensation among the puritanical party, who made a ground of severe invective against the government and primate; but, on his resignation of the office, the integrity and ability with which he had discharged its various duties, were admitted on all hands. During the whole progress of the unhappy contest which followed, he maintained an unshaken fidelity to the king, whom he attended during his imprisonment in the Isle of Wight, and on the scaffold, on which occasion he received from the hand of Charles, the moment previous to his execution, his diamond George, with directions to forward it to his son. After the king's death, the parliament threw him into confinement for contumacy in refusing to disclose the particulars of his conversation with the king; but he was soon released, and continued to live in privacy until the restoration. He was then called again into public life, and was raised to the primacy. He survived his elevation little more than two years, dying June 4, 1663.

## K

**K**;\* the eleventh letter of the English alphabet, representing a close articulation, produced by pressing the root of the tongue against the upper part of the mouth, with a depression of the lower jaw, and opening of the teeth, and differs, in most ancient and modern languages, from *g* hard only by a stronger pressure of the tongue, and a stronger expiration. (See *G*.) *K*, by the Greeks called *kappa*, is probably of later origin than *G*, as its most ancient form on monuments seems to be a contraction of gamma, i. e. in its first straight and its second bent form (I C). On the ancient coins of Crotona, Corinth, Syracuse, we find this sign, Q, from which the Roman Q originated. Both signs, according to Payne Knight, originated from the union of the double-bent gamma.

\* Where the reader may fail to find articles under *K*, he is referred to *C*.

In Latin, the *k* was superfluous, its place being supplied by *c*. The Greek *K* was not adopted by the Latins before the time of Sallust, and was only used in words which began with *ca*, as *Caesar*, *Castrum*, *Calumniator*; hence a *K* was branded on the forehead of calumniators. As an abbreviation, in Latin, it signifies *Kass* (a name), and several other words, *Kalendar*, &c. The Greek *K* stands, on coins, for *Kassus*, *Cæsar*, *Klaudius*, *Claudius*, *Kassius*, *Campania*, &c. It often also signifies *Carthage*. As an abbreviation, it often stands for *cas*, and *cassus*, common, *καλός*, colony, *καρ*, virgin, &c. The Greek *K* signifies twenty, and, with a perpendicular stroke under it, *K*, = 20,000. *K*, in Latin, is equal to 200; with a horizontal dash over *k*, *k̄*, = 250,000. In Hebrew, it answers to *kaph* or *ḥaph*. The Indians, Spaniards, and Portuguese, have borrowed the letter entirely from their alphabet. The French use a

only in words originally German, Breton, &c.; but, of late, it has become frequent in proper names of Oriental origin, on account of the numerous translations from Oriental languages into the French. In English, most modern writers drop it at the end of words of Latin origin, as *public*, *music*, &c., formerly *publick*, &c.; but, in monosyllables, it is retained on account of their derivatives. In Swedish, Danish, Dutch, Polish, *k* sounds as in English. *K* signifies, on French money, *Bordeaux*, and, on money coined at Crennits, *K* and *B* signify the mines of *Kermecz* and *Bánya*. *K*, before a vowel, is one of the easiest sounds children learn; but it is difficult, if it precedes another consonant. The *k*, at the beginning of a word, does not always belong to the root, but, like other aspirated letters, often a mere prefix. In German, it often originates from the reduplication *ge* and *g* (see *G*), particularly before a consonant.

KAABA; originally a temple at Mecca, in great esteem among the heathen Arabians, who, before they embraced Mohammedanism, called a small building of stone, in the same temple, *kaaba*, which has, in turn, become an object of the highest reverence with the Mohammedans. They say it was built by Abraham and Ishmael. On the side of it is a black stone, surrounded with silver, called *braktan*, set in the wall, about four feet from the ground. This stone has served, since the second year of the Hegira, as the *kebla*, that is, as the point towards which the Mohammedan turns his face during prayer. The pilgrims, or *hadgis*, touch and kiss this stone seven times, after which they enter the kaaba, and offer up their prayer. The Mohammedans first turned their face towards Jerusalem, until Mohammed ordered the present direction. Burckhardt (q. v.), in his *Travels in Arabia*, says "The holy kaaba is the scene of such indecencies, as cannot with propriety be more particularly noticed. They are not only practised with impunity, but it may be said publicly; and my indignation has often been excited at what drew forth only a laugh from other passengers." We find, therefore, that the Mohammedan pilgrimages produce the same disorders as those which attend Catholic pilgrimages that attract great numbers of people, and which have led to the prohibition of such pilgrimages in most Catholic countries. In some places, however, they still exist, with all their disorder and licentiousness, as, for instance, at Einsiedeln, in Switzerland. The same results take place in the numerous assemblages of other sects, of which instances might be cited from Europe; and camp-meetings have not unfrequently been charged with a like tendency. The evil is the natural consequence of assembling a multitude in a state of excitement.

KABARDA. See *Circassia*.

KABBALA. See *Cabala*.

KABUL. See *Afghanistan*.

KÆMPFER, ENGELBRECHT, a famous traveller, born at Lemgo, in 1657, and excellently educated by his father, a clergyman, studied medicine at Königsberg, performed a journey, in 1683, as secretary to a Swedish embassy, by land through Russia to Persia; after which he visited Arabia, Hindoostan, Java, Sumatra, Siam and Japan, in which last country he resided two years. In 1692, he returned, was appointed private physician of the count of Lippe, in his native city, and died in 1716. Of his writings, his *History and Description of Japan* is deserving of mention. This work was translated into English, from the manuscript in 1727, published at London in two folio volumes; and, in the German language, it appeared first at Lemgo, in 1774, edited by Dolm. The greater part of his manuscripts, rich in important observations, have not yet been printed. Sir

Hans Sloane purchased them from Kæmpfer's heirs, and they are now to be found in the British museum.

KÆSTNER, ABRAHAM GOTTHELF, a celebrated mathematician and epigrammist, born at Leipsic, in 1719, never attended a public school. From his tenth year, he received instructions in jurisprudence from his father, who was professor in Leipsic; and in his eleventh, he joined a debating society of several youths studying law. He applied himself to philosophy, physics, and mathematics; metaphysics in particular, according to his own statements, had peculiar attractions for him. It is remarkable, that he found addition and multiplication very difficult, even after he had made considerable progress in mathematics. He continued also the study of law. In 1739, he held disputations, and began to deliver lectures on mathematics, philosophy, logic, and jurisprudence. He also attended to belles-lettres. Having obtained a professorship extraordinary in 1746, he was, in 1756, established on advantageous terms, in Göttingen, as professor of natural philosophy and geometry. The study of mathematics was greatly promoted by his means. Among his numerous writings, which fill nine pages in Meusel's *Gelehrte Deutschland, his Geschichte der Mathematik* (1795) is the best. In general, his acute mind seems to have been too much directed to single points to allow him to grasp, and exhibit happily, the whole of the mathematical and physical sciences. He was not less celebrated for his wit than for the cultivation of the severer sciences. His epigrams, however, involved him in many quarrels. He died in 1800.

KAFFRARIA, and KAFFRES. See *Caffraria*, and *Caffres*.

KAIN, LE. See *Le Kain*.

KAISERSLAUTERN; a town on the river Lauter, with 4550 inhabitants, a gymnasium and seminary for teachers, in Rhenish Bavaria, on the Hardegebirge, famous, in modern times, for the battle of November 28, 29, and 30, 1793, between the duke of Brunswick and a division of the French army of the Moselle, under Hoche, which attempted to relieve Landau. Another battle was fought near Kaiserslautern, May 23, 1794, and a third, September 20, 1794, in both of which the French were unsuccessful. The passes leading from the Vosges to Landau and Metz, both of which are German frontier fortresses, are situated here.

KALAH (*Arabic*, a fort); a word which enters into the compositions of many geographical names of the East. *Kelat* has the same meaning.

KALAMATA. See *Greece*.

KALAND (probably from *Kalends*; a lay fraternity, which originated in Germany in the thirteenth century. The members assembled on the first of each month, to pray for their deceased friends, after which they took a repast in common. In the course of time, the religious purpose of the assembly was forgotten, and the meeting became one of mere festivity, so that, at last, the fraternity was abolished on account of its excesses. The word *kaland* exists to this day in proverbs, &c.

KALB, BARON DE, a major-general in the American army, was born in Germany, about the year 1717. When young, he entered into the service of France, in which he continued for forty-two years, and obtained the rank of brigadier-general. In 1757, during the war between Britain and France, he was sent, by the French government, to the American colonies, in order to learn the points in which they were most vulnerable, and how far the seeds of discontent might be sown in them towards the mother country. He was seized, while in the performance of this commission, as a suspected person, but

escaped detection. He then went to Canada, where he remained until its conquest by the British, after which he returned to France. In 1777, during the war of the revolution, he came a second time to the United States, and offered his services to congress. They were accepted, and he was soon after made a major-general. At first he was placed in the northern army, but when the danger which threatened Charleston from the formidable expedition under Sir Henry Clinton, in 1778, rendered it necessary to reinforce the American troops in the south, a detachment was sent to them, consisting of the Maryland and Delaware lines, which were put under his command. Before he could arrive, however, at the scene of action, general Lincoln had been made prisoner, and the direction of the whole southern army in consequence devolved upon the baron, until the appointment of general Gates. Aug. 15, Gates was defeated near Camden by lord Rawdon, and, in the battle, baron de Kalb, who commanded the right wing, fell, covered with wounds, while gallantly fighting on foot. A tomb was erected to his memory, by order of congress, in the cemetery of Camden.

KALCKREUTH, FREDERIC ADOLPHUS, count of, Prussian field-marshal, born at Eisleben, in 1737, entered the army in 1751. In the seven years' war, he served with distinction as aid of prince Henry, ascended, step by step, to the office of general, and was made a count in 1788. In the war with France, he manifested equal courage and ability. In 1793, he took Mayence. He contributed essentially to the victory of Mollendorf at Kaiserslautern, May 23, 1794. He soon after drove the French from Deux Ponts, and pressed forward to Saar Louis. Towards the end of 1795, he received the chief command of the troops in Pomerania, and, in May, 1806, was appointed governor of Thorn and Dantzig, and inspector-general of the cavalry. In the autumn, he joined the main army in Thuringia, but took no part in the battle of Jena and Auerstadt, being stationed in the rear. June 25, 1807, he concluded with Berthier, at Tilsit, the truce between Prussia and France, after which, in conjunction with Goltz, he concluded a peace with Talleyrand. He was immediately after appointed field-marshal. In January, 1810, the king appointed him governor of Berlin. In the last war, count Kalckreuth was governor of Breslau, and returned to Berlin in 1814, where he entered anew upon the government, and died in 1818. He was a man of rare qualities of mind and heart.

KALEIDOSCOPE; an instrument for creating and exhibiting an infinite variety of beautiful forms, pleasing the eye by an ever-varying succession of splendid tints and symmetrical forms, and enabling the observer to render permanent such as may appear appropriate for any branch of the ornamental arts. This instrument the invention of doctor Brewster, in its most common form, consists of a tin tube, containing two reflecting surfaces inclined to each other, at any angle which is an aliquot part of  $360^\circ$ . The reflecting surfaces may be two plates of glass, plain or quicksilvered, or two metallic surfaces, from which the light suffers total reflection. The plates should vary in length, according to the focal distance of the eye: five, six, seven, eight, nine and ten inches, will, in general, be most convenient; or they may be made only one, two, three or four inches long, provided distinct vision is obtained at one end, by placing at the other an eye-glass, whose focal length is equal to the length of the reflecting planes. The inclination of the reflector that is in general most pleasing is  $18^\circ$ ,  $20^\circ$ , or  $22\frac{1}{2}^\circ$ , or the 20th, 18th and 16th part of a circle; but the planes may be set at any required angle, either by a metallic, a paper, or cloth joint, or any other simple contrivance. When the two planes are

put together, with their straightest and smoothest edge in contact, they will have the form shown in figure 1, where A B C is the aperture or angle formed by the plates. In this figure the plates are rectangular; but it may often be more convenient to give them the triangular form, shown at N figure 2, or M figure 3:

When the instrument is thus constructed, it may be either covered up with paper or leather, or placed in a cylindrical, or any other tube, so that the aperture A B C may be left completely open, and also a small aperture at the angular point D. If the eye is now placed at D, and looks through the aperture A B C, it will perceive a brilliant circle of light, divided into as many sectors as the number of times that the angle of the reflectors is contained in  $360^\circ$ . If the angle is  $18^\circ$ , the number of sectors will be 20; and whatever be the form of the aperture A B C, the luminous space seen through the instrument will be a figure produced by the arrangement of 20 of these apertures round C as a centre, in consequence of the successive reflections between the polished surfaces. Hence it follows, that, if any object, however ugly or irregular in itself, is placed before the aperture A B C, the part of it that can be seen through the aperture will be seen also in every sector, and every image of the object will coalesce into a form mathematically symmetrical, and highly pleasing to the eye. If the object be put in motion, the combination of images will likewise be put in motion, and new forms, perfectly different, but equally symmetrical, will successively present themselves, sometimes vanishing in the centre, sometimes emerging from it, and sometimes playing around in double and opposite oscillations. When the object is tinged with different colours, the most beautiful tints are developed in succession, and the whole figure delights the eye by the perfection of its forms and the brilliancy of its colouring. The eye-glass placed immediately against the end of the mirrors, as well as another glass similarly situated at the other end, or of common transparent glass. The tube is constructed a little beyond this second glass, and, at its termination, is closed by a ground glass, which can be put on and off. In the vacant space thus formed, books, pieces of coloured glass, and other small, bright objects, are put. The changes produced in this position by turning the tube, give rise to the different figures.

Such is the construction of the single kaleidoscope, but various other forms have been given to it by the inventor. The polycentric kaleidoscope, consists of three or more mirrors, introduced into the tube, so as to form a prism of three or more sides. But there is a limit to the number of sides, for symmetrical images cannot be formed, if the mirrors be inclined to each other, at a greater angle than  $90^\circ$ . Hence, no

polygonal prism, having more than four sides, can be used in this instrument. Among four sided prisms, the square and the rectangular parallelogram, are the only ones that can be introduced, and among triangles only such as have for their angles the quotients obtained by dividing  $360^\circ$ , by 4, 6, 8 or 12, so that we may have a triangle having its angles

First,	$60^\circ$ ,	$60^\circ$ ,	$60^\circ$ , or
Second,	$90^\circ$ ,	$45^\circ$ ,	$45^\circ$ , or
Third,	$90^\circ$ ,	$60^\circ$ ,	$30^\circ$ .

The square polycentral kaleidoscope is the least pleasing of any, for it exhibits the same set of images in longitudinal stripes; and the same holds with the rectangular, excepting that the stripes are longer in one direction than another. The equiangular triangle form gives a very pleasing set of images, arranged symmetrically in three different directions, for which reason it has been called the *Triscope*. When the section of the prism is an isosceles right angled triangle, the resulting images are exceedingly beautiful, being arranged symmetrically by fours at a time in squares; this form of the instrument is called the *Tetrascop*. When the angles of the triangular section are respectively  $90^\circ$ ,  $60^\circ$ , and  $30^\circ$ , the images arrange themselves in hexagons. Of all the forms above specified, the two last seem best calculated to assist the pattern-drawer in his designs.

On reflection, it is manifest that the object or objects in the case at the end of the tube, must be removed at some distance from the end of the mirrors, which will impair the effect in some degree. This may be obviated by removing the object to a considerable distance from the ends of the mirrors, and placing a convex lens, so that the image of the objects may be formed just at the ends of the reflectors. The spectra of the kaleidoscope may be thrown upon a wall or screen in the manner of the magic lantern, or solar microscope, and sketched by the draughtsman; but the light must be very strong to produce a clear and vivid picture.

**KALI**; a genus of marine plants, which are burnt to procure alkali. See *Alkali*, and *Kelp*.

**KALLIPYGOS**. See *Venus*.

**KALMIA**; a beautiful North America genus of shrubs, having coriaceous, ever-green and cup-shaped flowers, of a fine rose or purple colour, disposed in large corymbs. The corolla is provided with ten little pits, prominent externally, and in which the anthers are confined. It is naturally allied to *rhododendrum*. The *K. latifolia*, commonly called *mountain laurel*, or *calico bush*, is a large shrub, growing most abundantly on and about the Alleghany mountains, but sometimes in the vicinity of the ocean, in the Middle and Eastern States, as far north as lat.  $43^\circ$ . The trunk is sometimes three inches in diameter, and the wood is very hard, susceptible of a fine polish, and more nearly resembles box than any other North American wood. This shrub is in great request in the European gardens, from the beauty of its flowers and foliage. The other species of *kalmia*, four in number, are much inferior in stature and the size of the flowers, though still highly ornamental.

**KALUGA**; an extensive government of European Russia, bounded by those of Moscow, Smolensko, Tula and Orel, lying between  $35^\circ 48'$  and  $37^\circ 22'$  E. lon., and  $51^\circ$  and  $54^\circ 30'$  N. lat. Its territorial extent is 8500 square miles. Its population was, in 1796, 853,000, and is now about 1,176,000. The chief products are corn, hemp, and flax. The chief rivers are the Oka, the Upa, and the Schisdra. This province contains iron mines.

**KALUGA**; capital of the above government, on the Oka. It has some very good public buildings, such as the high church, government house, &c.; but in other respects, it is irregular, most of the

houses being of wood, and ill built. Population, 25,000; 107 miles south-west of Moscow; lon.  $36^\circ 3'$  E.; lat.  $54^\circ 3'$  N.

**KAMEN**, or **KAMIEN**; a Slavonic word signifying *rock*, *stone*, and found in many geographical names, as *Kamin*, *Kamientz*, *Kaminietz*, &c.

**KAMTSCHATKA**; a large peninsula on the north-eastern coast of Asia, forming a district. On the east, it has the North Pacific ocean, and on the west that large gulf of it called the *sea of Okhotsk*. It extends from the  $51^{\text{st}}$  to the  $62^{\text{d}}$  degree of north latitude, and from  $155^\circ 10'$  to  $173^\circ 20'$  east longitude, and is reckoned upwards of 600 miles in length, and nearly 300 in breadth; square miles, 85,000. It is remarkable for its extreme cold, which is heightened by a range of very lofty mountains, extending the whole length of the peninsula. Several of these mountains are volcanic; but the most remarkable is one situated near Nijni Kamtschatsk, the volcano of which is very active, and two years seldom elapse without some violent eruption. Kamtschatka scarcely enjoys three months of an imperfect summer, and is very deficient in vegetable productions, particularly grain. It has a great variety of animals which produce the richest and most valuable furs. The sable is more plentiful here than in Siberia, though its fur is not quite so beautiful. There are several varieties of the Arctic fox, or fire fox, in Kamtschatka. Other common animals are the beaver, the hare, the marmot, and the argali or wild sheep. The bear is the most formidable wild animal, and the hunting of it the most serious occupation of the Kamtschadales. The coasts and rivers swarm to a most extraordinary degree with fish, which form the main article of food of the inhabitants. The excellence of the salmon, herrings and different kinds of shell-fish, is particularly remarked. The air is also filled with game, particularly woodcocks, snipes, grouse, wild geese and ducks, the eggs of which last are collected by the natives, and preserved in the fat of fish. The only vegetable productions are stunted birch, and dwarf pines and cedar. Shrubs are more plentiful, such as the mountain ash, wild rose and raspberry. There is also a variety of berries. Copper and iron are worked. Sulphur abounds; and many minerals are found in the mountains. The trade of Russia with Kamtschatka is carried on from Irkoutsk by the difficult and tedious route of Okhotsk. The imports, besides brandy, are nankens and other Chinese stuffs, together with various commodities of Russian and foreign manufacture, as ribbons, handkerchiefs, stockings, caps, shoes, boots, and, in general, all articles of European consumption, but in small quantity, and bearing a very high price. The only export is furs, the amount of which is valued at from 50,000 to 100,000 roubles. The capital is Nijni Kamtschatsk, with 300 inhabitants. The inhabitants are, in general below the common height, have broad shoulders and large heads. The face, and particularly the nose, is long and flat, the eyes small and sunk, the lips thin, and they have scarcely any beard. In 1690, the Russians had some knowledge of this country. In 1696, they sent thither a detachment of Cossacks, under Morosko. The next year, part of the country was rendered tributary; but it was not till 1766, that all Kamtschatka was surveyed and occupied by the Russians. The sway which they have established is by no means severe; notwithstanding which, the Kamtschadales, like all savage nations coming in contact with civilized, have suffered deeply from the connexion. The number of inhabitants now amounts to only about 4500, of which about 1500 are Russians and Cossacks. A century since, the number was twenty or thirty times larger. This diminution is to be ascribed to their bloody struggles to shake off

the Russian yoke, to the small fox, the unnatural practices of the women to procure abortion, and to their excessive indulgence in spirituous liquors. There is besides a class of criminals banished to this inhospitable region, and a varying population of merchants, hunters, and seamen. The Kamtschadales are an ugly branch of the Mongol race, and call themselves *Itelmes*. They are good natured and hospitable, but given to the grossest sensuality. They are excessive eaters, practise lascivious dances, and are very dirty. Every Kamtschadale village (*ostrovochok*) consists of several summer dwellings, built on piles, rising several feet from the ground; the occupants enter by ascending notched trunks of trees. In winter, the occupants of half a dozen of these *balagans*, as they are called, collect into a *jurta*, or winter dwelling, five feet deep, covered by a cone-shaped roof, and which cannot be entered, except by ascending the roof, and going down the chimney through the smoke. The clothing of the Kamtschadales is prepared from the skins of reindeer or dogs, but much of the Russian style of dress has been introduced. The Kamtschadale women alone perform the household occupations, while the men take their ease, if necessity does not drive them to hunt, or to fish, or to prepare tools for both these occupations, or to build sledges and houses. The objects of the chase are the fur-bearing animals and the reindeer; the principal fish taken are the whale and the seal. Barley, potatoes, turnips, cabbage, hemp, cucumbers, horse-radish, are mostly cultivated only by the Russians. The chief food of the Kamtschadales consists of fish, seasoned with whale and seal fat, and a kind of paste prepared of the tender birch bark. Their favourite drink is the juice of the birch. The chief domestic animal is the dog, which serves for draught, and the skins furnish clothing. To prepare the dogs for draught, they are castrated, and four to eight are attached to a little sled, sixteen pounds in weight, and capable of carrying a man, at the rate of four or five miles an hour. These dogs require to be fed only in the winter; in the summer, they live on the fish which they pick up on the shores of the sea and the rivers. The Kamtschadale does not tame the reindeer, although all the neighbouring people do. Since 1820, swine and hens have been found here. The religion of the Kamtschadales was, and is still among the few who have not embraced Christianity, *Shamanism*. But even the Christian Kamtschadales have not relinquished their sorcerers or *shamans*. They believe in an almighty God, creator of the world, called *Kutka*, but do not worship him, because their innumerable *fetiches* absorb all their attention. They believe in the immortality of the soul, which they also ascribe to the meanest brute. They give to animals speech and reason, and believe that dogs are making inquiries of strangers when they bark at them. They relate also that, ages ago, a universal deluge covered the earth, out of which only one pair of human beings were saved.

**KANGAROO** (*macropus*, Shaw). These extraordinary animals, which are peculiar to Australasia, belonging to the marsupial order of quadrupeds (those with an abdominal pouch), from the other genera of which they differ by having but two kinds of teeth, the canine being wanting. Their incisors are six in the upper jaw, and but two in the lower; the former short, and the latter long. The molars, which are separated from the incisors by a large vacant space, are ten in number in each jaw. The limbs of the kangaroo are strangely disproportioned; the fore legs being small and short, whilst the hinder are long and powerful. The tail is very thick at its base, gradually tapering, and appears to act as a supplemental limb, when the animal assumes its usual

erect or sitting posture, in which position it is supported by the joint action of the tail and hinder legs. This conformation also enables it to take amazing leaps. The fore feet are furnished with five toes, each terminating in a moderately strong and hooked claw. The hinder feet, on the contrary, are provided with only four toes, one of which is long, of great strength and terminated by a large and powerful claw, like an elongated hoof. The head and upper parts are small and delicate, and appear disproportioned to the posterior parts of the animal, which are robust and powerful. They use their tails and hinder feet as weapons of defence. When they are pursued and overtaken by dogs, they turn, and, seizing them with their fore feet, strike them with their hinder extremities, and often tear them to such a degree as to destroy them. The kangaroos feed entirely on vegetable substances, chiefly on grass. They associate in small herds, under the guidance of the older males. The female has two mammae in the abdominal pouch, on each of which are two teats; the younger at birth are very diminutive, not exceeding an inch in length. At this time, the mouth is merely a round hole, just capable of embracing the extremity of the nipple; but gradually enlarges, till it can receive the whole of this part into its cavity, where it lies in a groove formed in the middle of the tongue. The young continues to reside in the pouch, till it has attained maturity, occasionally leaving it for exercise or amusement, but immediately seeking refuge in it on the least alarm. The flesh of these animals used to be nutritious and savoury, somewhat resembling mutton. They are capable of being domesticated, in which state they are harmless and even tame. The species of these singular animals have not hitherto been satisfactorily determined, as the differences on which the distinguishing characters of each have been founded, are merely those of size and slight modifications of colour.

**KANSAS.** See *Indians*.

**KANSAS**, or **KANZAS**, or **KANSEZ**; a river of North America, which rises in the Rocky mountains, and, after an easterly course of about 1800 miles, unites with the Missouri, 340 miles from the Mississippi, in lon. 94° 20' W.; lat. 34° 31' N.

**KANT**, **IMMANUEL**, born in Königsberg, a Prussia Proper, April 22, 1724, was the son of a business-maker, in the suburbs of his native place—a man of integrity and respectability, though of a humble station. Kant's mother was a woman of great piety, and much attached to the strict tenets and discipline of doctor Schulz, a professor of theology at the university of Königsberg a distinguished divine in his day. Though far from being in easy circumstances, his parents resolved to bestow upon their son Immanuel the advantage of a liberal education. After having learned to read and to write in the charity school of the suburb, Kant was sent, in 1732, to the *Collegium Fredericianum*, at the suggestion of doctor Schulz, who, even at that early period, had the prescience to discover the talents of the boy. At this school, he contracted an intimate friendship with Ruhnken, afterwards so celebrated as a philologist. But were indefatigable students, and read and studied much together. It is remarkable that, at this period, Kant devoted his attention principally to philological studies, while his friend Ruhnken seemed to have more fondness for philosophy. In the maturer years, they exchanged pursuits. In 1746, Kant repaired to the university of his native city, and, at first, studied theology, in consequence of the necessity of depending entirely on his professors for future maintenance. But at no period did he neglect philosophy and mathematics. Hardly had he arrived at the age of manhood, when he lost both his parents.

who, indeed, had never been able to afford him much pecuniary assistance; but he was fortunate enough to meet some relations, whose aid, together with his own industry and economy, enabled him to continue his studies. His application was uncommonly great, as is proved by his bold and successful attacks on the doctrines of Leibnitz and Wolf, and his skilful use of the weapons of dialectics against the authority of the most eminent metaphysicians of the day, when he was but twenty-two years of age. After a residence of about three years at the university, he acted in the capacity of a private tutor in several families, and lived about nine years with count Hüllesen, at Arnsdorf. Kant read much in this retirement, and traced the outlines of several of those philosophical treatises, which were soon afterwards published in rapid succession. In 1755, he returned to Königsberg, took the degree of M.A., and produced on this occasion, in the form of an inaugural dissertation, his treatise, entitled *Principiorum primorum Cognitionis metaphysicæ nova Dilucidatio*. In the same year, he published his celebrated work on the Universal Natural History and Theory of the Heavens, or an Essay on the Constitution and Mechanical Structure of the whole Globe, according to the Newtonian System. In this treatise, he anticipated several of the subsequent discoveries of the astronomer Herschel, particularly the planet called after his name. Kant began to lecture, as *doctor docens*, on logic, metaphysics, mathematics, and natural philosophy, to which, at subsequent periods, he added natural law, moral philosophy, natural theology, and physical geography. He soon became popular with the students; but it was long before he obtained a professorship. He had no ambition beyond that of being useful in the sphere which he had chosen, nor could his noble and strictly upright character resort to any kind of art to promote his worldly interest. In 1756, the *professor extraordinarius* of philosophy, Mr Knutzen died; but Kant solicited in vain the vacant chair. In 1758, the *professor ordinarius* of philosophy died; but Kant was not appointed in his stead, though zealously aided by doctor Schultz. In 1766, he accepted the unsolicited situation of second keeper of the royal library, to which a small salary was attached; and, at the same time, he undertook the management of a private cabinet of curiosities. But these offices he resigned in 1772, on account of the interruptions to which he was exposed by the necessity of showing the books and rarities to strangers. In 1770, he was at length advanced to the ordinary professorship of logic and metaphysics in the university, to the lustre of which he had already so long contributed. He was now placed above the fear of want, and could employ his talents in a manner satisfactory to himself. Upon this occasion, he produced his celebrated inaugural dissertation, *De Mundi sensibilis atque intelligibilis Forma et Principiis*. In 1787, Kant was made a member of the royal academy of sciences at Berlin. Having once attained independence, his wish to improve his worldly concerns seems to have aspired no higher. He declined various advantageous proposals to transfer his talents to other universities, and, at length, died by a gradual decay, Feb. 12, 1804, in the eightieth year of his age, having witnessed the great sensation which his philosophy produced among his countrymen, though his patience was exposed in this particular also to severe trials. Six years elapsed before much notice was taken of his great work, the Critique of Pure Reason; and it is even said, that the publisher of it was about to use the numerous copies of the work which remained on hand as waste paper, when the demand suddenly increased, and three editions were disposed of in quick succession.

Kant never went farther from Königsberg than to Pillau, seven German miles (about thirty-two English) distant. In the earlier part of his life, he used to dine at the ordinary of the principal tavern; to which custom he was undoubtedly indebted in part for his knowledge of mankind. Reichardt, in the *Urania* (a German souvenir) of 1812, describes Kant as an extraordinary lean, small man. "Lean, nay, drier," he says, than his small body, none probably ever existed, and no sage probably ever passed his life in a more tranquil and self-absorbed manner. A high, serene forehead, a fine nose, and clear bright eyes, distinguished his face advantageously. But the lower part of his countenance was marked with a strong expression of sensuality, which was conspicuous in his habits at table. He loved a mirthful company at a good dinner, and was himself an agreeable companion, who never failed to entertain and enliven the company by his extensive knowledge, and an inexhaustible store of pleasing anecdotes, which he used to tell in the driest way, without ever laughing himself; and by the humour of his repartees and observations. Kant's company was sought for by the first families of Königsberg, the more so as he stood in the greatest esteem for his virtue and a noble pride, which well became the most distinguished man of the city, and one of the deepest philosophers who have ever lived. He was, in his exterior, always neat, and even highly dressed. Kant was also fond of playing at cards, and he did not like to spend an evening without a game at ombre. He considered it as the only certain means of withdrawing his mind from deep thought, and tranquillising it. He possessed a boundless memory, which added much to the interest of his lectures, as he interspersed them with many illustrations, with which his immense reading in history, biography, travels, and novels, in fact, all works which could add to the stores of his knowledge, amply supplied him. Though he had his notes before him, he seldom looked at them, and often quoted whole lines of names and dates from memory. His library was very small, but he had made a contract with a bookseller, who sent him all new publications, which, after reading, he sent back. He lectured the greater part of the forenoon, allowing himself twenty minutes' rest between each lecture. In the afternoon, he lectured seldom. He rose early, and studied then most ardently. His lectures on abstract philosophy were much easier to be understood than his works, because, in the former, he added many elucidations, examples, and explanations, which he thought unnecessary in his printed works. Besides the great merits of Kant in regard to intellectual philosophy, we owe him much for his virtue and inflexible morality, which he placed again on their true elevated basis, after they had been referred exclusively to interest by Helvetius and others.

As to the philosophy of this profound thinker, a full account cannot be expected in a work of this sort; a glance at it will be all which we can give. The inquirer into Kant's philosophy should be careful not to reject immediately what he cannot understand, and ought not to expect to understand, without deep study and strict mental discipline. To form an opinion of a whole philosophical system from the pages of a review, is more easy than satisfactory or profitable. In fact, a man can hardly hope to acquire a good idea of Kant's philosophy without reading him in the original. When Kant appeared, two philosophical systems were most in vogue—that of Locke and his followers, and that of Leibnitz, Wolf, &c. Kant saw that little aid was rendered to the cause of truth by a dogmatic philosophy, whether founded on sensualism or idealism. He wished for certainty in the field

of philosophy, and put to himself the questions—What can I know? What is it that I know originally? The acute scepticism of Hume had its influence upon him. Hume proved very satisfactorily, that our ideas of cause and effect are not derived from experience; but he rashly concluded, as Kant observes, “that they are the spurious offspring of the imagination, impregnated by custom.” Kant discovered that Hume had been led to this hasty inference in consequence of having taken too limited a view of the great problem which he had thus partially attempted to solve. He perceived that the idea of cause and effect is by no means the only one which the mind makes use of with the consciousness of its necessity, yet without having derived it from experience. This he found in his endeavours to ascertain what we can know, which led him to the fundamental laws of the mind. Having arrived at this conclusion, he strove to ascertain the exact number of these original or transcendental ideas, or imperative forms; that is, such ideas as we do not derive from experience, but by which, on the contrary, we acquire experience. In the first rank of these, are *space* and *time*. Kant shows that all our perceptions are submitted to these two forms: hence he concludes, that they are within us, and not in the objects; they are *necessary* and *pure intuitions* of the internal sense. Truths acquired by experience never carry with them that absolute certainty; for instance, experience teaches us that the sun rises every day; that all men are mortal; yet we may imagine a day when the sun does not rise, and a man who does not die; but imagination itself cannot suppose any thing unconnected with space and time. This primitive intuition must have, as its basis, the primary laws of the understanding, without which we can comprehend nothing. As far as the transcendental ideas, or, as Kant calls them, *categories*, extend, so far extends the knowledge of the understanding *a priori*. Kant was at great pains in endeavouring to ascertain the number of these categories, and he found them to be all comprehended under the four classes of quantity, quality, relation, and modality. The categories themselves are twelve in number. Under the first head are comprised *unity, multitude, totality*; under the second, *reality, negation, limitation*; under the third, *substance and accident, cause and effect, action and reaction*; under the fourth, *possibility, existence, necessity*. These categories are necessary and indispensable for our understanding, as the forms of space and time were for our perceptions; we cannot figure to ourselves any thing without the relations of cause and effect, of possibility, quantity, &c., which, with other words, is, we cannot perceive anything except by these original, necessary, unchangeable forms of thought. Hence the demonstrative certainty of mathematics, the objects of which—space, time, quantity, &c.—lie in the necessity of the forms of thought, and not in the range of error to which experience is subject. To produce results, the categories are applied to exterior objects, objects of experience, in which application they are subject to error. The three original faculties, through the medium of which we acquire knowledge, are *sense, understanding, reason*. Sense, a passive and receptive faculty, has, as has been already stated, for its forms or conditions, *space* and *time*. Understanding is an active or spontaneous faculty, and consists in the power of forming conceptions, according to the categories already given, which categories are applied to objects of experience through the medium of the two forms of perception, *space* and *time*. Reason is the third or highest degree of mental spontaneity, and consists in the power of forming ideas. As it is the province of the understanding to form the intuitions of sense into

conceptions, so it is the business of reason to form conceptions into ideas. The work in which Kant endeavoured to ascertain these categories and the province of certain human knowledge, is his *Kritik der reinen Vernunft*—Critical Inquiry into the Nature of Pure Reason (first edition, Riga, 1781; sixth edition, Leipsic, 1818). Far from rejecting experience, Kant considers the work of all our life to be the action of our innate faculties on the conceptions which come to us from without. The philosophy thus started was called *critical philosophy*—a very poor name, but which has now become settled. Kant proceeds in a similar way with morality; the idea of good and bad is a necessary condition, an original basis of morals, which is supposed in every one of our moral reflections, and not obtained by experience. He treats this part of his philosophy in his *Kritik der praktischen Vernunft*—a Critical Inquiry into Practical Reason (1788; fifth edition, Leipsic, 1843). Kant places unreservedly on two parallel bases all the arguments for and against human liberty, the immortality of the soul, the transitory or eternal duration of the world; and resorts to the feelings to make the balance incline, because the metaphysical proof on the opposite sides are equally great. Three opposite arguments on great questions are called, in the works of Kant, *antinomies*. In aesthetics, also, he pursues a similar course, and treats it in his *Beobachtungen über das Gefühl des Schönen und Erhabenen* (Riga, 1771)—Observations on the Feeling of the Beautiful and Sublime. Another important work of his is the *Kritik der Urtheilskraft*—Critical Inquiry into the Faculty of Judgment (Berlin, 1790; third edition, 1799). We must also mention *Metaphysische Anfangsgründe der Rechtslehre*—Metaphysical Elements of Legal Science (1797; second edition, 1803); *Metaphysische Elemente der Ethik*—Metaphysical Elements of Ethics (1777; second edition, 1803); *Metaphysical Elements of Natural Science* (1786; third edition, 1800); a *Pragmatical Treatise on Anthropology* (1798; third edition, 1821); *Of Perpetual Peace* (1796); *Religion considered within the Limits of Reason* (1793); the only possible Evidence for demonstrating the Existence of the Deity (1763; last edition, 1794). Most of Kant's smaller treatises, full of acute remarks, are contained in his *Kleinere Schriften*—Smaller Works (Königsberg and Leipsic, 1797, 3 vols.), and in the collection edited by Tieffrunk (Halle, 1799, 3 vols.). His friend the physician, published Kant's work, *Of the Power of the Mind, by mere Resolution, to control its unbid feelings*, with notes (second edition, Leipsic, 1824). Kant, of course, met with many opponents, the most prominent among whom were Mendelssohn, Hamann, Feder, Garve, Platner, Flatt, Jacob Herder, and particularly G. C. Schulze, as *Ernst Schulze* (1792), and in his *Kritik der Theoretischen Philosophie* (Hamb., 1801, 2 vols.). But his adherents were the more numerous party, and his philosophy has been taught in all the German universities, excepting the Catholic ones. A very good enumeration of Kant's works, and those of his opponents, as well as of his commentators and followers, is to be found in Tennemann's *History of Philosophy*, or Cornier's *Manuel de l'Histoire de la Philosophie*, traduit de l'Allemand de Tennemann (Paris, 1820, vol. 2).

KAPNIST. See *Capnist*.

KARA, in the Tartar languages; black, as *Karmania* (black people, country of the). In opposition to another word of the same idiom which signifies *white* and *free*, *kara* has been used to signify *tributary*, e. g., *kara Kalpacks* (tributary Kalpacks).

KARAITES. See *Caraites*.

KARAMSIN, NICOLAS, imperial Russian historiographer, born in 1765, educated at Moscow, in the house of professor Schalen, entered the military ser-

vice, and travelled, from 1789 till 1791, through Middle Europe. He is esteemed by many the first original prose writer of Russia. Of his History of the Russian Empire, eleven volumes had appeared in 1824. It has been translated into French, both at Paris and St Petersburg. This history extends to 1613, to the house of Romanoff. His other writings are Letters of a Russian Traveller, *Aglaiä*, a collection of tales (Moscow, 1794, 2 vols.), &c. His songs are too sentimental. The emperor Alexander conferred on him the order of St Anne, and gave him 60,000 rubles for the publication of his great work. A free residence was also allowed him in a pleasure castle of the empress Catharine II., and all the archives opened to him. The third edition of Karsmin's works appeared in 1815, in nine volumes. Of his History of the Russian Empire, in the original, the second edition appeared in 1818. When on the point of making a journey into foreign countries, he died, June 3, 1826. Just before his death, the emperor had granted him a pension of 50,000 rubles, which was continued to his widow and children. Dr Bowring has translated some of his poems.

**KARIKAL**; a French city on the coast of Coromandel, surrounded by the British territories, twenty-six leagues from Pondicherry, under the jurisdiction of which it is. It produces a net revenue of 300,000 francs a year. Population, 15,000; population of the territory, about as many more.

**KARL**; the German name for *Charles*, appearing in many geographical names, as *Karlstadt*, *Karlsruhe*, *Karlsbad*. *Karl* is of the same origin as *kerl*, which means, at present, a strong, sturdy fellow, formerly a valiant, powerful man. It is the same with the English *ceorl*, or *churl*.

**KARLSBAD**, **KARLSRUHE**, **KARLSTADT**, &c. See *Karlsbad*, &c.

**KARSCHIN**, **ANNA LOUISA** (properly *Karsch*), a German poetess, was born December 1, 1722, near Schwibus, on the frontiers of Silesia. Her father kept an alehouse. He died while she was young, and her mother, fearing that the eagerness for reading and writing which she displayed would make her neglect domestic occupations, withdrew her from the house of her uncle, who had undertaken the care of her education, and employed her three years in taking care of the cows; but she still contrived to gratify her desire of knowledge; for, having become acquainted with a shepherd boy who brought her books, mostly poor ones, she read them secretly. Her mother married her to a weaver, whom she never had seen. This union was unhappy, and, after eleven years, was terminated by a divorce. She was now utterly destitute; and, a year after, her mother married her to a drunken tailor, Karsch, whom Karschin hated. She now supported herself by selling occasional poems of her own composition, and by exhibiting as an improvisatrice about the country; but her drunken husband spent all her money. She finally attracted the attention of some influential man, and went to Berlin, where Ramler, Mendelssohn, Gleim, &c., encouraged her. Sulzer, who called her the *German Sappho*, published some of her poems in 1764, which produced her a considerable sum. She was admitted into the first society, and received several small pensions, but was not able fully to support herself, her two children, and her brother. Frederic II. took no interest in her, and did not give her the pension he had promised; but his successor, Frederic William II., ordered a convenient house to be built for her, which, however, she did not enjoy long, as her death took place in October, 1791. Her daughter published part of her poems, with her life, in 1792; new edition, 1796.

**KASAN**; an extensive province or government of

European Russia, lying between 46° 20' and 49° 40' E. longitude, and 54° and 57° N. latitude, and surrounded by the governments of Viatka, Orenburgh, Niznei-Novgorod, and Simbirsk. Its territorial extent is over 22,000 square miles; its population about 1,000,000, partly Russians, and partly Tartars, though of very mixed origin. The rivers are the Wolga, the Kama, the Sura, the Viatka, and the Kasanka, besides smaller streams, and a great number of lakes.

**KASAN**; a city of Russia, on the Kasanka, about four miles above its junction with the Wolga. Many Mohammedan Tartars still reside there, engaged in business. It is a bishop's see, and the seat of a small university, founded in 1803. It has also several other schools. Here are large soap-works and tanneries; also manufactures of woollen, cotton, lace, and earthen ware. It carries on an extensive trade. The caravans to Bucharia and China pass through Kasan. At a little distance from Kasan is a new admiralty establishment, with a navigation school, magazines, and a dock-yard, where galliots are constructed, and sent down the Wolga to the Caspian sea. Population, 25,000; 208 miles E. by S. Niznei-Novgorod; long. 49° 21' 9" E.; lat. 55° 47' 51" N.

**KATAHDIN**; a mountain in the state of Maine, North America, situated between the eastern and western branches of the Penobscot river, detached, steep on all sides, and extremely rugged. It was reputed, by the aborigines, to be the residence of supernatural beings. But few persons have visited its summit. It commands a very extensive view, embracing no less than sixty-three lakes. Its height, as ascertained by barometrical observations, is 4685 feet above the level of the west branch of the Penobscot at its base, and about 5335 feet above the ocean. It may be seen, in a clear day, from Bangor, a distance of seventy miles, and from Dixmont, eighty miles distant.

**KATT**. See *Frederic II.*

**KATZBACH**; a small river in Silesia, passing near Leignitz, famous for the victory which the Prussians and Russians under Blücher gained, August 26, 1813, over the French under Macdonald, Ney, Lauriston, and Sebastiani. It rained from August 24th to the 28th. Fire-arms could not be used, and the battle was fought hand to hand. It was short, and was terminated by a furious struggle between the Prussian cavalry under Blücher and the French under Lauriston, together 8,000 men. The French were broken, and were driven, horse and man, into the raging Neisse and Katzbach. Great numbers perished in the swollen streams. The result of the battle was more surprising, as a great part of the Prussian troops were raw militia. It is one of Blücher's greatest victories. During the battle and the following days, 103 French cannon were taken, two eagles, and 18,000 prisoners. Silesia was delivered, and the consequences were most important, particularly for Bohemia. The battle of the Katzbach took place on the same day that Napoleon repelled the attack of the allies on Dresden.

**KAUFMANN**, **ANGELICA**, a distinguished painter, was born at Coire, in the Grisons, in 1741, and received her first instruction in drawing and painting from her father, who, at the time of her birth, was painter to the bishop. Her admiration of the beautiful was early developed. She loved music, and made great progress in painting, under the guidance of her father, whose talents were but moderate, and whom she soon excelled. On her first journey to Italy, where she resided from her thirteenth year till 1769, in Milan, Florence, Rome, and

Naples, she acquired great skill; and her subsequent visit to London, where she painted the whole royal family, increased her reputation and improved her circumstances. Here she was elected a member of the royal academy, and here, also, she contracted an unfortunate marriage, of which the following circumstances are related. An English artist, who had paid his addresses to her, offended by her refusal, determined on vengeance. A handsome young man, chosen from the lowest class, was enabled to appear in the house of Angelica, and to become her suitor. She suffered herself to be deceived, and became his wife. The rejected artist now disclosed the deceit. Angelica obtained a divorce, but was obliged to settle an annuity on her husband. He, however, soon died. After her return to Rome in 1782, she was married a second time, more happily, to a Venetian painter, Zucchi, but she never had any children. Zucchi, likewise, died long before her. Angelica then devoted herself to painting till her death, in 1807. Her bust was placed, in 1808, in the Pantheon. She left a select library, some beautiful original paintings of old masters, and a considerable fortune, which she divided among several individuals and charitable institutions. She painted many portraits and historical pictures, the latter chiefly after antiques. She preferred ideal female figures. Her works are remarkable for grace, though the critic may discover in them incorrectness of style and sameness of plan and execution.

KAUNITZ, WENCESLAUS ANTHONY, prince of, knight of the golden fleece, fifth son of count Kaunitz, and one of nineteen children, was born in Vienna, in 1711, and was at first destined for the church, but, after the death of all his brothers, engaged in political life. His talents, aided by a favourable exterior, opened a brilliant career to him. After having studied at Vienna, Leipsic, and Leyden, he entered upon his travels, in 1732. In 1741, he was sent to pope Benedict XIV., and to Florence, on a secret mission, by Maria Theresa. In 1742, he went as Austrian ambassador to Turin, where he accomplished his mission to unite Sardinia more closely with Austria against the Bourbon courts so successfully, that, in 1744, he was appointed minister at the court of Charles, duke of Lorraine, then governor-general of the Austrian Netherlands. He conducted the most difficult affairs, in a highly critical state of the Netherlands, to the greatest satisfaction of the empress; but his feeble health obliged him to ask his dismissal, and he returned to Vienna. Soon afterwards, however, he appeared as minister plenipotentiary at the congress of Aix-la-Chapelle (q. v.), where he laid the foundation of his fame as a diplomatist. From 1750 to 1752, he was minister at Paris, and prepared the union of Austria and France, which took place in 1756. In 1753, he had been made court and state chancellor, and, in 1756, was created chancellor of Italy and the Netherlands. Thus he not only managed the foreign affairs of Austria, under Maria Theresa, but had also the greatest influence upon the domestic concerns. In 1764, the emperor, Francis I., raised him to the dignity of prince. As long as Maria Theresa lived, her confidence in Kaunitz was unbounded; but the emperor Joseph did not implicitly follow his advice; of which the unsuccessful attempt to open the Scheldt and to exchange Bavaria, as well as the unfortunate war with Turkey, were consequences. Under the reign of Leopold II., the influence of prince Kaunitz was still less. When Francis II. ascended the throne, his advanced age induced him to resign the office of court and state chancellor. He made up his opinions slowly, and after mature consideration. Voltaire was his favourite author, and he had much esteem

for Rousseau, who had been for a few weeks his private secretary at Paris. In Lombardy and the Netherlands, he instituted academies. Learned men found free access to him, and he cultivated the arts. The school of art at Vienna is almost entirely his work. Several painters and engravers were indebted to him for his patronage. His love of dress was considered extravagant. He was strictly honest and faithful. He rarely laughed, yet he was affable to all below him in rank. Under Joseph's government, Kaunitz ceased to appear at court, but the emperor often went to visit him, and received much assistance from him in his ecclesiastical reforms; hence he was called, by the court of Rome, *il ministro celato*, yet, when the pope was at Vienna, he gave him, as a matter of policy, not the back, but the palm of the hand to kiss, which was formerly considered the highest favour; but the prince, pretending not to understand this etiquette, took the hand of the pope in his, and gave it a hearty shake. He died in 1794, with the reputation of one of the ablest ministers Austria had ever produced, and the still greater fame of a man of noble character. No minister was ever treated with a longer and more intimate confidence, which was founded equally on his talents and his strict integrity.

KEAN, EDMUND, the most brilliant and effective tragic actor of the age, was the reputed son of a Miss Carey, strolling actress and itinerant vendor of perfumes, and an Edmund Kean, a scene carpenter. He was born in London, on the 17th March, 1787, or, according to other statements, 1789. His father procured a situation for him as a figurant in the pantomimes at Drury-lane theatre, when he was only two years old; but here, by the unnatural and forced positions which he had to practise in order to make his limbs more pliable, he became deformed. Some of the actors procured him surgical assistance, his limbs were supported, and he finally overcame his bodily defects. At seven years, his mother sent him to a little school; but order and obedience were not in his character, and he engaged himself as cabin-boy in a vessel going to Madeira. This situation, however, equally displeased him, and, to deliver himself in Madeira, he feigned deafness, and played his part so well, that the captain sent him home. In London, he could not find out his mother; but a woman who had him under her care recommended him to Miss Tidswell, an actress at Drury-lane theatre, who gave him much assistance. At one period, after his return to London, he exhibited as a droll, in a booth. After this, he was placed in one of the minor theatres, and was much applauded in Rolin's address to the Peruvians. From this period he commenced reading dramatic productions. His protectress recommended him to a company of players in Yorkshire, where he appeared under the name of Carey. Although not more than thirteen years old, he performed the parts of Hamlet, Lord Hastings, and Addison's Cato, well enough to please a provincial audience. In London his talent was applauded by the royal family, a Satan's address to the sun, from Paradise Lost, and the first soliloquy in Shakspeare's Richard III. About this time, he was fortunate enough to attract the attention of doctor Drury, who recommended him to the directing committee of Drury-lane, as there to revive this declining theatre. He was, in consequence, engaged for three years at Old Drury. Kean appeared for the first time on the London boards, Jan. 26, 1814, in the character of Shylock. The first evening was decisive; but his Richard III. made him the idol of the Londoners. In Othello, also, and as Giles Overreach, he has been unequalled by any contemporary. When he performed Massinger's Jew the first time, the actors, and others of his admission,

presented him with a gold cup, as a token of their esteem (June 25, 1814). In 1820, he visited the United States, and performed in New York, Philadelphia, Baltimore, and Boston, on the whole, with great success. A second visit to America, in 1825, was attended with little credit or advantage. His death took place at Richmond, on the 15th of May, 1833. His professional gains in Britain and America, have been estimated at above £150,000; but the recklessness of his character kept him always in difficulties.

KEATS, JOHN; a young English poet, of fine sensibility and great luxuriance of language, was born, of humble origin, in Moorfields, London, on the 29th October, 1796. He was sent to school at Enfield, where he remained till the age of fifteen, and was then bound apprentice to a surgeon; but his inclination to poetry having been cultivated by his teachers at school, he gave way to the ambition of becoming a poet. Keats's first volume of poems, many of which were written in his teens, made its appearance in 1817, when he was in his twenty-first year. This was followed by *Endymion*, a Poetic Romance, in 1818; and, in the year 1820, he published his last and best work, *Lamia*, *Isabella*, and other Poems. Being in feeble health, he was prevailed upon to try the climate of Italy, where he arrived in November, 1820, and died in Rome, on the 27th of December following. His death has been attributed to the attacks of critics; but it was, in fact, owing to a consumptive complaint of long standing. He was interred in the English burying-ground, near the monument of Cains Cestius, and not far from the place where were soon after deposited the ashes of his poetical mourner, Mr Shelley. "Mr Keats," says, Mr Leigh Hunt, who was his earliest and warmest patron, and to whose patronage, as connecting him with the liberal party, may be attributed many of the merciless attacks made on the young poet by Tory writers, "had a very manly, as well as a delicate spirit. He was personally courageous in no ordinary degree, and had the usual superiority of genius to little arts and the love of money. His patrimony, which was inconsiderable, he freely used in part, and even risked altogether, to relieve the wants of others, and further their views. He was handsome, with remarkably beautiful hair, curling in natural ringlets. He had the two highest qualities of a poet in the highest degree—sensibility and imagination. His *Endymion*, with all its young faults, will be a store-house for the lovers of genuine poetry, both young and old, a wood to wander in; a solitude inhabited by creatures of superhuman beauty and intellect; and superabundant in the luxuries of a poetical domain, not omitting 'weeds of glorious feature.' The fragment of *Hyperion*, which was his last performance, and which extorted the admiration of Lord Byron, has been compared to those bones of enormous creatures which are occasionally dug up, and remind us of extraordinary and gigantic times."

KEBIR; an Arabian word, which signifies *large*, and is found in many geographical names.

KEBLA. See *Kaaba*, and *Koran*.

KEDGE, or KEDGER; a small anchor, used to keep a ship steady and clear from her bower anchor, while she rides in a harbour or river, particularly at the turn of the tide, when she might otherwise drive over her principal anchor, and entangle the stock or flukes with her slack cable, so as to loosen it from the ground. The kedge-anchors are also used to transport a ship, or remove her from one part of a harbour to another, being carried out from her in the long boat, and let go by means of ropes fastened to these anchors. They are also generally furnished with an iron stock, which is easily displaced for the convenience of stowing. See *Anchor*.

KEEL; the principal piece of timber in a ship, which is usually first laid on the blocks in building. By comparing the carcass of a ship to the skeleton of the human body, the keel appears as the back-bone, and the timbers as the ribs. The keel supports and unites the whole fabric, since the stem and stern posts, which are elevated on its ends, are, in some measure, a continuation of the keel, and serve to connect and enclose the extremities of the sides by transoms, as the keel forms and unites the bottom by timbers. The keel is generally composed of several thick pieces placed lengthways, which, after being scarfed together, are bolted and clinched upon the upper side.

*False Keel*; a strong, thick piece of timber, bolted to the bottom of the keel, which is very useful in preserving its lower side. The false keel is provided when the thick pieces which form the real keel cannot be procured large enough to give a sufficient depth thereto. In large ships of war, the false keel is composed of two pieces, called the *upper* and *lower* false keels. The lowest plank in a ship's bottom, called the *garboard streak*, has its inner edge let into a groove or channel, cut longitudinally on the side of the keel: the depth of this channel is therefore regulated by the thickness of the garboard streak.

KEEL-HAULING; a punishment inflicted for various offences in the Dutch navy. It is performed by suspending the culprit by a rope from one yard-arm, with a weight of lead or iron upon his legs, and having another rope fastened to him, leading under the ship's bottom, and through a block at its opposite yard-arm. He is then suddenly let fall from the one yard-arm into the sea, where, passing under the ship's bottom, he is hoisted up on the opposite side of the vessel to the other. This punishment is not altogether unknown in British ships; but, as it is dangerous, it is very rarely, or, indeed, scarcely ever now practised.

KEELSON, or KELSON; a piece of timber forming the interior or counterpart of the keel, being laid upon the middle of the floor timbers immediately over the keel, and serving to bind and unite the former to the latter, by means of long bolts driven from without, and clinched on the upper side of the keelson. The keelson, like the keel, is composed of several pieces scarfed together; and, in order to fit with more security upon the floor timbers and crotchets, it is notched about an inch and a half deep, opposite to each of those pieces, thereby scored down upon them to that depth, where it is secured by spike-nails. The pieces of which it is formed are only half the breadth and thickness of those of the keel.

KEENERS; the name of the Irish singing mourners. The Irish have always been remarkable for their funeral lamentations, and once were celebrated for their musical art, in the last sad offices to their departed friends. Formerly, these duties were performed by dressing the body of the deceased in grave-clothes, ornamenting it with flowers, and placing it on a bier; when the relations and keeners, ranging themselves in two divisions, one at the head and the other at the feet of the corpse, the chief bard of the head chorus, softly accompanied by the harp, sung the first stanza of the *caoinan*, or funeral song. This being ended, the foot semi-chorus began the lamentation, or *ullaloo*, in which they were answered by the head semi-chorus, and then both united in one general chorus. After this, the chief bard of the foot semi-chorus began the second *gol*, or lamentation, in which he was answered by that of the head; and then, as before, both united in the general full chorus. Thus, alternately, were the song and choruses solemnly performed during the night. But whatever

merit or decorum there might formerly be in these vocal obsequies of the Irish, they have, at present, little to boast, either of melody, harmony, or dignity. The keepers now generally consist of a motley multitude of men, women, and children, and the *caoinan* is degenerated into a wild and hideous howl.

**KEEP**, in ancient military history; a kind of strong tower, which was built in the centre of a castle or fort, to which the besieged retreated, and made their last efforts of defence. It is also called the *donjon*, or *dungeon*.

*To keep*; a term used, on several occasions, in navigation; as, *to keep the land aboard*, is to keep within sight of land as much as possible.—*To keep the luff*, or *the wind*; to continue close to the wind; i. e. sailing with a course inclined to the direction of the wind as much as possible.—*To keep off*; to sail at a distance from the shore or a ship, &c.

**KEEPER OF THE GREAT SEAL** (see *Chancellor*, *Lord High, of England*; for the office and privileges of the French keeper of the seals (*garde des sceaux*), before the French revolution of the last century, (see *Chancellor*). The *garde des sceaux*, or keeper of the seals, in France, is at present always minister of justice. On the continent of Europe, the department of justice is directed in the same way as the finances, &c., at the head of which stands a *chef*, or minister.

**KEEPER OF THE PRIVY SEAL**, in England, is a lord by virtue of his office, through whose hands pass all charters signed by the king, before they come to the great seal.

**KEEPER OF THE KING'S CONSCIENCE**. See *Chancellor*.

**KEEPER, BOAT**, one of the boat's crew who remains as a sentinel, in his turn, to take care of the boat and her contents when she is ashore, or alongside of a ship, or is towed astern of her.

**KEEPING**, in painting, is a technical term, which signifies the peculiar management of colouring and *chiaro oscuro*, so as to produce a proper degree of *relievo* in different objects, according to their relative position and importance. This may be effected either by shade or colour, either by throwing a shadow across the inferior objects, or by tinting them with a colour less bright than that given to others, and, in very skilful hands, it may even be done by the directly reverse practice. As the objects recede in the ground plane, the hue of the atmosphere, intermixing with their *proper* or *local* colour, as it is termed, will assist in their keeping. On keeping, *relievo* entirely depends; for, if the lights, shadows, and half tints be not kept in their exact relative proportions of depths, no rotundity can be effected, and, without due opposition of light, shade, and colours, no apparent separation of objects can take place. The celebrated Raphael has, in two instances, totally failed of proper keeping—in the Transfiguration, and the miraculous Draught of Fishes.—The word *keeping* is also sometimes used of works in other branches of the fine arts, as of a drama, to denote the just proportion and relation of the various parts.

**KEHL**; a village in the grand duchy of Baden, formerly a fortress of the German empire, situated at the influx of the Kinsig into the Rhine, over which there is a bridge to Strasburg, about two miles distant. The fortress was built by the French, towards the end of the seventeenth century, and was intended to aid Louis XIV.'s plans of conquest on the right bank of the Rhine. By the peace of Ryswick, in 1697, Kehl was ceded to the margrave of Baden-Baden, the empire retaining the right to garrison it. In the middle of the last century, the fortifications were demolished, and Kehl became the

seat of manufactures. Here Beaumarchais established his printing press, from which proceeded an edition of Voltaire and other magnificent editions. During the revolutionary war, the fortifications were rebuilt. Kehl has sustained several sieges (the severest in 1796), has been alternately in French and German hands, and has been three times burnt down. In 1806, it was included in the department of the Lower Rhine; in 1814, it was restored to Baden. In 1815, the works were again demolished. It has about a thousand inhabitants.

**KEISER**, one of the earliest German opera composers, born at Leipsic, in 1673, died 1739. He left 118 operas, besides much church-music, full of originality, and distinguished by a noble and pure style. Being, besides, self-formed, he deserves to be ranked among the first composers.

**KEITH, JAMES**; a brave and experienced warrior, as well as an able and successful politician, field-marshal of Prussia, and the confidential friend of a sovereign. He was descended of a noble house in Scotland, being the youngest son of William Keith, earl-marshal of that kingdom, and was born in 1696. The breaking out of the rebellion, in 1715, developed his military propensities, and gave the future colour to his fate. His mother, warmly attached to the house of Stuart, added her persuasions to the dictates of his own inclination, and, at the age of nineteen, he joined the Pretender's standard. The issue of the battle of Sheriffmuir, so unfortunate to the cause he had embraced, drove him into voluntary exile: he escaped from the conflict wounded and with difficulty, and effected a retreat to France. Here he applied himself with great diligence to the study of mathematics and military tactics, having previously made considerable progress in classical and general literature, under the auspices of the celebrated Ruddiman. In 1717, he quitted Paris for Italy, whence he proceeded to Spain, in the capital of which kingdom he was fortunate enough to obtain the friendship of the duke of Liria, who procured him a command in Ormond's Irish brigade. He subsequently accompanied his patron, when appointed ambassador to Russia, where, through the duke's recommendation, he obtained the rank of lieutenant-general from the czarina, who also conferred on him the order of the black eagle. In the Russian service, he continued several years, distinguishing himself as well in the field as in the cabinet, during the war with Turkey and Sweden. In the revolution which ended by the elevation of the czarina Elizabeth to the throne, he also took a prominent part; but, at length, on some disgust, he obtained his dismissal. On leaving Russia, he went to Berlin, where the king of Prussia, to whom his abilities were well known, received him with open arms, and raised him to the post of governor of his metropolis, and field-marshal of his forces. He made him also his confidential companion, selecting him as his associate in a tour which he made incognito through part of the north of Europe. In the subsequent wars of that martial monarch, field-marshal Keith continued to display the greatest military talents as well as zeal in his service, till his career was finally closed by a cannon-shot, in the unfortunate battle of Mollath-Kirchen, October 14, 1758.

**KELLER, JOHN BALTHASAR**, was born at Zurich, and studied the art of casting in metal, during the most flourishing time of Louis XIV. Keller was distinguished himself by the boldness with which he undertook to cast the most important works. Towards the end of the seventeenth century, Giovanni made the model of an equestrian statue of the king, twenty-one feet high. The statues of Marco Aurelius, Cosmo de' Medici, Henry IV. and Louis

XIII. had been cast in several pieces; but Keller undertook to cast the statue of the king in one piece. The work was successful, and did as much honour to Keller as to Girardon. The king rewarded him, and gave him the direction of the foundry of the arsenal. He died in 1702. His brother, John James Keller, born 1635, was likewise a skilful founder. He died at Colmar, in 1700.

KELLERMANN, duke of Valmy, marshal and peer of France, born at Strasburg in 1735, entered the Coudans legion as a hussar, in 1752, and performed in it the first campaigns of the seven years' war. He went through all the degrees of service, up to the rank of *maréchal de camp*. At the breaking out of the revolution, he so distinguished himself by patriotism and judgment, that the citizens of Landau, in the garrison of which he was stationed, presented him with a civic crown. At the commencement of the war, he received the command of the army of the Moselle, formed a junction, in September, with the main army under Dumouriez, and sustained, September 20, 1792, the celebrated attack of the duke of Brunswick. This cannonade of Valmy, as it is called, caused the allies to retreat, and perhaps decided, not merely the whole campaign, but also the fate of Europe, and the supremacy of France, till 1813. In the following wars of France, Kellermann received various general commands. Napoleon loaded him with honours, and gave him *Johannisberg*. After the restoration of the Bourbons, he was appointed a member of the chamber of peers, where he espoused the liberal side. He died September 12, 1820, eighty-five years of age. In his last will, he had ordered that his heart should be buried on the field of Valmy.

KELGREN, HENRY, a Swedish poet and *savant*, was born in 1751, in Schonen, and studied at the university of Abo. Gustavus III. protected him against the assaults of envy in Stockholm, and put him beyond the reach of want. He was one of the first members of the academy of sciences, established by the same monarch, at Stockholm. Kelgren's assiduous study was too much for his weak frame. He died in the Swedish capital, in 1795. On his tombstone are the words *Poeta, philosopho, civi, amico legentes amici*. He is considered as a poet of a very rich imagination. His complete works appeared after his death at Stockholm. As editor of the literary part of the Stockholm Journal, he laboured much to improve the taste of his countrymen, and his criticisms made him many enemies.

KELP, in commerce; the ashes of sea-weeds or *fuci*. See *Fucus*. *F. serratus* and *F. vesiculosus*, the species used in the manufacture of this article, grow attached to rocks between high and low water mark, and are often termed *rock-weed*. On the Scottish coast, the sea-weed is cut close to the rocks, during the summer season, and afterwards spread out upon the shore to dry, care being taken to turn it occasionally, to prevent fermentation. It is then stacked for a few weeks, and sheltered from the rain, till it becomes covered with a white saline efflorescence, and is now ready for burning. This is usually accomplished in a round pit, lined with brick or stone; but the more approved form for a kiln is oblong, about two feet wide, eight to eighteen long, and from two to three deep; the bottom of this is covered with brush, upon which a little dried seaweed is scattered, and fire is applied at one extremity; the sea-weed is now thrown on gradually, as fast as the combustion reaches the surface, and should there be much wind, it is necessary to protect it by covering the sides with sods; after the whole is burnt, the mass gradually softens, beginning at the sides, when it should be slowly stirred up with a heated iron

bar, and incorporated, till it acquires a semi-fluid consistence. This part of the process requires considerable dexterity; and, if the mass continues dry, a little common salt should be thrown on, which acts as a flux. When cold, it is broken up, and is now ready for sale.

During the war, and for some time after, when barilla and salt were highly taxed, kelp was manufactured to a large extent in Ireland and Scotland, but more particularly in the Hebrides, where it was a source of support to many of the poorer inhabitants. In Scotland and its isles alone, the total quantity annually made amounted to about 20,000 tons annually, the average price of which was £10 9s. 7d. per ton. But with the reduction of the duties on barilla and salt, this trade was totally ruined, and shores that formerly yielded the proprietors a rent of from £200 to £500, are now worth nothing. It was the repeal of the duty on salt that mainly put a stop to the kelp manufacture. The purification of kelp for soap-making is more troublesome and expensive than the decomposition of salt, and the greater quantity of alkali used is now obtained by the latter method. Even with the reduction of the duty on barilla, kelp might still have been manufactured, though with less profit, but for the repeal of the duty on salt.

One of the products of kelp, we have not yet adverted to, is iodine. (q. v.) The uses of soda are, in general, the same with those of potash, but there are certain branches of manufactures to which it is indispensable, as to the making of plate and crown-glass, and all hard soaps. Both alkalies are consumed in immense quantities by soap-boilers, bleachers, and glass-makers; but it is said that in France the use of potash has very much diminished since the culture of barilla has been introduced. The barilla obtained in France from the *salicornia annua* yields fourteen or fifteen per cent. of soda; and that from *salsola tragus*, *S. kali*, *statice limonium*, *atriplex portulacoides*, &c., yields only from three to eight per cent. The Spanish barilla is the most esteemed, particularly that from Alicante, and is obtained from the *salsola sativa*, which is carefully cultivated in light, low soils, embanked on the side next the sea, and furnished with flood-gates, through which the salt water is occasionally admitted. So anxious are the Spaniards to monopolise this trade, that the exportation of the seed is prohibited under pain of death. (See *Barilla*.) Carbonate of soda is also found abundantly in a mineral state in many countries, as in Hungary, the southern parts of Siberia, Persia, China, North Africa, and the environs of Smyrna; but the native salt has not hitherto become important as an article of commerce.

KELSO, a town of Scotland, in Roxburghshire, situated on the north bank of the Tweed, forty-two miles S. E. of Edinburgh. It was anciently called Calc-How and Calco, from the calcareous hill still conspicuous in the town, and termed the Chalk Heugh, owed much of its ancient importance to the stately abbey, founded in 1128, to the honour of the virgin Mary and St John, by the earl of Northumberland, afterwards David I., for a mitred abbot and monks of the order of Tyronenses, whom he first settled at Selkirk, then at Roxburgh, and finally fixed here, granting them many valuable privileges, with an endowment so liberal, that at the suppression it is stated to have been worth £2000 Scotch per annum. A considerable portion of this once-extensive and sumptuous edifice remains, exhibiting a most interesting specimen of the Norman style; and that fine taste in sacred architecture by which it is distinguished. The town was thrice destroyed by fire during the border warfare, was burned down by accident in 1686, and a like casualty caused its almost entire destruction

again in 1745, from which period it has gradually arisen to its present state, that of a well-built, gay, and populous place. It is delightfully seated on the northern bank of the river Tweed, which is crossed by a noble bridge of five arches, built upon the site of a more ancient structure that was swept away by a flood in 1798; there is also a bridge over the Tiviot, which, running from the southward, forms a junction with the Tweed, nearly opposite to the town. Almost at the southern termination of the principal street, which runs parallel with the Tweed, is the market-place, containing many handsome buildings and shops; and on the east side of it is a newly-erected town-house, comprising the town-hall and other public offices, with piazzas, and an arcade underneath, for the convenience of the great concourse of persons who resort to the high markets, of which there are twelve in the year (exclusive of the weekly marts), viz., two before, and one after the Whitsuntide and Martinmas terms, for hiring servants, and the other six in March and at the close of autumn, chiefly for horses. This is often the seat of the Caledonian hunt; and the Kelso races are held upon Cavertown Edge, a muir in the adjoining parish of Eckford. The parish church, which is dedicated to the virgin Mary, stands at the east end of the venerable abbey, a conspicuous ornament to the place; there are also an elegant episcopal chapel, burgher, anti-burgher, and relief meeting-houses, three benefit societies, a public dispensary, three subscription libraries, containing valuable collections of books, two public schools of some repute, one for Latin, the other for English; with several minor establishments for the instruction of youth, including a school of industry, conducted on a plan most creditable to its originators. The inhabitants are mostly employed in the manufacture of woollen cloth, linen, stockings, shoes, leather, and in the dressing of sheep and lamb skins, the latter business being carried on to a considerable extent for the supply of the populous country, of which Kelso is the centre. Population, in 1831, 4939.

**KEMBLE, JOHN PHILIP:** one of the most eminent tragedians of the British stage, was the eldest son of Roger Kemble, manager of a company of comedians at Prescot in Lancashire, in which county he was born, February, 1757, and received the rudiments of education at the Roman Catholic seminary of Sedgley park, Staffordshire. With the view of qualifying him for one of the learned professions, he was afterwards placed by his father at the college of Douay, where he early distinguished himself by his proficiency in elocution. On his return to England, having completed his academical pursuits, he entered immediately upon the profession of an actor, for which he had long exhibited a decided predilection. At this period, he produced a tragedy on the story of Belisarius, which was acted at Liverpool, and printed a volume of Fugitive Pieces, in verse, with which he was, however, so dissatisfied, that, on the day after their publication, he destroyed every copy he could recover. Mr Kemble appeared, for the first time in London, on the Drury-lane boards, September 30, 1783, in the part of Hamlet, and was received with great applause. It was not, however, till the retirement of Smith from the stage, in 1788, that he took a decided lead in tragedy. He afterwards obtained the management of Drury-lane theatre, which he enjoyed with only a short interruption, till 1801. In 1794, he brought out a musical entertainment of his own, entitled *Lodoiska*, which had a great run, and has since been revived with benefit to the theatre. In 1802, he visited the continent, and having passed twelve months at Paris and Madrid, returned to London, when he pur-

chased a sixth share in the Covent-garden theatre, and became manager of that establishment. Here he continued his career with great success, till the destruction of the theatre by fire in 1809. In the autumn of the same year, the present edifice, being constructed, opened with an increase of price, which, together with certain obnoxious arrangements in regard to the private boxes, created, for a series of nights, the disturbances known by the name of the *O P riots*. Mr Kemble took his farewell of the stage July 23, 1817, on which occasion he was complimented with a public dinner and other honorable tokens of esteem, and shortly after retired to the continent, where he died at Lausanne, in Switzerland, February 26, 1823, of a paralytic attack, after a few hours' illness. As an actor, Kemble was distinguished for dignity, precision, and studious preparation. His merits were differently appreciated, but by all he was regarded as a highly gifted actor, and the impression which he made in characters more immediately adapted to his style of excellence, such as Cato, Coriolanus, Hamlet, John, Jacques, Paraddock, was very great. His management both of Drury-lane and Covent-garden theatres, but especially of the latter, was also marked by the exhibition of much refined and accurate taste, in the rectification of scenic decoration, and the adoption of appropriate costume, adding thereby both to the splendour and illusion of the drama. The learning, elegant manners, and accomplishments of Mr Kemble introduced him into the best company, by whom he was at once courted and esteemed. See *Boaden's Life of Kemble*.

**KEMPELEN, WOLFGANG, BARON VON,** famous as the inventor of the automaton chess-player, was a native of Presburg in Hungary. He displayed much talent, when young, as a mechanic; and, as early as 1769, he announced the completion of his automaton or androïde, which has since attracted so much attention. In 1783, the chess-playing figure was first exhibited at Paris; and it afterwards made its appearance in London, where it surprised and puzzled those who witnessed its performance. Baron Kempelelen or his assistant was always present, to direct, by some incomprehensible method, the motions of the machine. It consists of a figure in a Turkish dress, seated at a table, the top of which is marked as a chess-board. The arm of the automaton, by means of internal machinery, is capable of executing about a dozen motions, which it appears to perform spontaneously, so as to play a game at chess with any visitor. While the movements are taking place, the noise of a fly-wheel is heard; and, after a certain time, the machinery requires winding up like a clock, before it can again be brought into action. Various conjectures have been advanced as to the means by which the action of this machine is directed. The most probable of which is, that a child or small man is concealed in a drawer under the table which supports the chess-board. It is true that the whole cavity beneath the table, as well as the body of the figure, is opened and exhibited to the spectators previously to the commencement of an exhibition; but as the inside of the automaton and the space under the table are not shown at the same time, an individual within might move from one part to the other, so as to deceive those who witness the performance. It is easy to conceive that, by means of some audible signal, the evolutions of the automaton may be directed. This very ingenious man also constructed a speaking figure, of which he published an account in a curious work, entitled *La Mécanisme de la Parole, suivi de la Description d'une Machine parlante, et enrichi de 36 Planches* (Vienne, 1791, 8vo.) also printed in Ger-

men. He contrived, likewise, a printing-press, for the use of *mademoiselle Paradies*, a famous blind musician. He also published German poetry; a drama, called *Perseus and Andromeda*; the *Unknown Benefactor*, a comedy, &c. He died at Vienna in 1804. The chess-player is now in the possession of Mr Malsel, who has himself invented several ingenious automata, which, together with the chess-player, have been publicly exhibited.

KEMPIS, THOMAS A. See *Thomas à Kempis*.

KEN, THOMAS, a learned and pious dignitary of the English church, was educated at Oxford. About 1679, he went to Holland to officiate as chaplain to the princess of Orange, and afterwards to Tangier, as chaplain to the earl of Dartmouth. In every station which he held, he exhibited a conscientious propriety of conduct and unyielding morality, which procured him the respect of the licentious court of Charles II., and, strange as it may appear, conciliated the favour of that profligate prince; for, residing at Winchester when the king, attended by his female favourites, visited that city, his house was designed by his majesty's harbinger for the lodging of Nell Gwynn; but doctor Ken, thinking such an inmate unsuitable for a man of his function, positively refused to admit her. When the king was informed of his conduct, he coolly said, "Mrs Gwynn must find lodgings elsewhere; and, to the surprise of his courtiers, he took the first opportunity to promote this conscientious supporter of the dignity of his character. Doctor Ken became a chaplain to Charles II., in whose reign he was made bishop of Bath and Wells. He was one of the seven bishops sent to the Tower for resisting the dispensing power claimed by king James, and for petitioning in behalf of their own and the people's rights. After the revolution, bishop Ken refused to take the oath of allegiance to king William, in consequence of which he was deprived of his preferment. He was, however, highly respected by those of opposite sentiments, and queen Anne bestowed on him a pension. He died in 1711. His works, consisting of sermons, poems, &c., were published in 4 vols. 8vo., 1721, with an account of his life.

KENAWHA, or KENHAWA, GREAT; a river in Virginia, which has its sources in the western part of North Carolina, flows through the western part of Virginia, in a north-westerly direction, and joins the Ohio at Point Pleasant, eighty-seven miles below Marietta, and 265 below Pittsburg. It receives Green Brier river in the western part of Monroe county, and, about forty miles below the junction, it has a remarkable cataract, falling perpendicularly fifty feet. There are salt-works on the river, a little above the town of Charleston. The river is navigable most of the year.

KENAWHA, LITTLE; a river of Virginia, which runs west into the Ohio, 178 miles below Pittsburg.

KENILWORTH (called, by corruption, *Killingworth*); a town in Warwickshire, England, five miles N. of Warwick, six S. S. W. of Coventry, and 61 N. W. of London. Population, in 1831, 3097. It consists chiefly of an irregular street, nearly a mile in length, and has considerable manufactures of iron combs, and a market on Wednesday. The town is chiefly noted for its magnificent castle, which, long with its extensive chase and park, formed at one time the pride and ornament of this part of the kingdom. It was originally founded by Geoffrey de Clinton, chamberlain and treasurer to Henry I. Most of the buildings, of which remains are yet visible, were erected by John of Gaunt, father of Henry IV. continued in the possession of the crown till the reign of Elizabeth, who conferred it on Robert Dudley,

earl of Leicester. He enlarged and adorned it at the expense of £60,000, and afterwards entertained the queen here for seventeen days, in a style of extraordinary magnificence. The area within the walls of the castle contained seven acres, and the circuit of the walls, manors, parks and chase, was nineteen or twenty miles. The building was greatly injured during the civil wars; and the remains of the castle now present one of the most splendid and picturesque wrecks of castellated strength in England, and impart a melancholy grandeur to the town and neighbourhood. The romance of Sir Walter Scott has given it additional interest.

KENNEBEC; the largest river in Maine, after the Penobscot. It has two principal branches—the eastern and western. The former rises from Moosehead lake; and the latter, called *Dead river*, interlocks with the sources of the *Claudiere*, with which it is connected by a portage of only five miles. The two branches unite about twenty miles below Moosehead lake, and the river afterwards pursues a southerly course. It is joined by the *Androscoggin* eighteen miles from the sea. The tide flows up as far as Augusta, and the river is navigable for ships to Bath, twelve miles, for vessels of 160 tons to Hallowell, forty miles, for sloops to Augusta, two miles farther, and for boats to Waterville, eighteen miles above Augusta. There are a number of handsome and flourishing towns on the river, among which are Bath, Gardiner, Hallowell, Augusta.

KENNICOTT, Doctor, and professor of theology at Oxford, born in 1718, at Totness in Devonshire, where his father was a poor shoemaker and sexton, has become known by his extensive and valuable collection of readings from about 580 manuscripts, and twelve printed editions of the Hebrew Bible, which he annexed to his edition of the Hebrew text. This work is entitled *Vet. Test. Hebr., cum variis Lectionibus* (2 vols., fol., Oxford, 1776—80). To the 2d volume is prefixed a *Diss. gener. in V. T. Hebr.* In this laborious and expensive undertaking, Mr Kennicott was assisted by a subscription of several thousand pounds, and thus enabled to send several scholars to Spain, Italy, Germany, &c., to collate manuscripts and editions. The work has many typographical errors. The author's plan, too, was defective, and he was not sufficiently acquainted with the Eastern languages and the true principles of criticism; but he rendered great service to the cause of science and religion by opening the way in this department of biblical criticism. At the time of his death, he was employed in preparing Remarks on select Passages in the Old Testament, which were subsequently published, accompanied by eight sermons.

KENSINGTON; a large and populous village of England, in the county of Middlesex, nearly two miles from Hyde-park corner, and chiefly distinguished for its royal palace and gardens. In former times, Kensington palace was a favourite royal residence: and king William III., queen Mary, queen Anne, and George II., died here. Kensington gardens, attached to the palace, are well known, and much frequented as a fashionable promenade in summer. They form a great ornament to the metropolis. These gardens contained originally twenty-six acres, and twenty acres were added by queen Anne. Population, in 1831, 20,902.

KENT; a maritime county of England, forming the south-eastern angle of the island of Great Britain, whence, probably, originates its name, the word *Cant* signifying a corner, in the ancient Gaulish, or Celtic dialect. It is bounded on the north by the river Thames, which divides it from Essex; on the west by Surrey and Sussex; on the south by the English Channel; and on the east by the German Ocean. It

contains numerous monuments of antiquity, and has been the theatre of many important events connected with our national history. On the eastern coast the Romans landed, under Julius Cæsar, when he invaded Britain, 54 B. C. and again the following year; but he made no permanent conquest, and a century elapsed before this part of the island submitted to the power of Rome, when Kent became a part of the province called *Britannia Prima*. In this county the Saxons, commanded by Hengist and Horsa, obtained their earliest settlements, having been invited hither by the Britons, to aid them in repelling the invasions of the Picts and Scots, but becoming ultimately much more formidable enemies than those northern marauders. An open war at length took place between the Britons and their former allies, and Hengist, having subdued this county, about 455, assumed the title of king of Kent. Canterbury was the capital of this kingdom, and Ethelbert, who reigned here towards the close of the sixth century, having been converted to Christianity by Augustin, an Italian monk, founded in that city the first bishopric among the Anglo-Saxons, in consequence of which, when other sees were founded, this was made an archbishopric, and the prelates who sat here became primates of all England, which ecclesiastical dignity they still retain. When the kingdoms of the Heptarchy were united under the sovereignty of the West Saxon princes in the ninth century, Kent, from its vicinity to London, and other local advantages, retained much of its former importance; and William, duke of Normandy, after his victory over the English, near Hastings, is said to have entered into a convention with the people of Kent, securing unto them their ancient rights and privileges, as the condition of their admitting his claim to the crown; and hence it is supposed the custom of gavelkind has been preserved in this county, while it has been abolished in almost every other part of England. At a subsequent period William appears to have shown his conviction of the maritime importance of Kent, by the institution of the cinque-ports, a measure which probably had a considerable effect in promoting the naval prosperity of Britain.

The surface of this county displays much diversity of scenery, the banks of the Thames being low and marshy, while the central and eastern parts consist of a range of chalk hills, terminating in the white cliffs of Dover; and that portion bordering on Sussex, called the Weald of Kent, is a flat woody tract, of a clayey soil, fruitful, but damp and unhealthy, especially at the southern angle, where its extremity forms the great marsh of Romney. The western districts include hill and dale, arable and pasture land, equaling in pleasantness and variety of products the most agreeable and fertile parts of the kingdom. Two chains of hills intersect this county, termed the Upper and the Lower Hills; the former, situated to the north, are the chalk hills already mentioned, in which are embedded numerous nodules of flint, and fossilised organic remains; the southern or lower range, consists of iron-stone and rag-stone; and on the west, towards Surrey, a mixture of clay and gravel predominates. Kent is watered by several rivers, the most considerable of which, next to the Thames, is the Medway, formed by four streams, which unite near the confines of Sussex, and passing by Maidstone and Rochester, this river expands into an estuary, containing several small islands, and joins the Thames at Sheerness. The Stour rises in the Weald of Kent, flows by Canterbury, and falls into the sea north of Sandwich; the Rother which has its source in Sussex, forms the boundary between that county and Kent, and empties itself into the sea at Rye; and the Ravensbourn, the Cray, and the

Darent mingle their waters with the Thames. Besides the usual productions of agriculture, Kent affords large quantities of hops, by which the brewers of the metropolis are principally supplied. Here also are grown various kinds of fruit, especially cherries and apples, for the Loudon market. Population, in 1831, 479,155.

KENT, EDWARD, duke of, fourth son of George III., king of Great Britain, was born Nov. 2, 1767. He was educated in England, at Göttingen, and Geneva, where he remained until 1790; when he proceeded in a military capacity to Gibraltar. He subsequently went to America, and, in 1796, became lieutenant-general, and returned to England. In 1799, he was created duke of Kent and Strathearn and earl of Dublin, and the same year visited America, but returned again in 1800. In 1802, he was made governor of Gibraltar; but his rigid discipline produced a mutiny, and he was recalled the following year. In 1818, he married the youngest daughter of the duke of Saxe-Coburg, and the widow of the prince of Leiningen. In May, 1819, the duchess bore him a daughter, who was called Alexandra Victoria, who is now heiress presumptive of the crown. The duke of Kent died Jan. 23, 1842. His widow, with her brother, prince Leopold, the husband of the late princess Charlotte, at present assumes the principal guardianship of the princess, who is likely to become the future sovereign of Great Britain.

KENT, WILLIAM, an ingenious artist, was born a Yorkshire, in 1685. He was apprenticed to a coach-painter, but, conscious of superior talent, repaired to London, where he was enabled, by some gentleman, to repair to Rome, and to study painting under cavalier Luti. In this art, however, he never obtained celebrity: his talent lay chiefly in ornamental architecture, some specimens of which at Holkham, Stowe, and other places, are much admired. He is regarded by Horace Walpole as the inventor of modern gardening, which he rendered more natural, graceful, and pleasing. He leaped the sunk fence, says the last-mentioned writer, and saw that all nature was a garden. He broke up the old uniformity of straight lines and corresponding parts, and threw wind, water, and ground, into the beautiful shapes presented by nature. The taste of Pope is supposed to have aided that of the artist. He died at Burlington-house in 1748, aged sixty-three, and was buried at Chiswick.

KENTUCKY; one of the United States of America, bounded north by the river Ohio, which separates it from Ohio, Indiana, and Illinois, east by Virginia, south by Virginia and Tennessee, and west by the river Mississippi; lon. 81° 50' to 89° 20' W. lat. 36° 30' to 39° 10' N.; 300 miles long, and from 80 to 180 broad; square miles, 42,000; population, in 1790, 73,677; in 1800, 220,959; in 1810, 406,311; in 1820, 564,317; and in 1830, 688,844; free white persons, 518,678; free coloured persons, 4816, and slaves, 165,350. The first permanent settlement in Kentucky was begun by colonel Daniel Boone, in 1775. The country formed a part of the state of Virginia until 1790; in 1792, it was admitted into the union as an independent state. Frankfort is the seat of government. Lexington and Louisville are the largest towns. There is a penitentiary at Frankfort, in which are confined over 100 convicts. At Lexington, there is a lunatic asylum; at Danville an asylum for the deaf and dumb; and at Louisville and Smithland on the Ohio, hospitals for sick and disabled boatmen. The most prominent literary institution is Transylvania university, at Lexington, which has about 150 students, besides the students of the law and medical schools, and of the frequent

tory department. There is a Roman Catholic college at Bairdstown, called St Joseph's college; Centre college, at Danville, established by Presbyterians; and a college at Augusta, established by Methodists. There is also a Baptist college at Georgetown, and a Presbyterian college, called Cumberland college, at Princeton. The legislature has several times taken steps for establishing a system of common schools, but nothing effectual has been accomplished. There are two banks in the state, called the bank of Kentucky, and the bank of the commonwealth. There are also branches of the United States bank at Lexington and Louisville. The legislature is composed of a senate, consisting of thirty-eight members, chosen by districts, for four years, and a house of representatives, not exceeding 100, chosen annually. The governor and lieutenant-governor are chosen by the people for four years, but are not eligible for the succeeding seven years. The legislature meets on the first Monday in November. The principal rivers of Kentucky are the Ohio, which flows along the state 637 miles, following its windings; the Mississippi, Tennessee, Cumberland, Kentucky, Green, Licking, Big Sandy, Salt and Rolling. The Cumberland mountains form the south-east boundary of this state. The eastern counties, bordering on Virginia, are mountainous and broken. A tract from five to twenty miles wide, along the banks of the Ohio, is hilly and broken land, interspersed with many fertile valleys. Between this strip, Green river, and the eastern counties, lies what has been called the garden of the state. This is the most populous part, and is about 150 miles long, and from 50 to 100 wide. The soil is excellent, and the surface is agreeably diversified, gently rising and descending. These lands produce black-walnut, black-cherry, honey-locust, buckeye, pawpaw, sugar-maple, mulberry, elm, ash, cottonwood, whitethorn, with an abundance of grape-vines. There is a tract of country in the south-western part of the state, east and north of Cumberland river, and watered by Green and Barren rivers, about 100 miles in extent, called the *barrens*, which, a few years since, was a beautiful prairie, destitute of timber. It is now covered with a young growth of various kinds of trees. These, however, do not prevent the growth of grass, and an almost endless variety of plants, which are in bloom during the whole of the spring and summer, when the whole region is a wilderness of the most beautiful flowers. The soil is of an excellent quality, being a mixture of clay, loam, and sand. Through this country there runs a chain of conical hills, called *knoles*. It is also distinguished for some stupendous caves. Ancient fortifications and mounds of earth are found in almost all parts of Kentucky. The caves in the south-western part of the state are great curiosities. One, styled *Mammoth cave*, 130 miles from Lexington, on the road leading to Nashville, is said to be eight or ten miles in length, with a great number of avenues and windings. Earth strongly impregnated with nitre is found in most of these caves, and there are many establishments for manufacturing it. From 100 pounds of earth, 50 pounds of nitre are frequently been obtained. A number of the rivers in this state have excavated the earth, so as to form abrupt precipices, deep glens, and frightful falls. The precipices formed by Kentucky river are, in many places, awfully sublime, presenting perpendicular banks of 300 feet, of solid limestone, surrounded with a steep and difficult ascent, four times as high. The banks of Cumberland river are less precipitous, but equally depressed below the surface of the surrounding country. Wheat, tobacco, and hemp are the staple productions. Indian corn is, however, the principal grain raised for home con-

sumption. Rye, oats, barley, buckwheat, flax, potatoes, &c., are cultivated. Apples, pears, peaches, cherries, and plums are the most common fruits. The domestic animals are large and beautiful, particularly the horse. Great numbers of swine, horned cattle, horses, and mules are annually driven to the neighbouring states for a market, and large quantities of pork, bacon, and lard are exported. The fattening of animals is the chief mode of consuming the surplus grain, on account of the expense of conveying it to market. Considerable quantities of whiskey are made. Marble, of excellent quality, abounds, and the whole state may be said to repose on a bed of limestone. Salt and iron are among the minerals of this state. The most extensive works for the manufacture of salt established west of the Alleghany mountains, are on the waters of Kentucky. These supply not only this state, but a great part of Ohio and Tennessee. Kentucky, from its position, has become a manufacturing state. See *United States*.

*Kentucky*; a river in Kentucky, which rises in the south-east part of the state, and runs north-west into the Ohio, seventy-seven miles above the rapids at Louisville. It is navigable, in the winter, for small boats, about 180 miles. The current is rapid, and the banks are high and rocky.

KEPLER, JOHN, a great mathematician and astronomer, to whom astronomy is indebted for much of its present perfection, was born in 1571, at Weil, in Wurtemberg, and was descended from a noble family. Poverty, and the vicissitudes of his father's fortune (who was an innkeeper), were the causes of the neglect of his education, and of the unhappiness of his youthful days. But, in his eighteenth year, after the death of his father, he left the monastic school of Maulbrunn, and succeeded in entering the university of Tubingen. Here he studied the course then prescribed—first philosophy and mathematics, and then theology. He also indulged his inclination for astronomy, and devoted himself especially to the investigation of the physical causes of the motion of the celestial bodies. From Tubingen, he was invited, in 1593, to become professor of mathematics and morals at Gratz, in Stiria, where he pursued his astronomical studies. For the sake of freedom of conscience, he fled to Hungary, but returned some time after. Meanwhile the astronomer Tycho de Brahe had come to Germany, his acquaintance with whom had an important influence on Kepler's life. He resolved to relinquish his situation, and to prepare, at Prague, with Tycho, the famous Rodolphine tables, called after the reigning emperor Rodolph, which were first printed at Ulm, in 1626, and which Lalande (*Ast. i. p. 474*) calls an *Ouvrage essentiel, et qui fut le fondement de tous les calculs de l'astronomie pendant un siècle*. At Tycho's recommendation, he was established in that place; but, as his office and science did not afford him a subsistence, he studied medicine, in order to gain a livelihood by the practice of it. The emperor had assigned him a salary, but, in the period of trouble which preceded the thirty years' war, it was not paid. Even when he was appointed imperial mathematician, by Rodolph's successor, Matthias, his hope of recovering his arrears was disappointed. Controversies with the clergy, and the disturbed state of the Austrian dominions, made his situation very uncomfortable. He left Lintz, repaired to Ratisbon, declined an invitation to England, and was confirmed by the succeeding emperor, Ferdinand, in the office of imperial mathematician, and afterwards went to Ulm, in order to print his Rodolphine tables. In 1627, he returned to Prague, and received from the emperor 6000 guilders. He finally became a professor at Rostock, on the recommendation of Albert, duke of Wallenstein, at that time duke of

Mecklenberg, but did not receive the promised compensation. He therefore went to Ratisbon, where he died, in 1630. Kepler was small of stature, thin, and of a weak constitution, and short-sighted. His manners were frequently gay and sportive. He was attached to his science with the deepest love: he sought after truth with eagerness, but forgot, in the search, the maxims of worldly prudence; and there was a certain love of mystery about him, which too often manifested itself in idle astrological visions. He had but a small share of what are commonly esteemed the pleasures of life, but he endured all calamities with firmness. "Kepler," says Lalande, "is as famous in astronomy, for the sagacious application which he made of Tycho's numerous observations (he was not himself an observer), as the Danish astronomer for the collection of such vast materials." The laws of the courses of the planets, deduced by Kepler from those observations, are known in astronomy under the name of the *three laws of Kepler* (*regulae Kepleri*), and on them were founded Newton's subsequent discoveries, as well as the whole modern theory of the planets. The first of these laws is, that the planets do not move, as Copernicus had imagined, in circles, but in ellipses, of which the sun is in one of the foci. For this, Kepler was indebted to the observations which Tycho had made on the planet Mars, whose eccentricity is considerable, and agrees particularly with this rule, in determining which, Kepler went through an indescribably laborious analysis. (See the astronomical works of Lalande, Schubert, and others.) The second law is, that an imaginary straight line from the sun to the planets (the *radius vector*) always describes equal sectors in equal times. By this rule, Kepler calculated his tables, imagining the whole plane of revolution divided into a number of such sectors, and, from this, investigated their respective angles at the sun. This was called *Kepler's problem*. The third law teaches that, in the motion of the planets, the squares of the times of revolution are as the cubes of the mean distances from the sun; one instance of the application of which law, in the want of other means, is in the determination of the distance of the planet Herschel from the sun, it having been ascertained, that its time of revolution amounts to little more than eighty-two years. Kepler's services in the cause of astronomy have placed him high among the most distinguished men of science on record. In Ratisbon, a monument was erected to his memory in 1806, by Charles Theodore von Dalberg. It consists of a Doric temple, in which is placed the bust of Kepler. The most important of his works is his *Astronomia nova, seu Physica Cœlestis tradita Commentariis de Motibus Stellæ Martis* (Prague, 1609, folio)—a work which secures immortality to the author, and is still regarded as classical by astronomers. An account of Kepler's life is prefixed to his *Letters* (printed at Leipsic, in 1718, in folio). We annex the epitaph which he composed for himself:

*Mensus eram cœlos, nunc terra metior umbras;  
Mens cœlestis erat, corporis umbra jactat.*

See the article *Harmony of the Spheres*.

KEPPEL, AUGUSTUS, a British admiral, was the second son of William, earl of Albemarle, entered the sea service at an early age, and accompanied admiral Anson round the world. In 1778, he was appointed to the command of the Channel fleet. July 12, in that year, he fell in with the French fleet, under count D'Orvilliers, off Ushant, when a short but warm engagement ensued. A short delay becoming necessary to repair damages, when that labour was accomplished, the admiral made signal for his van and rear divisions to assume their proper

stations. Sir Hugh Palliser, commanding the rear, took no notice of the signal, and refused to join the commander, until night prevented a renewal of the battle. The conduct of the rear-admiral being severely attacked, and Keppel refusing a disavowal of the charges brought against him, Palliser immediately exhibited articles of accusation against him. Keppel was honourably acquitted, and received the thanks of both houses of parliament for his services. Palliser was next tried, and reprimanded; but the public indignation was so great that he was obliged to resign his seat in the House of commons, and to vacate several offices which he held under government. In 1782, admiral Keppel was raised to a peerage, under the title of *viscount Keppel, baron Eldon*, and was, at two different periods, appointed first lord of the admiralty. He died in October, 1786, unmarried. He was regarded as very able in his profession, and a man of great integrity and humanity.

KERGUELEN TREMAREC, Ives JOURNAL, an eminent French navigator, born at Brest, about 1745. He entered young into the navy, and obtained the rank of lieutenant in 1767. After being employed on an expedition to the coast of Iceland, to protect the whale fishery, he was sent, by his government, on a voyage of discovery, to the south sea. On his return, he gave a flattering account of a supposed continent towards the south pole, some parts of which he had visited. He was sent, in 1773, to make further discoveries; but the result of his researches only served to show the little value of the country he discovered; and he was arrested and confined in the castle of Saumur, after his return to France, on the charge of having ill-treated one of his officers. In his prison, he wrote several memoirs relative to maritime affairs; and, having at length obtained his liberation, he again engaged in the service. He died in 1797. Kerguelen published accounts of his voyage to Iceland, and likewise of his southern expeditions. His name is preserved to the appellation of an island in the southern hemisphere—Kerguelen's Land, or the Isle of Desolation.

KERKE, or KERQUE (the Flemish corruption of the German *Kirke*, the Scottish *Airk*); a church. It occurs in proper names; for instance, *Stevenskerke, Dunkerque*, &c.

KERMES, in zoology. See *Coccus*.

KERMES MINERAL. See *Antimony*.

KERTSCH, or KERCH; a fortress on a peninsula of the same name, in Eastern Taurida, on the bay of Taman, with a safe harbour, important for the commerce of the Black sea and the sea of Anaph, and which Alexander ordered to be opened in 338 B.C. Kertsch and Jenikale, not far distant from it, have a common municipal administration, and contain together 4000 inhabitants, mostly emigrant Greeks. The environs are very fertile, and produce the sugar tree without cultivation. The best wine of the Crimea is also made there. Horses, Angora and Astrachan goats, black and Astrachan sheep, are raised. Considerable quantities of salt are manufactured. This new place enjoys equal privileges with Taganrook and Feodosia. (See *Asfa*.) In the neighbourhood are the ruins of Panticapæum, where Mithridates the Great died, and Nymphaeum. Even to this day, the highest hill near Kerch is called the *Chair of Mithridates*, and the whole peninsula Taman, where the opulent cities of Cimmeria and Phanagoria formerly flourished, contains a treasure of antiquities for future investigators.

KESELSDORF; a village about five miles distant from Dresden, celebrated for the battle fought there Dec. 15, 1745, in which the Prussians, commanded by prince Leopold of Dessau, defeated the Saxons.

(See *Frederic II.*) Near the village are considerable coal mines.

**KETCH**; a vessel equipped with two masts, viz., the main-mast and the misen-mast, and usually from 100 to 250 tons burden. Ketches are principally used as yachts for conveying princes of the blood, ambassadors, or other great personages, from one place to another. Ketches are likewise used as bomb-vessels, and are therefore furnished with all the apparatus necessary for a vigorous bombardment. *Bomb-ketches* are built remarkably strong, as being fitted with a greater number of riders than any other vessel of war; and, indeed, this reinforcement is absolutely necessary to sustain the violent shock produced by the discharge of their mortars, which would otherwise, in a very short time, shatter them to pieces.

**KETCHUP**, or **CATSUP**, Mr Todd defines as "a kind of Indian pickles imitated by pickled mushrooms." Doctor Kitchiner, in his *Apicius redivivus*, devotes ten pages to different varieties of receipts for this sauce. There we may become acquainted with the composition and virtues of numerous catsups, whether they be walnut, mushroom, quintessence of mushroom, quintessence of oysters, cockle, muscle, tomato, white cucumber, or pudding. "Mushroom gravy," says the doctor, "approaches the flavour of meat gravy more than any other vegetable juice, and is the best substitute for it in meagre soups and *extempore gravies*." Again, "What is commonly called *catsup* is generally an injudicious composition of so many different tastes, that the flavour of the mushroom is overpowered by a farrago of garlic, shallot, anchovy, mustard, horseradish, lemon-peel, beer, wine and spices. Ready-made catsup is little better than a decoction of spice, and salt and water, with the grosser part of the mushrooms beaten up into a pulp."

**KEW** is situated on the Thames, about seven miles from London, and one and a half mile from Richmond. Kew palace was improved by Kent, and contains some pictures; but the gardens are the principal object of attraction. They are not very large, nor in their situation advantageous, as it is low, and commands no prospects; but they contain the finest collection of plants in the world, and are decorated with various ornamental buildings, most of which were erected by Sir W. Chambers, about 1760. The first building which appears is the orangery, or green-house, 145 feet long. Near it, in a grove, is the temple of the sun, of the Corinthian order. There is also a physic garden, and, contiguous to it, the flower garden, of which the principal entrance forms one end. The two sides are enclosed with high trees, and the other end is occupied by an aviary of vast depth. From the flower garden, a short winding walk leads to the menagerie, the centre of which is occupied by a large basin of water, stocked with curious water-fowl, and enclosed by a range of cages for exotic birds. The gardens also contain the temple of Bellona, the temple of the god Pan, the temple of Echo, the temple of Solitude, the house of Confucius, a Chinese octagon, painted with historical subjects relating to Confucius, and the Christian missions in China, near which is the engine that supplies the lake and basins in the garden with water, contrived by Mr Smeaton (two horses raise upwards of 36000 hogsheads of water in twelve hours), the temple of victory, the great pagoda, (designed as an imitation of the Chinese Tan.) The base is a regular octagon, forty-nine feet in diameter; and the superstructure is likewise a regular octagon, of ten stories, measuring, from the base to the top of the fleur-de-lis, 163 feet. The walls are composed of very hard bricks; the outside of graystocks, laid with such care, that there is not

the least crack or fracture in the whole structure, notwithstanding its great height. The staircase is in the centre of the building, and from the top is a very extensive view, in some directions upwards of forty miles, over a rich and variegated country. There are also the mosque, besides a Gothic building, representing a cathedral, and the gallery of antiques, the temple of Arethusa, and a bridge from one of Palladio's designs. The ruin, which forms a passage for carriages over one of the principal walks, is built in imitation of a Roman antiquity. These gardens are opened every Sunday, from midsummer to the end of autumn. Population of the parish of Kew in 1831, 837.

**KEY**; an instrument for shutting or opening a lock. The following represents an ancient Roman key, found at Pompeii.

**KEY**, or **KEY NOTE**, in music; a certain fundamental note or tone, to which the whole of a movement has a certain relation or bearing, to which all its modulations are referred and accommodated, and in which it both begins and ends. There are but two species of keys; one of the major, and one of the minor mode, all the keys in which we employ sharps or flats, being deduced from the natural keys of C major and A minor, of which they are mere transpositions.

**KEYS** of an organ; movable projecting levers in the front of an organ, so placed as to conveniently receive the fingers of the performer, and which, by a connected movement with the valves or pallets, admit or exclude the wind from the pipes. See *Organ*.

**Keys**, are also certain sunken rocks lying near the surface of the water, particularly in the West Indies, from the Spanish *cayo* (an islet, rock).

**KEY-STONE** of an arch or vault; that placed at the top or vertex of an arch, to bind the two sweeps together. This, in the Tuscan and Doric orders, is only a plain stone, projecting a little; in the Ionic, it is cut and waved somewhat like consoles; and in the Corinthian and Composite orders, it is a console, enriched with sculpture.

**KEY WEST**; a small island, sometimes called *Thompson's island*, belonging to the United States of America, situated within the reef extending from the Tortugas islands to cape Florida, in lat. 24° 25' N.; sixty miles from cape Sable, the nearest mainland of Florida, and seventy miles from the northern shore of Cuba. It is four and a half miles long, and has an area of about 2000 acres. It has a good soil, which has been yet but little cultivated, and the climate has in general proved extremely healthy. It has, however, in certain seasons, been subject to desolating fevers, which have been attributed to accidental causes. The first settlement upon it was made about the year 1820, after the cession of Florida to the United States. It has now about 100 buildings, some of which are large and commodious, and 300 inhabitants. It has a good harbour, easy of access, and of sufficient water for vessels of the largest size. It is advantageously situated for commerce, and it is already the seat of a considerable trade with the island of Cuba. The commerce between the Atlantic coast and the islands of Cuba and Jamaica, and the ports on the gulf of Mexico, all passes near the island. It is a military post of the United States, and is frequently visited by the ships of war on the West India station. It is the seat of the territorial court of the southern district of Florida, which has frequent jurisdiction of cases of wreckers. It has a marshal and attorney

of the United States, and a collector of the customs. The name *Key West* is said to be derived from *cayo Aueso* (bone islet), a name given to the island by the Spaniards, on account of its shape.

**KHALIF.** See *Caliph*.

**KHAN**; the Turkish name for caravansary (q. v.). We will only add, to what was said under that article, that the caravansaries in towns are of two kinds, those for travellers and pilgrims, where a lodging is furnished gratis, and those for traders, which are usually handsomer and more convenient, and have doors to the apartments, which are well secured, but a small charge is made for each chamber, usually not more than a half-penny or a penny per day. There is also a *droit* of entry, which is more considerable, and a duty on whatever is sold in the caravansary. These establishments belong either to government, or to private individuals, and each is appropriated to some particular country, or to the dealers in some particular kind of merchandise.

*Khan* is also the name of an officer in Persia, answering to *Governor* in Europe. There are *khans* of countries, provinces, and cities, who have different additions to distinguish them. In the north of Asia, this title expresses the full regal dignity.

**KHOH**; a Persian word for *bald*. It has been suggested that the name *Caucasus* may be from *khoh kasp* (bald mountain), having the summit without vegetation. This metaphor is very frequent in geographical names. *Chaumont*, in France, *Kahlenberg*, in Germany, signify the same.

**KIACHTA**; a town of Siberia, in the government of Irkoutsk (q. v.) on the river Kiachta, which forms the boundary between China and Russia, situated in a barren country, destitute of water and wood. Population 4000, in 450 houses. Kiachta and the Chinese town of Maimatchin, situated opposite, on the other bank of the river, are the medium of the Russian over-land trade with China, as settled by the treaty of 1727. The duty on the trade yields an annual income of 7,000,000 roubles to Russia. The whole amount of import and export is estimated at about 30,000,000 of roubles annually. 3,000,000 pounds of tea are imported. Kiachta is 1532 versets from Peking, and 6512 from St Petersburg. A commercial outfit and return between Kiachta and St Petersburg, requires generally two years. The Chinese government often interrupts the commerce, when it thinks it has any cause of complaint against Russia. China lays a duty of five per cent. on all exports and imports.

**KIANG**; a Chinese word signifying *river*; e. g. *Kiang-yuen* (country of river).

**KIANGKU.** See *Yangtse*.

**KIDDERMINSTER**; a market town of England, on the Staffordshire and Worcestershire canal, which was finished in 1774, and passes within 100 yards of the market-place. Kidderminster has long been noted for its manufactures. That of broadcloth prevailed in the reign of Henry the VIII. But the carpet manufacture is that which has taken the firmest root here, has flourished best, and promoted most essentially the trade, wealth, and population of the town. Population in 1831, 20,865.

**KIDNAPPING** is the forcible and wrongful seizing upon any person, with intent to carry him away out of the country or jurisdiction within which he is seized, or to confine him, or sell him into slavery. This is a heinous offence, and was punished by fine, imprisonment, and pillory, by the common law. The statute of 11 and 12 William III., c. 7, provides a punishment by imprisonment for three months, in case the captain of a merchant vessel shall, while abroad, force any person on shore, and wilfully leave him behind, or one shall refuse to bring home any

whom he may have carried out, when the person shall be able and desirous to return.

**KIDNEY**; one of the abdominal viscera, consisting of two voluminous glands, the office of which is to secrete the urine from the blood. One of these glands lies on the right, and the other on the left, of the vertebral column (or back bone). They are both contained in a fatty, cellular substance (*surt*), and are situated behind the *peritonæum*, and before the diaphragm and the *quadratus lumborum*. They are penetrated with blood-vessels and nerves, are of a reddish colour, and more consistent than the other glands. An external cellular membrane, and an internal fibrous membrane, envelope each kidney, which is divided into the cortical substance and the tubulous substance. The former constitutes the exterior part of the kidney, and extends between the cones formed by the latter. It secretes the *urine*, that is, separates its elements from the blood, and combines them, while the latter pours it into the pelvis, a membranous bag situated at the middle of the kidney, from which it is conveyed by the *ureter*, a membranous tube, into the bladder. From the bladder, the urine is evacuated by the *urethra*, a membranous canal passing through the penis. The kidneys are not mere filters or sieves, as was formerly supposed, and as some modern physiologists have maintained; they are true glands, that is, a vascular nervous apparatus, having a particular action for the production of a peculiar fluid. The kidneys are subject to an inflammation, called *nephritis*, and to a nervous pain, called *nephralgia*. The kidney sometimes contains stones, gravel, or sand in the pelvis, and also in the cortical and tubulous substances (*see calculus*), which occasion the most excruciating pain. Diseases of the kidneys are generally occasioned by excess in eating and drinking, particularly in subjects addicted to venery, or accustomed to violent riding, or much walking. Temperance, vegetable diet, warm bathing, abstaining from equitation, &c., are preventives.

**KIDNEY BEANS.** See *French Beans*.

**KIEL**; a city and fine harbour on a bay of the Baltic, in the Danish duchy of Holstein, until 1773 the chief place of the Gottorp (or Imperial Raster) part of Holstein. It contains 7000 inhabitants, and 800 houses. Lat. 54° 19' 43" N.; lon. 10° 15' 20" E. Its university was established in 1665, by Christian Albert, duke of Holstein; hence its name, *Christiana Albertina*. It has, at present, over 250 students, a library of 100,000 volumes, an observatory, and a museum of natural history. There are, also, a seminary for teachers, and other excellent institutions. The environs of Kiel are picturesque. The inhabitants are engaged in commerce. The peace of Kiel, between Denmark and Sweden, and between Denmark and Great Britain, Jan. 14, 1804, was connected with the treaties of Hamover. Feb. 6, 1814, between Denmark and Russia, and that of Berlin, Aug. 25, 1814, between Denmark and Prussia. Denmark ceded Norway to Sweden, and received in return Swedish Pomerania, with the promise of 600,000 Swedish dollars. Great Britain gave back all the Danish colonies, but retained the fleet and Heligoland. Denmark contracted to send 16,000 men against Napoleon, for which Britain gave £33,333 per month subsidies. Prussia ceded Saxe-Lauenburg to Denmark, and undertook to pay the 600,000 Swedish dollars already promised by Sweden, and 2,000,000 more of Prussian dollars, at certain periods, besides 3,500,000 of Prussian dollars to Sweden; in return for which she received Southern Pomerania with Rugen. See Scholl's *Hist. des États de Poir*, x, 219, seq.; xiv, 215, seq.; and xi, 304, seq.

**KIEN-LONG** emperor of China, distinguished as

his love of literature, was born in 1710, and succeeded his father, Yuntschin, in 1745. He favoured the Christian religion in private, but, in 1753, interdicted its exercise by a formal order; and he had previously even persecuted those who openly professed it. The missionaries were, in consequence, obliged to proceed with great caution, although several of them were in the emperor's service, and treated with great respect as men of science and learning. On the suppression of the Jesuits, in 1774, China was less visited by scientific persons than formerly, which induced Kien-Long to send to Canton, and invite artists and learned men of all the European nations, and particularly astronomers. This sovereign possessed, on his own part, a taste for poetry and natural history. Resolving to immortalize the remembrance of his victories by the graver, he engaged French artists to copy some Chinese paintings, in which they were represented; but Louis XV. had them engraved for him at his own expense. The larger Chinese collection on agriculture contains several poems of this monarch on rural occupations and incidents; and he established a library of 600,000 volumes, containing copies of all the most interesting works in China. Into this collection he admitted three books written by the Jesuits, on the Christian religion. A description of the Chinese empire, which appeared in Busching's Magazine, was also compiled by his order. He died at Peking, in 1786, after a reign of fifty years.

KILDA, ST, or HIRTA, the farthest removed island of the Hebrides, is situated in the Atlantic ocean, lat. 57° 50' N., sixty miles west distant from the island of Harris, and about 140 miles from the nearest point of the mainland of Scotland. It belongs to the parish of South Uist. It is three miles in length, two in breadth, nine and a half in circumference, and surrounded with rocks, dangerous of approach, and lofty precipices, inaccessible on every side, except at the only landing-place in a small bay on the south-east; and even there the passage leading to the interior is so contracted and extremely steep, that a few persons only, by hurling stones from the summits of the rocks on either hand, might successfully repel the most hostile attack. The whole surface is rugged, rising into several high mountains; but the soil, which is naturally unproductive, has been rendered tolerably fertile, and produces early crops of barley, oats, potatoes, and culinary herbs, for the use of the inhabitants, the male proportion of which is chiefly employed in fishing and fowling; the fowlers are remarkably dexterous in their occupation, fastening themselves in couples, one at each end of a cow-hide rope, by which they alternately descend from the loftiest cliffs to the frightful length of thirty fathoms, and at the imminent hazard of destruction, there search among the cavities for wild fowl and eggs, with astonishing success. Among the various kinds of birds thus taken is the solan goose; but that most highly esteemed by the natives is the fulmar, which supplies oil for the lamp, ointment for wounds, down for the bed, and the most nutritious food for the body; the female lays but one egg during the season of incubation, and to plunder her nest is considered an act of the highest degree of criminality. The village, which is situated about a quarter of a mile from the landing-place, on a rivulet, originating in the union of several springs, consists of one wide street, formed by two rows of houses built of freestone, and each comprising one apartment for the family, and another for the cattle. The Gaelic is the only language spoken here, in which the minister explains the English Bible to the inhabitants. Mr Macleod is the sole proprietor of St Kilda, and his steward used annually to collect the rents from the produce of the island; but the property is now

under the supervision of a tacksman. The storms during the equinoxes are extremely violent here. In 1730 the small-pox, brought by one of the natives from Harris, made such dreadful havoc here, that only four adults escaped death. The population at present is little above a hundred. Of late years, steam-boats have visited this secluded spot. For a most interesting account of St Kilda, see Dr Macculloch's *Western Isles*.

KILLIGREW. Three brothers of this name, distinguished by their loyalty, wit, and talents, flourished under the two Charleses. They were the sons of Sir Robert Killigrew.—*William*, the eldest, was born in 1605, at Hanworth, Middlesex, and, after going through the usual course of a university education at St John's college, Oxford, made the tour of Europe. On his return to England, he obtained a place at court, as one of the gentlemen ushers of the privy chamber to Charles I. During the civil wars, he suffered materially, both in purse and person, in consequence of his adherence to the royal cause; in recompense for which he received, after the restoration, the honour of knighthood, and, on the marriage of Charles II. obtained the post of vice-chamberlain. He composed four plays—*Selindra*, the Siege of Urban, Ormasdes, and Pandora (Oxford, folio, 1666), popular in their day. His other writings are, *Midnight and Daily Thoughts*, and the *Artless Midnight Thoughts of a Gentleman at Court* (8vo). He died in 1693.

*Thomas*, the second, was born in 1611, and died before his elder brother, in 1682. He was one of Charles I.'s pages, and accompanied the prince of Wales into exile. During his absence from England, he visited France, Italy, and Spain, and, after the restoration, was appointed by the new king (with whom he was a great favourite), one of his grooms of the bedchamber. A vein of lively pleasantry, combined with a certain oddity, both of person and manner, placed him high in the good graces of Charles, who would frequently allow him free access to his person, when characters of the first dignity in the state were refused it, till Killigrew, at length, became almost the inseparable companion of his monarch's familiar hours. He wrote eleven pieces for the stage, which have been collected and printed in one volume folio (1664); but we look in vain in them for traces of that facetiousness and whim, which, together with the encouragement he received from royalty, procured him the appellation of *king Charles's jester*. He lies buried in Westminster abbey.

*Henry*, the youngest of the three, was one year younger than his brother Thomas, whom he survived about six years. He was educated for the church at Christ-church, Oxford, and acted as chaplain to the cavaliers. In 1642, he graduated as doctor in divinity, and obtained a stall at Westminster. On the re-establishment of monarchy, he obtained the living of Wheathamstead, Herts, and the mastership of the Savoy. He wrote a tragedy when only seventeen years old, called the Conspiracy. In 1652, he published a corrected version of this piece, changing the name to that of Pallantus and Eudora.

The females of this family were also distinguished.

Dame *Catharine Killigrew*, wife of Sir Henry, was celebrated as one of the most accomplished scholars of her day. She was the daughter of Sir Anthony Cooke, born about the year 1530, and, to a familiar acquaintance with the classical, as well as some of the Oriental languages, united considerable poetic talent. Her death took place in 1600.

*Anne Killigrew*, daughter of the divine already mentioned, was born in 1660. She gave strong indications of genius at an early age, and became equally eminent in poetry and painting, as well as

distinguished for her piety and unblemished virtue amidst the seductions of a licentious court. She fell a victim to the small-pox, in the summer of 1685, and has been characterised by Wood as "a grace for beauty, and a muse for wit," and celebrated by the greatest of her literary contemporaries, John Dryden.

KILMARNOCK, a thriving town in Ayrshire, situated twelve miles distant from Ayr, and twenty-one and a half from Glasgow. Although a town of some antiquity, it is only of recent years that it has become a place of consideration. Thirty or forty years ago, it was a small irregularly built town; but an act of parliament having passed in 1802 for the general improvement of the place, followed by two others in 1810, for paving, lighting, and watching the streets, and for erecting various public buildings, it now presents a handsome appearance, having an elegant town-house, a bank, printing-offices, a bride-well, a workhouse, a commodious grammar-school, a coffee-room, and other establishments of public utility, besides several places of worship, public schools, and charitable institutions. Kilmarnock obtained its first charter by means of lord Boyd, in 1591, and a renewal of it in 1672, to the earl of Kilmarnock, upon the attainer of whose descendant in 1745, the superiority became vested in the crown. The five deacons of the incorporated trades of the town, in 1700, obtained from the then earl a grant of the whole common good and customs of the burgh. Kilmarnock is the chief manufacturing town in the shire, both for home consumption and exportation. Woollen cloths, carpets, blankets, serges, tartans, stockings, gloves, bonnets, caps, muslins, leather, saddlery, shoes, and a variety of other useful articles are manufactured here; and there are within the town and suburbs mills for spinning wool, tanneries, extensive breweries, an ironfoundry, and a large printfield. In the neighbourhood are several thriving nurseries, the soil and climate being peculiarly adapted to the growth of young trees and shrubs; and about half a mile north-west of the town, is an extensive colliery, whence a railway has been formed to the harbour of Troon, by which the produce is conveyed thither to be shipped. Coal is found in other parts of the parish, which contains 5900 Scottish acres, in general fertile and well cultivated; though towards the north the surface inclines to moss. Kilmarnock, with Port-Glasgow, Renfrew, and Rutherglen, returns one member to parliament. Population of town and parish in 1831, 18,093.

KING (Old Frankish, *chünig*, *chünig*, *kuning*; Anglo-Saxon, *cyning*, *cyng*, *cyng*; German, *könig*; Danish, *konge*; Swedish, *konung*; Finlandish, *kuningas*) is a word of uncertain derivation. The title of *majesty* belongs exclusively to kings and emperors; other privileges, likewise, principally of a ceremonial kind, are connected with the regal title, included in diplomacy under the name of *royal honours* (*honneurs royaux*, *honores regii*). These honours, however, are sometimes enjoyed by states, where the princes do not bear the royal title; thus the late republics of Venice and of the United Netherlands (and now that of Switzerland), the electors (as the elector of Hesse), the grand dukes, possessed them, at least in part. Previously to the French revolution, the following countries gave their princes the regal title: Germany, France, Spain, Portugal, Naples, and Sicily (or the Two Sicilies), Sardinia, Prussia, Bohemia, Hungary, Galicia, and Lodomeria, Poland, England, Ireland, Scotland, Sweden, Denmark, and Norway. After the French revolution broke out, France was struck out from the list of kingdoms, and soon after, Poland; and, on the other hand, while Napoleon stood at the head of France, new kingdoms arose, though some of them enjoyed only an ephemeral existence. Thus

the kingdom of Hettruria was formed from the ancient grand duchy of Tuscany, and a new kingdom of Naples sprang into being, while the old family in the Sicilies still retained the royal dignity (not acknowledged, indeed, by Napoleon). Thus there was a kingdom of Italy, a kingdom of Holland, and, at the beginning of 1806, the kingdoms of Bavaria and Wurtemberg, which were followed, in 1807, by the kingdoms of Saxony and Westphalia. The son of Napoleon was called *king of Rome*, in imitation of the custom which prevailed in the German empire, where the person elected, during the life of the emperor, to succeed at his death, was styled *king of the Romans*. The existence of Hettruria and Holland as kingdoms, however, was soon terminated by France itself; and of Westphalia by the enfranchisement of Germany from the dominion of the French. After the fall of Napoleon, the kingdoms of the Netherlands and of Hanover were established. In place of the kingdom of Italy, arose the Lombardo-Venetian kingdom, under the sovereignty of Austria.—In early times, the chief of an independent state was called *king*; at a later period, the pope and emperor, as spiritual and secular heads of Christendom, pretended to have the right to make kings, until Frederic III., elector of Brandenburg and duke of Prussia, declared himself king of Prussia. Like other subjects of common interest in European politics, the general acknowledgment of the royal title, in any particular instance, is dependent, to a considerable degree, on the will of the most powerful governments. The following monarchs have the titles connected below, in addition to those by which they are usually known. The emperor of Austria is *emperor king of Jerusalem*, actual king of Hungary, Bohemia, the Lombardo-Venetian dominions, Dalmatia, Croatia, Slavonia, Galicia, and Lodomeria; the emperor of Russia has the title of king of Moscow, Kazan, Astracan, Poland, Siberia, and the Taurian Chersonesus; the king of Portugal calls himself, also, king of Algarve; the king of Spain, king of Castile, Leon, Arragon, the Two Sicilies, Jerusalem, Navarre, Granada, Toledo, Valencia, Galicia, Majorca, Seville, Sardinia, Cordova, Corsica, Murcia, Jaen, Algarve, Algeiras, Gibraltar, the Canary Islands, the East and West Indies, of the Islands and Terra Firma beyond the sea; the former kings of France called themselves, also, kings of Navarre; at present, like Louis XVI., in the time of the revolution, they have the title king of the French; the king of the Two Sicilies calls himself, also, king of Jerusalem; the king of Great Britain (i. e. England and Scotland) is also king of Ireland, and the Brunswick house are kings of Hanover; the king of Denmark calls himself, also, king of the Goths and Vandals, as does, also, the king of Sweden and Norway. Where we have used the phrase "is king," we mean that the countries from which the title is derived are actually existing, distinct states, under one head, as Bohemia and Hungary, which have nothing in common, except their monarch. The same is the case with Sweden and Norway. Many of the titles are empty, antiquated designations, retained from a childish love of pomp. Down to the union of Britain and Ireland, the kings of Britain bore the title of kings of France. For information respecting the prerogatives and limitations of the kings of Great Britain, see *Britain*, division *British Constitution*.

KING, WILLIAM; a learned Irish prelate, who was a native of Antrim, but of Scottish extraction. His zealous opposition to the measures of the Roman Catholic party, in the reign of James II., earned him preferment after the expulsion of that prince. After holding several inferior offices, he was made,

in 1702, archbishop of Dublin. He died May 8, 1789, aged seventy-nine. He was distinguished for his wit as well as his learning. Having been disappointed in his expectations of being raised to the primacy of Ireland on the death of archbishop Lindsay, it being assigned as a reason for passing him over, that he was too far advanced in years, he received doctor Boulter, the new primate, at his first visit, without paying him the customary compliment of rising to salute him, apologising for the apparent incivility by saying, "My lord, I am sure your grace will forgive me, because you know *I am too old to rise.*" Archbishop King is principally known at present as the author of a treatise *De Origine Mali*, the object of which is to show that the presence of natural and moral evil in the world is not inconsistent with the power and goodness of the Supreme Being. This work provoked the animadversions of the celebrated Bayle, as it impugned his arguments on the Manichean system. Some remarks on it were likewise published by Leibnitz, whose objections, as well as those of other opponents, are considered in the additions to an English translation of the work, by Law, afterwards bishop of Carlisle.

KING, RUFUS, a distinguished American orator, statesman, and diplomatist, was born in 1755, at Scarborough, in the district of Maine, where his father was an opulent merchant. He was entered at Harvard college, Cambridge, in 1773; but, in 1775, his collegiate pursuits were interrupted by the commencement of the revolutionary war, the buildings appertaining to the institution having become the barracks of the American troops. The students were, in consequence, dispersed until the autumn of the same year, when they re-assembled at Concord, where they remained until the evacuation of Boston by the British forces in 1776. In 1777, he received his degree, and immediately afterwards entered, as a student of law, into the office of the celebrated Theophilus Parsons, at Newburyport. Before he was admitted to the bar in 1778, he volunteered his services in the enterprise conducted by general Sullivan and count d'Estaing against the British in Rhode Island, and acted in the capacity of aid-de-camp to the former. In 1780, he began the practice of his profession, and soon after was elected representative of the town of Newburyport, in the legislature or General Court, as it is called, of Massachusetts, where his success paved the way to a seat in the old congress in 1784. His most celebrated effort in the legislature was made in that year, on the occasion of the recommendation by congress to the several states to grant to the general government a five per cent. impost, a compliance with which he advocated with great power and zeal. He was re-elected a member of congress in 1785 and 1786. In the latter year, he was sent by congress, with Mr Monroe, to the legislature of Pennsylvania, to remonstrate against one of its proceedings. A day was appointed for them to address the legislature, on which Mr King rose first to speak; but, before he could open his lips, he lost the command of his faculties, and, in his confusion, barely retained presence of mind enough to request Mr Monroe to take his place. Meanwhile, he recovered his self-possession, and on rising again, after complimenting his audience by attributing his misfortune to the effect produced upon him by so august an assemblage, proceeded to deliver an elegant and masterly speech. In 1787, when the general convention met at Philadelphia for the purpose of forming a constitution for the country, Mr King was sent to it by the legislature of Massachusetts, and, when the convention of that state was called, in order to discuss the system of government proposed,

was likewise chosen a member of it by the inhabitants of Newburyport. In both assemblies, he was in favour of the present constitution. In 1788, he removed to New York city. In 1789, he was elected a member of the New York legislature, and, during its extra session, in the summer of that year, general Schuyler and himself were chosen the first senators from the state, under the constitution of the United States. In 1794, the British treaty was made public, and, a public meeting of the citizens of New York having been called respecting it, Mr King and general Hamilton attended to explain and defend it; but the people were in such a ferment, that they were not allowed to speak. They therefore retired, and immediately commenced the publication of a series of essays upon the subject, under the signature of Camillus, the first ten of which, relating to the permanent articles of the treaty, were written by general Hamilton, and the remainder, relative to the commercial and maritime articles, by Mr King. The most celebrated speech made by Mr King, in the senate of the United States, was in this year, concerning a petition which had been presented by some of the citizens of Pennsylvania against the right of Albert Gallatin to take a seat in the senate, to which he had been chosen by that state, on the ground of want of legal qualification, in consequence of not having been a citizen of the United States for the requisite number of years. Mr King spoke in support of the petition, and in answer to a speech of Aaron Burr in favour of Mr Gallatin. Mr Gallatin was excluded. In the spring of 1796, Mr King was appointed, by president Washington, minister plenipotentiary to the court of St James's, having previously declined the offer of the department of state. The functions of that post he continued to discharge until 1803, when he returned home. In 1813, he was a third time sent to the senate by the legislature of New York, at a period when the nation was involved in hostilities with Great Britain. His speech on the burning of Washington by the enemy, was one of his most eloquent displays, and teemed with sentiments which had echoes from all parties. In 1816, whilst engaged with his senatorial duties at Washington, he was proposed as candidate for the chief magistracy of the state of New York, by a convention of delegates from several of its counties. The nomination was made without his knowledge, and it was with great reluctance that he acceded to it, at the earnest solicitation of his friends. He was not, however, elected. In 1820, he was re-elected to the senate of the United States, where he continued until the expiration of the term, in March, 1825. Several of the laws which he proposed and carried, in that interval, were of great consequence. On his withdrawal from the senate, he accepted from president Adams, the appointment of minister plenipotentiary at the court of London. During the voyage to Britain, his health was sensibly impaired. He remained abroad a twelvemonth, but his illness impeded the performance of his official duties, and proved fatal soon after his return home. He died like a Christian philosopher, April 29, 1827, in the seventy-third year of his age. The name of Mr King is conspicuous in the annals of the American Union, in connexion, not merely with the history of parties, but with that of the formation and establishment of the federal republican system. Politicians of every denomination bore testimony to the value of his public services, and the eminence of his talents and virtues.

KING AT ARMS, in heraldry; an officer formerly of great authority, whose business is to direct the heralds, preside at their chapters, and have the jurisdiction of armoury. The origin of the title is doubtful. There are three kings at arms in England—

Garter, Clarencieux, and Norroy; the first is called *principal king at arms*, the two others *provincial kings*. Clarencieux is said to be derived from Clarence, brother of Henry V., first king at arms for the south of England. Norroy (Norman French, *northern king*) is king at arms for the north of England. There are also Lion king at arms for Scotland, and Ulster king at arms for Ireland.

**KING-CRAB** (*limulus polyphemus*). This well known inhabitant of the northern coasts of the United States is distinguished from its kindred species by having seven spines on the upper part of the thorax, and three on the upper part of the abdomen: the superior surface of the tail is also provided with numerous spines. The female, including the tail, is about two feet in length, the male somewhat less. It should be noticed that the spines on the thorax and abdomen, although very acute and prominent when the animal is young, become more obtuse as it advances in age, so that, when full grown, they are obsolete, their situation being designated by a tubercle somewhat browner than the surrounding shell. They occur in great profusion in Delaware bay, in the inlets of the New Jersey coast, &c. These crustaceous animals never swim, but change their situations by crawling slowly along on the bottom. The feet are completely hidden by the shell. If, when cast on shore by the waves, they should unfortunately be thrown on their back, they cannot recover their proper position. Hogs are very fond of them, and it is said that these animals appear to know of the inability of the king-crab to escape if it be turned on its back, and take advantage of the circumstance by reversing as many as they can before they proceed to satisfy their appetite. When irritated, they elevate their tail, but are incapable of using it as a weapon of defence. They are never eaten by man, though the eggs are said to form an article of food in China. These are deposited by the female in a hole of considerable width, but little depth, which she forms between high and low water mark. The eyes of this animal, according to the observations of Mr André, consist of a great number of very small cones.

**KINGFISHER** (*alcedo*, Lin.). This genus of birds is distinguished by having an elongated, robust, straight, tetragonal, acute bill, with its margins finely crenate-fimbriate; feet robust; wings rather short; body thick and compact; head large and elongated; plumage thick and glossy. They occur in all parts of the world, especially in warm climates, there being but one species in Europe and one in the United States. The kingfisher frequents the banks of rivers, and is almost always found alone, perched on a branch of a tree projecting over the water, where it remains motionless for hours, watching till some fish comes under its station, when it dives perpendicularly downwards into the water, and brings up its prey with its feet, carries it to land, where it beats it to death, and swallows it entire, afterwards casting up the scales, and other indigestible parts, in the form of balls. There is, perhaps, no animal respecting which the imagination of mankind has invented more fables than respecting this bird. The ancients supposed that it built its nest upon the ocean—

*Incubat halcyone pendentibus aqore nidia. Ovid.*

But, as this floating cradle would be likely to be destroyed by storms, they endowed the bird with powers to lull the raging of the waves during the period of incubation: hence those tranquil days near the solstice were termed *halcyon days*; and, that the voyager might want no accomplishment, they attributed to it the charm of song.\* But these were not all the

wonderful attributes of the kingfisher. Whatever branch it perched on became withered; the body, when dried, preserved clothes from the moth; and, still more extraordinary, it preserved, where it was kept, the peace of families and was not only a safeguard against thunder, but also augmented hidden treasures. But it is not to the fanciful genius of the ancients alone, that this bird is indebted for wonderful attributes. According to Gmelin, the feathers of the kingfisher are employed by the Tartars and Ostiaks for many superstitious practices. The former pluck them, cast them into the water, and carefully preserve such as float, pretending that if with one of these feathers they touch a woman, or even her clothes, she must fall in love with them. The Ostiaks preserve the skin about their persons as an amulet against every ill. But it is not these barbarous nations only that entertain extravagant notions in regard to this bird. It is believed by some persons, that if the body of a kingfisher be suspended by a thread, by some magnetic influence, its breast always turns to the north. The species inhabiting the United States (*A. adrym*), is distinguished by being of a bluish slate colour, with a ferruginous band on the breast, and a spot between and behind the eyes, a large collar round the neck, and the vent white: the head has an elevated crest. It inhabits the whole continent, from Hudson's bay on the north to the equator, and perhaps even still farther south, migrating in cold and temperate regions. See Wilson's *American Ornithology*.

**KING'S ADVOCATE.** See *Advocate of the Crown*.

**KING'S BENCH.** See *Courts of Justice, Division Courts of England*.

**KING'S COLLEGE** (London). This new institution received the royal charter August 14, 1829, and was brought forward under the patronage of the government and the church. The course of education in King's college is divided into a higher and a lower department. The latter division consists of a school for the reception of day scholars, and is distinct from the higher, and intended to afford an education preparatory to it. The studies pursued are the classical elements of mathematics, English literature and composition, and some modern languages, if desired. In the former are comprehended religion and metaphysics, classical literature, mathematics, philosophy, logic, political economy, history, English literature and composition, foreign languages, and subjects connected with particular professions. No person, not a member of the established church, can hold any office of government or instruction in the college, except the professorships of Oriental literature and modern languages. The building forms the eastern wing of Somerset house, comprising a chapel, hall, library, lecture rooms, residences for the professors, &c. (See *Universities, and London University*). —King's college is also the name of one of the colleges at the university of Cambridge. See *Cambridge*.

**KING'S THEATRE, or ITALIAN OPERA HOUSE**, is a fashionable place of amusement in the British metropolis. The performances consist of Italian operas and ballets, and the performers are the most celebrated from the Italian and French stages. The interior is very magnificent, and is nearly as large as the celebrated theatre of La Scala, at Milan. The stage, within the walls, is sixty feet long and eighty broad, and the space across from the boxes on each side, forty-six feet. Each box is enclosed by curtains, according to the fashion of the Neapolitan theatres, and is furnished with six chairs. There are five tiers of boxes, all of which are private property, or are let out for the season to persons of rank and

\* Cum sonat halcyones cantu, nidosque natantes immota gestat, sopitis fluctibus, unda.—Sil. Ital.

fashion. The boxes will accommodate about 900 persons, the pit 800, and the gallery 800. The opera usually opens for the season in January, and continues its performance, on Tuesdays and Saturdays, till August.

KINGSTON; a seaport on the south coast of Jamaica, constituted a city in 1802, situated on a bay or inlet of the sea, in which there is safe anchorage. It was founded in 1693, after the destruction of Port Royal by an earthquake in the preceding year. It has been of late greatly extended, and has many handsome houses. It has two churches, one Episcopal, the other Presbyterian. There is, besides, a theatre, a free-school, established in 1729, a poor-house, and a public hospital. Population—whites, 10,000; people of colour, 2,500; free negroes, 2,500; slaves, 17,000; total, 33,000. Ten miles east of Spanish Town. Lon. 76° 33' W.: lat. 18° N.

KINGSTON, ELIZABETH, duchess of, was born in 1720, and was the daughter of colonel Chudleigh, governor of Chelsea college, who, dying while she was young, left her almost unprovided for. She resided with her mother, who, through the interest of Pulteney, afterwards earl of Bath, procured her the post of maid of honour to the princess of Wales, the mother of George III. Her wit and beauty procured her many admirers, and, in spite of the levity of her manners, a serious offer of marriage from the duke of Hamilton. But while that nobleman was on the continent, Mrs Hanmer, the aunt of Miss Chudleigh, with whom she was on a visit, persuaded her niece to marry privately captain Hervey, a naval officer, afterwards earl of Bristol. She soon conceived a violent dislike of her husband, heightened by the discovery that she had been deceived into an opinion that the duke of Hamilton had forgotten her. Her marriage, which took place August 4, 1744, was kept a secret; and her refusal of advantageous proposals of marriage which she subsequently received, offended her mother, and subjected her to reproaches, which induced her to go abroad. She went in company with a major in the army, with whom she proceeded to Berlin, where they parted. She is said to have been well received by the king of Prussia, and also at the court of Dresden; and, on her return to England (as Miss Chudleigh), she resumed her situation as maid of honour. Desirous of breaking off her union with captain Hervey, she adopted the infamous expedient of tearing the leaf out of the parish register, in which her marriage was entered; but, repenting of this step in consequence of her husband's succeeding to the peerage, she contrived to have the leaf replaced. Not long after, the duke of Kingston made her a matrimonial offer, on which she endeavoured to procure a divorce from lord Bristol. He at first opposed her scheme; but at length he assented to it, and she obtained the wished-for separation. March 8, 1769, she was openly married to Evelyn Pierrepont, duke of Kingston, on whose death, in 1773, she found herself left mistress of a splendid fortune under the condition of her not again becoming a wife. But she did not enjoy her riches undisturbed. The heirs of the duke commenced a suit against her for bigamy, as having been divorced by an incompetent tribunal. She was tried before the house of lords, and was found guilty; but, on her pleading the privilege of peerage, the usual punishment of burning in the hand was remitted, and she was discharged on paying the fees of office. Her property had been so secured that it was not affected by this process. The remainder of her life was spent abroad, and she died at her seat near Fontainebleau, in France, August 28, 1788.

KINSBERGEN, JOHN HENRY VAN, a Dutch

admiral, born May 1, 1735, at Doesborg in Guelderland, died 1820, eighty-four years old. From his ninth year, he served in the army, and from the age of fourteen in the navy, in which he made his way with uncommon rapidity, from the rank of a cadet to that of a vice-admiral. With the permission of the Dutch government, he entered the Russian service in 1767, at the commencement of the war against the Turks. Kinsbergen enjoyed the unlimited confidence of Catharine II., of which he proved himself worthy, by his brilliant success in an engagement on the Black sea, when, with five ships of forty guns, and some smaller men of war, he captured the whole Turkish fleet of thirteen ships of the line. In this battle, several celebrated naval movements were first attempted by him, which have since been generally adopted. His memorial to Catharine, On the Free Navigation of the Black Sea, recommended his political talents to the notice of the empress, who loaded him with marks of esteem. Kinsbergen returned to his country in 1776, and was employed to negotiate a treaty with the emperor of Morocco, in which he was successful. On the famous day of the Doggerbank (August 5, 1781), so honourable to the Dutch marine, Kinsbergen commanded, under admiral Zoutman, seven ships of the line, and had the principal merit of the victory over the British admiral Parker. After the peace of Paris of 1783, the empress of Russia and the king of Denmark endeavoured to induce Kinsbergen to enter their respective marines; but he refused every offer. During the war of the French Revolution, he was of great assistance to his country, particularly in the campaigns of 1793 and 1794. After the unsuccessful campaign of 1795, and the change of administration, Kinsbergen remained in retirement, declining the most brilliant offers. Even Schimmelpenninck, his personal friend, could not tempt him from his retreat, where he occupied himself in study, agricultural pursuits, and the education of the lower classes. King Louis Napoleon appointed him first chamberlain, count of Doggerbank, counsellor of state, and gave him the grand cross of the order of the union. But he could not induce him to leave his country-seat in Guelderland, in the neighbourhood of Appeldoorn, nor to accept any of the salaries which were connected with these appointments. After the union of Holland with France, in 1810, Napoleon also endeavoured to gain him over, and appointed him senator. Kinsbergen could not refuse the dignity, but he declined the income connected with it. Master of a large fortune, he applied it to benevolent and useful institutions. Few men have left a name equally deserving esteem. He was a member of many orders, and a member and correspondent of the principal learned societies. As a writer on navigation and tactics, he is an authority. His maps, including those of the Crimea, are excellent.

KIOSK; a summer-house, with a tent-shaped roof, open on all sides, and isolated. It is supported by pillars (commonly placed in a square), round the foot of which is a balustrade. It is built of wood, straw, or similar materials, and is chiefly erected to afford a free prospect in the shade, but it also serves to embellish a rural or garden view. The word *kiosk* is Turkish. This kind of pavilion has been introduced from the Turks and Persians into the English, French, and German gardens.

KIPPIS, ANDREW, a dissenting divine, was born at Nottingham, March 28, 1725; in 1746, became minister of a dissenting congregation at Boston in Lincolnshire, and, in 1753, pastor to a dissenting congregation in Westminster. In 1763, he was appointed classical and philological tutor to the academy supported in London by the funds of William Coward.

In 1767, he received the degree of doctor of divinity from the university of Edinburgh, and, in 1778 and 1779, became a fellow of the society of antiquaries and of the royal society. He died in 1795. Doctor Kippis laid the foundation of the New Annual Register. He devoted his principal attention during the later years of his life, to an improved edition of the *Biographia Britannica*. This work was conducted on a plan so elaborate, that no termination of it on the same scale is likely to be attempted. The labours of doctor Kippis extended only to five folio volumes, forming a small part of the plan.

KIRCHE; a German word for church, which appears in a great number of geographical words.

KIRCHER, ATHANASIUS; a learned German Jesuit, born at Fulda, in 1602. He was professor of mathematics, philosophy, and the Oriental languages, at Wurtzburg, when the arms of the Swedes disturbed his repose, and he repaired to Avignon, where he continued several years. He wished to return to Germany, but the pope called him to Rome, where he at first taught mathematics in the *collegium Romanum*, and afterwards occupied himself in the study of the Egyptian hieroglyphics. Father Kircher was a good Orientalist, as well as an excellent mathematician; but the fanciful nature of some of his studies has caused most of his productions to be considered rather curious than useful. In his attempts to unravel the hieroglyphics, he occasionally fell into some singular absurdities. His industry as a writer was unwearied, the whole of his works occupying no fewer than twenty volumes in folio, eleven in quarto, and three in octavo. Among these are his *Edipus Ægyptiacus* (4 vols., fol., 1652—55), which contains fanciful explanations of a great number of hieroglyphics. In this work, and in his *Prodromus Coptus* (Rome, 1636, 4to), and his *Lingua Ægyptiaca restituta* (Rome, 1644, 4to), he made investigations respecting the Coptic language. He wrote also *Obeliscus Ægyptiacus*; *Phonurgia Nova*; *Ars magna sciendi seu Combinatoria*; *Prælectiones Magnetica* (folio); *Itinerarium extaticum* (4to); *Mundus subterraneus* (2 vols.); *Musurgia universalis* (2 vols., folio); *Turris Babel*; *China illustrata*; *Primitivæ Gnomonica catoptrica* (4to); *Arca Noë*; *Polygraphia* (folio); *Organum Mathematicum*; *Ars magna Lucis et Umbrae* (folio), &c., &c. In his *Musurgia*, he lays claim to the invention of the Æolian harp; and in his *Phonurgia Nova*, to that of the speaking-trumpet. He was afterwards professor of Hebrew and mathematics at Rome, where he died in 1680. His writings embrace the departments of philosophy, mathematics, physics, mechanics, cosmography, natural history, philology, history, and antiquity. They exhibit great learning, but are disfigured by many extravagances.

KIRGHISES, or KIRGUIS, or KIRGESE, or KIR-GUSES, or, as they call themselves, SARA-KAISAKI (Cossacks of the steppes); a widely extended people of Independent Tartary, occupying a great part of the southern frontier of Asiatic Russia. They are generally considered as the descendants of the most ancient Mongols, who formerly dwelt in the neighbourhood of the Chinese wall. When they were first discovered, at the time of the Russian conquest of Siberia, they were dwelling on the upper Yenesei. Since that time, they have been known as a restless and dangerous people. They now inhabit the wastes between the Ural and the Irtsch, called, by the Russians, the *Kirghiz steppes*. These wastes are bounded west by the Caspian sea and the province of Caucasus, north by the governments of Ufa and Tobolsk, and east by that of Kolivan. They have been long divided into the Great, the Middle, and the Little Hordes. The first, on account of their

valour and the inaccessible mountains in which they dwell, long remained independent, until their submission, in 1819, acknowledged the sovereignty of Russia. The Middle and Little Hordes have recognised the dominion of the Russians since 1731, but have always shown themselves faithless, and disposed to pillage; on which account, lines of small fortresses have been erected along the streams on their frontiers. The Little Horde occupy the westernmost position, and wander over the plains south and east of the Ural, and between the Caspian and Aral. The Middle Horde live farther east, on the vast plains north of lake Aral. These two hordes subsist entirely on their flocks, and have no agriculture. The Great Horde live farther to the east and south, beyond the Aral, and on the Sirr: some of them are pastoral, but a considerable proportion cultivate the land, and inhabit fertile, mild, and well watered countries. In the lofty ranges between Cashgar and Siberia, there is a race called *Wild or Mountain Kirghizes*, fierce, and warlike, amounting to about 50,000. There is another detachment south of Cashgar, an agricultural people, and more civilised than the rest. The Little and Middle Hordes are said to consist each of about 30,000 tents or families, each of about ten persons; total, about 600,000. Their constitution is entirely free and independent. The Khan of the Little Horde is indeed appointed by Russia, but he has scarcely any influence. The Russian government, instead of exacting any tribute, pay regular pensions to all the principal chiefs, in consideration that these turbulent warriors shall not exercise upon the Russian empire those predatory habits for which they have always been famous. The Kirghizes profess the Mohammedan religion, practise polygamy, and live in tents of felt. Their articles of trade are cattle, furs, leather, and coverlets of felt.

KIRK. See Kerke.

KIRK-SESSION; a subordinate ecclesiastical court in Scotland. See *Assembly, General*.

KIRWAN, RICHARD, a distinguished modern writer on chemistry, geology, and the kindred sciences. He was a native of the county of Galway, in Ireland, and was educated at the university of Dublin, where he took the degree of LL.D. He devoted himself with great ardour to chemical and mineralogical researches, and became a member of the royal Irish academy, and also a fellow of the royal society. He published in the Philosophical Transactions for 1780, 1782, and 1783, *Experiments and Observations on the Specific Gravities and Attractive Powers of various Saline Substances*; which important subject he farther prosecuted in the Philosophical Transactions for 1785. In 1784 appeared his *Elements of Mineralogy* (2 vols., 8vo), which was translated into German by Crell, and subsequently republished, with additions and improvements. In 1787, he published an *Essay on Phlogiston and the Constitution of Acids*, designed as a defence of the theory of chemistry advanced by doctor Priestley. This very ingenious production was translated into French by the advocate for the anti-phlogistic hypothesis, and published, with animadversions on the rival system, which made a convert of doctor Kirwan, whose rejection of the principles he had so ably supported, had a considerable influence in producing the revolution which took place in chemical science. He produced, besides the foregoing works, an *Estimate of the Temperature of different Latitudes* (1787, 8vo); a treatise on the *Analysis of Mineral Waters* (8vo), and another on *Logic* (2 vols., 8vo), to which may be added various communications to the learned societies to which he belonged. At Dublin, he founded an association for the express purpose of cultivating mineralogy; and, as a geologist, he advocated what

has been called the *Neptunian theory* of the earth, in opposition to that of doctor James Hutton. His death occurred in 1812.

KIRWAN, WALTER BLAKE; an Irish divine, eminent for his popularity as a preacher. He was born at Galway, in 1754, and educated at the English Catholic college of St Omer's, whence he removed to Louvain, where he took priest's orders, and became professor of philosophy. In 1778, he was appointed chaplain to the Neapolitan embassy in London, and attained some fame by his exertions in the pulpit. In 1787, he resolved to conform to the establishment, and preached to his first Protestant congregation in St Peter's church, Dublin. In 1788, he was preferred to the prebendary of Howth, and to the rectory of St Nicholas, Dublin, and finally presented to the deanery of Killala. Wonders are told of his attraction as a preacher, and it was often necessary to keep off the crowds from the churches in which he preached, by guards, and palisadoes. He died, exhausted by his labours, October 27, 1805, leaving a widow with two sons and two daughters, to the first and last of whom was granted a pension of £300 per annum. In 1814, a volume of his sermons was published, which is the only work of his which reached the press.

KISS. The mutual touching of the lips and the mingling of the breath is one of the most natural expressions of affection among men. The child expresses its love by a kiss, and men in all stages of refinement do the same. Inferior creatures express tenderness in a similar manner, as the billing of doves; and many creatures touch objects of love with the mouth or rather tongue. The faithful dog cannot show his affection to his master more clearly than by licking his hand; but man puts the restraints of reason and decorum on the demonstrations of affection, and the kiss has been subjected to various restrictions among different nations; so that, to this day, a kiss given contrary to the will of the person kissed, may, in Germany, be punished as an *injuria* (q. v.), whilst, on the other hand, it has entered largely into various ceremonials, civil and religious. Kissing the forehead of a person, is a sign of condescension and good-will, the parental blessing being sealed with the father's kiss on the forehead of the child among many nations. Kissing the shoulders, is an expression of inferiority; still more so kissing the hand or the foot; and the sign of the greatest humiliation among the Poles, Bohemians, Russians and Asiatics, is to kiss the ground, as a symbol that the place where the foot of the honoured person has trod is dear to them. The word *kissing* is the usual expression, in Hebrew, to signify adoration; and *adoratio* literally means *touching with the mouth*. In the article *Adoration*, mention has been made of the custom of kissing the hand, among the ancients, and of kissing the foot, originally of every bishop, and, at present, of the pope. The stern Romans held it indecent for a husband to kiss his wife in presence even of a daughter. With some nations, as the Germans and French, it is customary for men to kiss each other after a long absence, &c. In the most ancient times, it was customary to impress kisses on one's own hand, and then make the sign of throwing them to the sun, moon, the stars, (*Job xxxi, 26*), and even to Baal. Homer makes Priam kiss the hand of Achilles. Among the Romans, the higher magistrates gave their hands to be kissed by the lower officers, and, under the emperors, the monarch gave his hand to be kissed to the superior officers, whilst the lower officers paid their homage on their knees, touching the gown of their emperor, or their own hand, &c. Kissing the hand of the sovereign, now forms part of the ceremonial of all European courts.

It is considered a particular mark of grace. Officers are allowed this privilege when they set out on important expeditions, or return from them. In Prussia, alone, the king's hand is never, or, at least, very rarely kissed, as a matter of settled ceremonial. In Spain, the *grandees* perform this ceremony on certain court days. In Britain, it is customary for certain officers to kiss the king's hand, at their first audience. When the emperor of Russia dies, his body is laid out in state, and every one who approaches him kisses his hand. Catholics kiss the bishop's hand, or rather the ring which he wears in virtue of his episcopal office. Kissing the hand was formerly very customary on the European continent, and still is so to a certain degree. A gentleman may kiss a lady's hand; and people of the lower class, to express great gratitude, will not unfrequently kiss the hand of a benefactor. In Russia, all persons have a right to kiss each other on Easter day—the day of rejoicing in the Greek Catholic church. When the wives of European monarchs appear, people generally make a motion as if to kiss the gown, and they offer the hand to be kissed. In Britain, on the first presentation of young ladies of high families at court, the queen salutes them on the cheek. In the same way, she salutes a hostess if she pays a visit. Kissing the foot is a common Oriental sign of respect. The later Roman emperors, whose court ceremonial was mixed with so many servile customs, first introduced this practice into the West. The popes have required it as a sign of respect from the secular power since the eighth century. Pope Constantine I. first had his foot kissed by the emperor Justinian II., on his entry into Constantinople, in 710. Valentine I., about 827, required every one to kiss his foot; and, from that time, this mark of reverence appears to have been expected by all popes. When this ceremony takes place, the pope wears a slipper with a cross, which is kissed. In French, this is called *le baisement des pieds*, the word *baisement* is not used in any other relation. In more recent times, Protestants have not been obliged to kiss the pope's foot, but merely to bend the knee slightly. Even Catholic princes sometimes perform only the genuflexion. When the pope is elected, he is placed on the altar, and the cardinals, first of all, perform the adoration. Each approaches the newly elected pope, and kisses his foot, then his knee, and is then embraced by the pope, and saluted on the cheek. The clergyman sometimes kisses the woman immediately after marriage. The *kiss of peace*, in the Catholic church, forms part of a religious rite. St Peter and Paul end their epistles—"Salute one another with a holy kiss." And it was at first customary among the Christians to give each other the kiss of peace—a symbol of concord and unity—particularly at the *agapes*. (q. v.) Many fathers of the church mention it, as St Justin, Tertullian, St Cyril, &c., and in the apostolic constitutions and all old liturgies, mention is made of it. The heathens, on this account, reproached the Christians with licentiousness, as, from misunderstanding, they also accused them of sacrificing human victims, when the sacrifice of Christ was meant. That these kisses may have had an objectionable tendency, we do not deny, as we know ourselves, that, in Berlin, where a certain sect had reintroduced these kisses with the *agapes*, government found it necessary to prohibit them. In the Greek church, the kiss of peace is given before the oblation, and after having dismissed the catechumens. In the Latin church, the kiss of peace is given immediately before the communion. The clergyman who celebrates mass kisses the altar, and embraces the deacon, saying, *Pax tibi, frater, et*

*ecclesia sancta Dei*; the deacon does the same to the sub-deacon, and says *Pax tecum*; the latter salutes the other clergy. Kissing must have been common with the Jews, since Judas used it as a sign to betray the Saviour.

KITCHINER, DOCTOR, was the son of a Middlesex justice, who was for many years a coal merchant in the Strand. He acquired a handsome fortune, which he bequeathed to his son. Doctor Kitchiner was educated at Eton, after which he settled in London as a physician. Early in life, he married; but a separation from his wife soon after took place by mutual consent, and he was left at liberty to employ his ample fortune in experimental cookery. He treated eating and drinking as the only serious business of life; and, having caught the attention of the public by the singularity of his conduct, he proceeded to promulgate, under the title of the *Cook's Oracle*, the laws of the culinary art, professedly founded on his own practice. He was accustomed to assemble his friends at a *conversazione* at his house on Tuesday evenings, and, for the regulation of these meetings, placed a placard over his chimney-piece, containing these words, "At seven come, at eleven go." He was a great stickler for punctuality, and kept a slate in his hall, on which his hours for receiving visitors were indicated. His appearance, his dress, his usages, his person were all quaint. Besides his *Cook's Oracle*, doctor Kitchiner wrote *Practical Observations on Telescopes* (1815, reprinted for the fourth time in 1825, under the title of *Economy of the Eyes*); *Apicius redivivus*, (1817); the *Art of Invigorating and Prolonging Life* (1822); also the *Traveller's Oracle*, published just after his death; &c. In his private character, doctor Kitchiner is represented as having been an amiable man, respected for his integrity, conciliatory manners, and social virtues.

KLAPROTH, MARTIN HENRY, one of the most scientific German philosophers and chemists, was born Dec. 1, 1743, at Wernigerode, and died Jan. 1, 1817, at Berlin. He was an apothecary till the year 1788. In that year, he became chemist to the academy of sciences, and sold his apothecary's establishment. He was the first who discovered, in the stone called *zircon*, and also, afterwards, in the hyacinth, from Ceylon, a peculiar alkaline earth, to which he gave the name of *zircon earth*, and which has since attracted much attention from the French chemists Morveau and Vauquelin. In 1797, he ascertained, by a masterly analysis, the existence of a distinct metal in the substance called *platina*, to which he gave the name *tellurium*. To the same period belongs, also, the discovery of another species of metal, the titanium, which is of frequent occurrence in combination with the oxide of iron and various earths. We are indebted to his analysis of pitch blende for a third new species with which he enriched the class of metals—the uranium. He subjected meteoric stones to a very thorough and careful analysis, and proved the interesting point of their identity of composition. The result of these, and other more important chemical investigations, are exhibited in his *Contributions to the Chemical Knowledge of Mineral Bodies* (Berlin, 1795—1815, tom. vi.) We have also a chemical dictionary published by him in conjunction with D. Wolff, of which five volumes, and four supplementary volumes, have appeared at Berlin, since 1807, which may be regarded as the most complete and respectable chemical work, in alphabetical arrangement, that Germany has produced.

KLEBER, JEAN BAPTISTE, a French general, distinguished not less for his humanity and integrity, than for his courage, activity, and coolness, was one

of the ablest soldiers which the revolution, so fertile in military genius, produced. His father was a common labourer, and young Kleber was himself peacefully occupied as an architect, when the revolutionary troubles led him to the career of arms. He was born at Strasburg, in 1754, and had received some education in the military academy at Munch. through the agency of some German gentlemen, to whom he had rendered a service. From 1776 to 1783, he had served in the Austrian army against the Turks. Having entered a French volunteer corps as a simple grenadier in 1792, his talents soon procured him notice; and, after the capture of Mayence, he was made general of brigade. Although he openly expressed his horror at the atrocious policy of the revolutionary government, his services were too valuable to be lost, and he distinguished himself as a general of division, in the campaigns of 1796 and 1798. In 1797, Kleber, dissatisfied with the directory, retired from the service; but general Bonaparte prevailed upon him to join the expedition to Egypt. Although no favourite of the general in chief, yet, such were the talents that he displayed in the campaign in Syria, and the battle of Abukir, and such was the esteem in which he was held by the army, that Bonaparte left him the command, when he himself returned to France. His situation was difficult; the army was weakened by a series of laborious marches and sanguinary conflicts, and all communication with France was intercepted; yet he maintained himself successfully against the enemy, and introduced order into the government; but, in the midst of new preparations for securing possession of the country, he was assassinated by a Turkish fanatic, June 14, 1800.

KLEIN; a German word for *small*, prefixed to a great many geographical names.

KLEIST VON NOLLENDORF, EMILIA FREDERIC, COENT, one of the most distinguished Prussian generals in the campaign of 1813 and 1814, against Napoleon, was born at Berlin, in 1762, served in the campaign of 1778, and rose by his courage and military talents, so that, in 1803, he was made reporting adjutant-general to the king of Prussia. After the enterprise of Schill (q. v.), he was made commandant of Berlin—a post which required, at that time, much talent and skill. In 1812, Kleist commanded a corps of Prussians, auxiliary to Napoleon's grand army. He distinguished himself in the battle of Bautzen (q. v.), May 20, 1813, and was one of the plianteries who concluded the armistice. When Napoleon forced the allies to retreat from Dresden into Bohemia, after the battle of Dresden (August 26), Kleist followed the general retreat; but Vandamme had entered Bohemia before him, with 40,000 men, and Kleist had only the alternative of surrendering his army, or fighting for life and death. He took the bold resolution of throwing himself down from the mountains into the rear of Vandamme (August 30), and was victorious at the village of Nollendorf. His success saved Bohemia, against which Napoleon had directed his masterly demonstrations. Kleist was afterwards known by the siffix of *Nollendorf*. Feb. 14, 1814, he was victorious at Jomvillers, in France. In the engagement at Claye, March 25, he led a brigade to an assault in person. Kleist died in 1821.

KLEIST, EWALD CHRISTIAN VON, born March 1715, at Zeblin, in Pomerania, studied for some years at the Jesuit college at Kron, in Great Poland, then at the gymnasium at Danzig, and went, in 1731, to Konigsberg to study law. Besides his acquisitions in mathematics, philosophy, literature, and law, he made great proficiency in modern languages. Having tried in vain, several times to obtain a civil appoint-

sent, he entered the army, and became, in 1736, a Danish officer. He studied, with zeal, the military art, and, when Frederic the Great, of Prussia, began his reign, Kleist entered his service. He always disliked the military profession, which, together with an unfortunate attachment, gave to his poems the tone of melancholy which distinguishes them. Few German poems, from an author without previous reputation, have met with such immediate success, as his *Frühling* (Spring), which was first printed in 1749, for his acquaintance only. In 1757, Kleist was made major. In 1759, he lost his leg in the battle of Kunersdorf: he lay, during the whole night, with his wounds exposed, on the field of battle. The next noon, he discovered himself to a Russian officer, who was passing by, and who had him carried to Frankfort. Eleven days after the battle, the fractured bones parted, and tore an artery, and he died August 24. Kleist was an amiable and upright man. He composed several war-songs, and liked to call himself a Prussian grenadier. His admiration of Frederic the Great was deep, as many of his most beautiful compositions prove. Kleist enjoyed the friendship of many of the most talented men of his nation.

KLEPHTES, (Κλεφτης, κλεπτης), properly a *robber*, is the name given to those Greeks who kept themselves free from the Turkish yoke, in the mountains, and carried on a perpetual war against the oppressors of their country, considering every thing belonging to a Turk a lawful prize, often, as may be easily imagined, exercising their profession on Greeks. Such a population is very common in conquered countries, where there are mountains to afford a retreat to the vanquished. At the time of the conquest of Greece, many inhabitants of the plain retreated to the highlands, where they even formed *κλεφθυρια* (klephtes villages), from whence they surprised and annoyed the Turks. By degrees, their independence was acknowledged by the Turks (as, for instance, in the case of the Mainots), and a militia acknowledged by the Turks was formed among them, which, under the pachas and other officers of the Porte, was intrusted with the maintenance of order in different parts of Greece. The members of this were called *αρχερωλη* and *αρχερωλη* (probably from the Latin and Italian word *archa*, as many words of this description have become incorporated in the modern Greek, partly through the conquest of the country by the Romans, partly by the predominance of Italian on the Mediterranean in later periods; or from *αρχα*, which is connected with the ancient Greek *αρχων*). The leaders were called *capitani* (q. v.), and their dignity appears to have been hereditary. These *armatoloi*, also called *pallikaris*, from the ancient *παλλας* or *παλλας*, returned to their profession of klephtes, when their rights were attacked; as, for instance, when Ali Pacha of Janina attacked the Albanians. They retained a proud feeling of independence, and Greece would never have been freed, had it not been for these robbers, who were the first to take part in the struggle against the Porte in 1821, and furnished the few good soldiers in the land-service of Greece, their leaders becoming the best generals in the Greek service, as Niketas, Colocotroni, &c. (See Greece.) Whole tribes are to be counted among the klephtes; as the Suliots and Chinariots, in the ancient Epirus, and the Sphakiots on the island of Crete. Besides these, there were single klephtes in the Morea, &c. (For their mode of attack, see Hobhouse's *Journey through Albania*, 1817.) The songs of the klephtes, composed among themselves, form part of the modern national Greek poetry, of which Fauriel (*Chants populaires de la Grèce moderne*, 2 vols., Paris, 1824 and 1825) has published several. The same work gives, in a *discours préliminaire*,

interesting details respecting the klephtes and *armatoloi*. The klephtes are hospitable towards those who are not tempting objects of plunder, as the writer can testify.

KLINGEMANN, AUGUSTUS; doctor of philosophy and director of the national theatre at Brunswick; born Aug. 31, 1777, at Brunswick. Inspired by the example of Goethe and Schiller, who had raised the theatre of Weimar to a high degree of perfection, he devoted himself entirely to the theatre of his native place. In 1813, this was raised from a private to a national institution. Klingemann received the direction of it, and, under his superintendence, it became one of the first of the German theatres. Of his dramatic productions, *Heinrich der Löwe*, *Luther*, *Moses*, *Faust*, *Deutsche Treue*, are stock pieces. His *Dramatische Werke* were published at Brunswick, 1817—1818, 12 volumes.

KLINGER, FREDERIC MAXIMILIAN VON, was born at Frankfort on the Maine, in 1753. He fell, when young, into an exaggerated style of writing, but even then produced a great sensation. Few works have stirred the passions more than his *Twins* (*Twillinge*). Goethe speaks favourably of his exterior, his disposition, and his manners. What Klinger was, he became through himself. Rousseau was a favourite author of his. After having studied at the gymnasium of Frankfort, he went to the university of Giessen. His first productions were dramatic. In the war of the Bavarian succession, he entered the military service, and was made a lieutenant in the Austrian army. After the peace, he went (1780) to St Petersburg, and was appointed an officer and reader to the grand-admiral, the grand-prince Paul, with whom he afterwards travelled through Poland, Austria, Italy, France, Switzerland, Germany, &c. In 1784, he was appointed an officer of the military school at St Petersburg, and rose, in the reign of Catharine, to the rank of colonel. In 1799, he was made major-general by the emperor Paul, and director of the corps of cadets. He distinguished himself by an independent uprightness, at a time when the vagaries of Paul made such conduct dangerous. When Alexander ascended the throne, he received several other offices, as the direction of the university of Dorpat, the inspection of the body of pages, &c. After having received many orders, and the income of a crown village for life, he was made lieutenant-general in 1811. He had served forty years, when he retired. He died in February, 1831. In the midst of his many occupations, Klinger was ever alive in the field of poetry. His works are quite peculiar. He collected them in 12 volumes (Königsberg, 1809 to 1810.) *Der Weltmann und der Dichter* is considered by many the best of his productions.

KLOOTZ, ANACHARSIS. See *Clootz*.

KLOPSTOCK, FREDERIC GOTTLIEB, one of the most celebrated of the German poets, was born July 2, 1724, at Quedlinburg. His father, a senator of Quedlinburg, and an eccentric man, removed, after his birth, to Friedeburg, near Wettin, on the Saal, where the young Klopstock spent his childhood, and was subsequently placed at the gymnasium of Quedlinburg. At the age of sixteen, he went to the *Schulpforte*, near Naumburg. Here he made himself perfect in the ancient languages, acquired a decided predilection for the classical writers, and formed the resolution of writing a great epic poem, though he was not determined what subject to choose; and the reign of Henry the Fowler at that time attracted him most. In 1745, he studied theology at Jena, and commenced, in solitude, the first canto of his *Messiah*. In Leipsic, where he went the next year, he formed an acquaintance with Cramer, Schlegel, Rabener, Zacharia, and others, who then published

the *Bremischen Beiträge*, in which the three first cantos of the Messiah appeared, in 1748, and excited universal attention. Some revered the author as a sacred poet; others, particularly the old divines, imagined that religion was profaned by his fictions. A country clergyman came to him, and seriously entreated him, "for the sake of God and religion, not to make Abaddon (a fallen angel) blessed." He likewise underwent some severe criticism, on account of the novelty and originality of the form and spirit of his poem. The work made the deepest impression in Switzerland. In the summer of 1750, he went to Zurich, where much exertion was made to induce him to remain. The people there viewed him with a kind of veneration. He travelled for his amusement through several cantons. In Denmark, too, the three first cantos of his Messiah met with a very favourable reception; and Klopstock was invited by the minister Bernstorff to Copenhagen, with a small pension, to finish the poem. He departed in 1751, and travelled through Brunswick and Hamburg, where he became acquainted with a young lady, who was a great admirer of his poems—the talented Meta (properly *Margaretha*) Møller, the daughter of a merchant there. In Copenhagen, he was received with every mark of kindness and esteem. There he passed the winter, and was introduced, the next summer, by his friend Moltke, to king Frederic V.; and, as the king was to go to Holstein in the summer of 1752, Klopstock took advantage of the opportunity to go to Hamburg, and visit Meta. He spent the whole summer there, and returned again with the king to Denmark. In the summer of 1754, he went back to Hamburg, and was married to Meta. The steps by which his acquaintance with this lady ripened into tenderness, are described with great beauty and simplicity in his well-known letters, written when she had become his wife, to Samuel Richardson, and afterwards published in that writer's correspondence. But he soon lost her. She died in childbed, in 1758. He buried her in the village of Ottensen, near Hamburg, and placed over her remains this simple and beautiful epitaph:

*Saat gesamt von Gott,  
Am Tage der Gerben zu reifen.  
Seed sown by God,  
To ripen for the harvest.*

From 1759 to 1763, he resided alternately at Brunswick, Quedlinburg, and Blankenburg, and afterwards in Copenhagen. In 1764, he wrote his *Hermann's Schlacht* (Battle of Arminius), and sent it to the emperor Joseph, but not with the success which, in his patriotic enthusiasm, he had promised himself. After this, he entered upon his investigations of the German language. In 1771, after Bernstorff had received his discharge, he left Copenhagen for Hamburg, under the character of Danish secretary of legation and counsellor of the margraviate of Baden. In Hamburg, he finished his Messiah. In 1792, he married a second time. His principal amusement in winter was skating; and he was once in imminent danger of losing his life by it. Klopstock died with calmness and resignation, without pain or a groan, March 14, 1803. His body was buried with great pomp and solemnity, in the presence of thousands. Purity and noble feeling were the characteristics of his mind. He was gay and animated; but his sportiveness was always tempered with a sort of dignity, and his satires were ever gentle. His disposition restrained him from intimacy with men of rank; for he hated the chilling condescensions of the great more than an open insult. He loved to retire into the country, with the families of his friends, and was always pleased to be among

children. In the private welfare and happiness of his friends, he took the deepest interest; but dearest of all to him was the memory of his pious brethren, with whom he had been associated in Leipsic, and whom he saw, one after another, dropping into the grave. (See Henry Doering's *Life of Klopstock*, Weimar, 1825.) As a lyrical writer Klopstock is, perhaps, among the most successful of any age. He may well be called the *Poet of modern poetry*; but he is superior to him in richness and deep feeling, as the spiritual world which he paints excels, in intrinsic magnificence, the subjects celebrated by the Grecian poet. His religious edification, as the Festival of Spring, exhibit the creation of the Psalmist. The elegiac odes to *Fanny and Elise* are known to every refined reader, for the melancholy and elevated tone which reigns throughout them. In expressing joyful feelings, as in the ode to the lake of Zurich, and when his strains are almost Anacreontic, as in many small pieces to *Cath*, he never oversteps the limits of Platonic love. His patriotism is strong and ardent, and his letter edification, called forth by the French revolution, in which, at first, he took the warmest interest, and those to which he speaks of the German language and poetry, are distinguished by bold and original turns of expression. Owing to these, and to his frequent allusions to the northern mythology, he is often obscure to many readers; but the most attentive cannot fail clearly to understand and gratefully to venerate Klopstock as a writer of sacred poetry. He gained, however, the brightest and purest fame by his epopee; the first cantos of which, by their prophetic grandeur and the magnificence of their description, their genuine patriarchal tone, and unfeigned sincerity of love and devotion, announced him a rival of Milton. His *Bardade* are dramatized epics, and lyrical scenes for the theatre, rather than tragedies. The choruses possess the highest lyrical beauty, and breathe the most ardent patriotism and independence of feeling. He has idealized the German character as no other one has ever done. Klopstock created for the Germans a simple, strong, free, and genuine poetic language, and essentially influenced the form, by introducing the ancient classic measures, and especially the hexameter; but he was unduly prejudiced against rhyme. He acquired much reputation by his grammatical works. His fragments on Language and the Art of Poetry, his Republic of Letters, and his Conversations on Grammar, explain many difficulties in German grammar and German poetry, although his innovations in orthography, and, on the whole, several peculiarities of his style, cannot meet with general approbation. Klopstock's works were published at Leipsic, 1798—1817, twelve volumes, &c. They have lately appeared in a pocket edition. The 100th anniversary of his birth was celebrated at Quedlinburg and Altona, July 2, 1824, and a monument has been erected to him in Quedlinburg.

KLOTZ, CHRISTIAN ANTONIUS, was born September 23, 1738, at Bischofswerda, in Lusatia. He studied at Jena, and, in 1762, was appointed professor of philosophy in Göttingen. His patron, Johann Julius, recommended him to Frederic the Great, and he went, in 1765, to Halle. The king esteemed him as an eminent scholar. Klotz distinguished himself chiefly by his Latin poems, his systematic treatise, his works on the study of antiquity, and on the value and mode of using ancient gems. After having contributed much to the *Deutscher Bibliothek*, under the signature E. he established a paper in opposition to it, called *Acta Literaria*. Lessing was the antagonist and wittiest of his opponents. His dispute with Lessing and Burmann took a tone of underhand

Klotz was of an ardent temperament. Thorough in Greek and Latin, of modern languages he knew little. An irregular life hastened his death. He died December 31, 1771.

KNEE; a crooked piece of timber, having two branches or arms, and generally used to connect the beams of a ship with her sides or timbers. The branches of the knees form an angle of greater or smaller extent, according to the mutual situation of the pieces which they are designed to unite. One branch is securely bolted to one of the deck beams, and the other in the same manner strongly attached to a corresponding timber in the ship's side. By connecting the beams and timber into one compact frame, they contribute greatly to the strength and solidity of the ship, and enable her to resist the effects of a turbulent sea. In fixing these pieces, it is occasionally necessary to give an oblique direction to the vertical or side branch, in order to avoid the range of an adjacent gun-port, or because the knee may be so shaped as to require this disposition, it being sometimes difficult to procure so great a variety of knees as may be necessary in the construction of a number of ships of war. The scarcity of these pieces frequently obliges shipwrights to form their knees of iron.

KNEES, in Russia; noblemen of the first class, who, however, have no more authority over their vassals than other landholders. A number of these nobles are descended from the former ruling families of particular provinces of the Russian empire. Of such families, there are eighteen, as the Dolgorucky, Repnin, Scherbatow, Wazneskoy, Labanow, who are all descended from the family of Rurik. The czar allows them to retain the arms of the provinces which their forefathers ruled. Individuals of these families have been illustrious in the civil and military service of their country. There are also some nobles of this class sprung from collateral branches of the family of Jugellons, which formerly ruled in Lithuania or Poland, and is extinct in its principal line. There are others, who claim a descent from independent Tartar khans. The last class of Knees consists of the descendants of noble members of Tartar tribes, who, after the subjugation of the tribes, embraced the Christian religion, and received the above title from the Russian sovereigns.

KNELLER, SIR GODFREY, an eminent portrait painter, born at Lubek, about 1648, was designed for a military life, and sent to Leyden to study mathematics and fortification, but, showing a decided bent for painting, was placed under Bol and Rembrandt at Amsterdam. He visited Italy in 1672, where he became a disciple of Carlo Maratti and Bernini, and painted several historical pieces and portraits both at Rome and Venice. On his return, he was induced to visit England, in 1674; and, having painted a much admired family picture, which was seen by the duke of York, the latter introduced the painter to Charles II., by whom he was much patronised. He was equally favoured by James II. and William III., for the latter of whom he painted the beauties at Hampton court, and several of the portraits in the gallery of admirals. He also took the portrait of the czar Peter for the same sovereign, who, in 1692, knighted him, and made him gentleman of the privy chamber. Queen Anne continued him in the same office, and George I. made him a baronet. He continued to practise his art to an advanced age, and had reached his twenty-fifth year at his death, in 1723. His interment took place in Westminster abbey, under a splendid monument erected by Rysbrach, on which appears an epitaph by Pope. The airs of his heads are graceful, and his colouring is lively, true, and

harmonious; his drawing correct, and his disposition judicious. He displays a singular want of imagination in his pictures, the attitudes, action, and drapery being insipid, unvarying, and ungraceful. See Walpole's *Anecdotes of Painting*.

KNIEPHAUSEN, a lordship on the Jade, in the duchy of Holstein-Oldenburg, containing about thirty-two square miles, and 2900 inhabitants, has belonged, since 1757, to the counts of Bentink; was formerly a sovereign state, but was attached, in 1807, to the department of East Friesland, in Holland; in 1810, to the department of Eastern Ems, in France; and was sequestered, in 1813, on account of the lord having taken part with the allies. Subsequently, it was occupied by Oldenburg, which deprived the lord of his sovereignty, but left him in possession of the revenue, &c. In this condition he has been obliged to remain, as the German diet would not recognise him as an independent prince. The name *Kniephausen* is derived from a castle, to which belong eight houses with fifty inhabitants, and in which the chancery, archives, &c., of this Lilliputian government are kept. At the congress of Aix-la-Chapelle, the lord of Kniephausen appeared, and gave rise to much ridicule, by assuming the airs of an independent prince.

KNIGGE, ADOLPHUS FRANCIS FREDERIC LOUIS, Baron de, was born October 16, 1752, at Brendenbeck, not far from Hanover. His father died in 1766, leaving him an estate deeply embarrassed. In 1769, he went to the university of Gottingen. In 1777, he was made a chamberlain at Weimar. He died at Bremen, May 6, 1796, after a rather unsettled life. Knigge wrote a variety of works. His novels were once very popular, on account of their easy style of narration, and a tinge of satire and popular philosophy. His *Journey to Brunswick* was, for a considerable time, much read. The work which gave him the greatest reputation was his *Ueber den Umgang mit Menschen* (On Intercourse with Men) a book which contains some good advice, but is disfigured by a minuteness of petty precepts. Knigge was also a member of the Illuminati, and thus became implicated in some of the disputes relating to that order. See *Short's Biography of the Baron Adolphus von Knigge*, Hanover, 1825.

KNIGHT, in chess. The move of this piece has given rise to an interesting problem, in regard to the various modes by which the chess-board may be covered by the knight. The path of the knight over the board is of two kinds, terminable and interminable. It is interminable whenever the concluding move of a series is made in a square, which lies within reach by the knight of that from which he originally set out, and is terminable in every other instance. Euler, in the *Memoirs of the Academy of Berlin*, for 1759, has given a method of filling up all the squares setting out from one of the corners. He has likewise given an interminable route, and has explained the method by which the routes may be varied, so as to end upon any square. Solutions of the same problem have also been given by Montmort, Demolivre, and Mairan.

KNIGHT, RICHARD PAYNE; a patron of learning and the fine arts, to the study and encouragement of which he devoted a great portion of his time and ample fortune. His father, from a dread lest his son's constitution should be impaired by the discipline of a public school, kept him at home till his fourteenth year; but, on his decease, young Knight was placed at a large seminary, where he soon distinguished himself by his progress in classical literature, his favourite study. His splendid collection of ancient bronzes, medals, pictures, and drawings, in his museum at his house in Soho square, gave equal proofs of his

taste and liberality. This collection he bequeathed, at his death, to the British museum. His principal writings are, *Remains of the Worship of Priapus*, lately existing in Naples, and its Connexion with the Mystic Theology of the Ancients (4to, 1786); an *Analytical Essay on the Greek Alphabet* (4to, 1791); *Analytical Inquiry into the Principles of Taste* (8vo, 1805); and *Prolegomena in Homerum*, reprinted in the *Classical Journal*. He was also author of some poems. He died in 1824, aged 76.

KNIGHTHOOD. See *Chivalry*.

KNIGHTS OF ST JOHN. See *John, Knights of St.*

KNIGHTS OF THE SHIRE, or KNIGHTS OF PARLIAMENT, in the British polity, are two knights, or gentlemen of estate, who are elected on the king's writ, by the freeholders of every county, to represent them in parliament. The qualification of the knight of the shire is, to be possessed of £600 per annum in a freehold estate.

KNIGHTS TEMPLARS. See *Templars*.

KNIPIAUSEN. See *Kniephausen*.

KNIVES. See *Cutlery*.

KNOLLES, RICHARD, author of a *History of the Turks*, was entered at the university of Oxford about 1560, and became a fellow of Lincoln college, which he left to be master of the free school of Sandwich, in Kent. He composed his *History of the Turks* (folio, 1610), being the labour of twelve years. It has passed through several editions, and is executed in a manner which has transmitted his name with honour to posterity. Several continuations have appeared, the last of which is that of Sir Paul Rycaut. Knolles is also author of the *lives and conquests of the Ottoman kings and emperors until 1610*, and a *Brief Discourse on the Greatness of the Turkish Empire*. He translated Bodin's *Six Books of a Commonwealth*.

KNOUT; the severest punishment in Russia. The criminal, standing erect, and bound to two stakes, receives the lashes, which are inflicted with a leather strap, in the point of which wire is interwoven, on the bare back. Almost every lash is followed by a stream of blood. From 100 to 120 lashes are the highest number inflicted, and are considered equal to the punishment of death. If the criminal survives, he is exiled for life into Siberia. Formerly, the nose was slit up, and the ears cut off, in addition, and a W (wound, rogue) cut in the skin of the forehead, and made indelible by rubbing in gunpowder. At present, the two former punishments, at least, are abolished. If the criminal is sentenced to a smaller number of lashes, the last part of the punishment is not inflicted, and he is sent to Siberia for a few years only.

KNOX, JOHN, the chief promoter of the reformation in Scotland, was descended from an ancient family, and born at Gifford, in East Lothian, in 1505. He received his education at the university of St Andrews, where he took the degree of master of arts much before the usual age. Having embraced the ecclesiastical profession, he began, as usual, with the study of scholastic divinity, in which he so much distinguished himself, that he was admitted into priest's orders before the time appointed by the canons. He soon became weary of the theology of the schools, and resolved to apply himself to that which was more plain and practical. This alteration of opinion led him to attend the sermons of Thomas Guillaume, or Williams, a friar of eminence, who was so bold as to preach against the pope's authority; and he was still more impressed by the instructions of the celebrated George Wishart, so that he relinquished all thoughts of officiating in the church of Rome, and became tutor to the sons of the lairds of Long Niddrie and Ormiston, who had embraced the reformed doctrines. Here he preached not only to his pupils, but to the

people of the neighbourhood, until interrupted by cardinal Beaton, archbishop of St Andrews, who obliged him to conceal himself; and he thought of retiring to Germany. The persuasion of the fathers of his pupils, and the assassination of Beaton by the Leslies, encouraged him to remain. He took shelter, under the protection of the latter, in the castle of St Andrews, where, notwithstanding the opposition of the clergy of St Andrews, he preached the principles of the reformation with extraordinary boldness, until the castle of St Andrews surrendered to the French in July, 1547, when he was carried with the garrison into France, and remained a prisoner on board the galleys until the latter end of 1549. Being there set at liberty, he passed over to England, and, arriving in London, was licensed either by Cranmer or the protector Somerset, and appointed preacher, first at Berwick, and afterwards at Newcastle. In 1552, he was appointed chaplain to Edward VI., and preached before the king, at Westminster, who recommended Cranmer to give him the living of All-hallows, in London, which Knox declined, not choosing to conform to the English liturgy. It is said that he refused a bishopric, regarding all prelacy as an avouring of the kingdom of antichrist. He, however, continued his practice as an itinerary preacher, until the accession of Mary, in 1554, when he quitted England, and sought refuge at Geneva, where he had not long resided before he was invited, by the English congregation of refugees at Frankfort, to become their minister. He unwillingly accepted this avocation, at the request of John Calvin, and continued his services until embroiled in a dispute with doctor Cox, afterwards bishop of Ely, who strenuously contended for the liturgy of king Edward. Knox, in his usual style of bold vituperation, having in a treatise published in England, called the emperor of Germany as great an enemy to Christ as Nero, his opponents accused him to the senate of treason, both against the emperor and queen Mary; on which he received private notice of his danger, and again retired to Geneva, whence, after a residence of a few months, he ventured, in 1555, to pay a visit to his native country. Finding the professors of the Protestant religion greatly increased in number, and formed into a society under the inspection of regular teachers, he finally joined them, and produced so great an effect by his exertions, both in Edinburgh and other places, that the Roman Catholic clergy, alarmed at his progress, summoned him to appear before them in the church of the Blackfriars, in that metropolis, May 15, 1556. This summons he purposed to obey, relying on the support of a formidable party of nobles and gentry, which so alarmed his opponents, that they dropped the prosecution. Thus encouraged, he continued preaching with additional energy and boldness, and was even induced to write to the queen regent, Mary of Lorraine, a letter, in which he earnestly exhorted her to listen to the Protestant doctrines. While thus occupied, he was strongly urged to pay a visit to the English congregation at Geneva; and he accordingly departed for that place in July, 1556. He was no sooner gone than the bishops summoned him to appear before them; and, as that was impossible, they passed sentence of death against him as a heretic, and burned him in effigy at the cross at Edinburgh. Against this sentence he drew up an energetic appeal, which was printed at Geneva, in 1558, previously to which, he was invited to return to Scotland, and had actually reached Dieppe on his way, when he received other letters recommending delay; which epistles he answered by such strong remonstrances against timidity and backsliding, that those to whom he addressed them entered into a solemn bond or covenant, dated December 3.

1557, "that they would follow forth their purpose, and commit themselves, and whatever God had given them, into his hands, rather than suffer idolatry to reign, and the subjects to be defrauded of the only food of their souls." Knox, in the mean time, had returned to Geneva, where he published his treatise entitled the *First Blast of the Trumpet* against the monstrous Regiment of Women, chiefly aimed at the cruel government of queen Mary of England, and at the attempt of the queen regent of Scotland to rule without a parliament. A Second Blast was to have followed; but the accession of queen Elizabeth to the throne of England, who was expected to be friendly to the Protestant cause, prevented it. In April, 1559, he would have visited England, but was prevented by the resentment felt by Elizabeth at his late treatise. He therefore proceeded directly to Scotland, where he found a persecution of the Protestants just ready to commence at Stirling. He hurried to the scene of action to share the danger, and, mounting a pulpit, inflamed the people by a vehement harangue against idolatry. The indiscretion of a priest, who, immediately on the conclusion of this discourse, was preparing to celebrate mass, precipitated his hearers into a general attack on the churches of the city, in which the altars were overturned, the pictures destroyed, the images broken, and the monasteries almost levelled to the ground. These proceedings were censured by the reformed preachers, and by the leaders of the party. From this time, Knox continued to promote the reformation by every means in his power, and, by his correspondence with the secretary Cecil, was chiefly instrumental in establishing the negotiation between the congregation and the English, which terminated in the march of an English army into Scotland. Being joined by almost all the chief men of the country, these forces soon obliged the French troops, who had been the principal support of the regent, to quit the kingdom; and the parliament was restored to its former independence. Of that body, the majority had embraced Protestant opinions, and no opportunity was omitted of assailing the ancient religion, until at length the Presbyterian plan recommended by Knox and his brethren, was finally sanctioned, the old ecclesiastical courts being abolished, and the exercise of religious worship, according to the rites of the Roman church, prohibited. In August, 1561, the unfortunate Mary, then widow of Francis II., king of France, arrived in Scotland to reign in her own right. She immediately set up a mass in the royal chapel, which, being much frequented, excited the zeal of Knox, who was equally intolerant with the leaders of the conquered party; and, in the face of an order of the privy council, allowing the private mass, he openly declared from the pulpit, "that one mass was more frightful to him than 10,000 armed enemies, landed in any part of the realm." This freedom gave great offence, and he and the queen had long and angry conferences with him on that and other occasions, in which he never paid the slightest homage either to sex or rank. He reached with equal openness against the marriage of Mary; and Darnley, after his union, being induced to hear him, he observed, in the course of his sermon, "that God set over them, for their offences and iniquity, boys and women." In the year 1567, he preached a sermon at the coronation of James VI., when Mary had been dethroned, and Murray appointed regent. In 1572, he was greatly offended at a convention of ministers at Leith, for permitting the titles of *archbishop* and *bishop* to remain during the king's minority, although he approved of the regulations adopted in reference to their elections. At this time, his constitution was quite broken, and received an additional shock by the news of the

massacre of St Bartholomew. He had, however, strength enough to preach against it, which he desired the French ambassador might be acquainted with, but soon after took to his bed, and died, Nov. 24, 1572. He was interred at Edinburgh, several lords attending, and particularly the earl of Morton, that day chosen regent, who, when he was laid in his grave, exclaimed, "There lies he who never feared the face of man, who hath been often threatened with dag and dagger, but yet hath ended his days in peace and honour; for he had God's providence watching over him in an especial manner when his life was sought." The character of this eminent reformer has been sketched by doctor Robertson, in his *History of Scotland*, who, in observing upon the severity of his deportment, impetuosity of temper, and zealous intolerance, observes, that the qualities which now render him less amiable, fitted him to advance the reformation among a fierce people, and enabled him to encounter dangers, and surmount opposition, to which a more gentle spirit would have yielded. John Knox was a man of exalted principles, great intellectual energy, undaunted intrepidity, and exemplary piety and morality. He was twice married, and had two sons by his first wife. His writings, in addition to those already mentioned, are, a *Faithful Admonition to the Professors of the Gospel of Christ in the Kingdom of England* (1554); a *Letter to Queen Mary, Regent of Scotland*; a *Steady Exhortation to England for the speedy embracing of Christ's Gospel*. After his death appeared his *History of the Reformation of Religion within the Realm of Scotland*, to the fourth edition of which (Edinburgh, 1732, folio) are appended all his other works. See *M'Crie's Life of Knox*.

KNOX, VICKSIUS, D. D.; an eminent divine, author of a variety of works, both in theology and polite literature. He was born Dec. 8, 1752, and educated at Oxford. On the death of his father, he was chosen his successor in the head-mastership of Tunbridge grammar school, over which he presided thirty-three years, till, retiring in 1812, he was himself, in turn, succeeded by his son. His works, many of which have been translated into various European languages, are, *Essays, moral and literary* (three vols. 8vo and 12mo); *Liberal Education* (two volumes, 8vo and 12mo); *Winter Evenings* (three volumes, 8vo and 12mo); *Personal Nobility, or Letters to a young Nobleman* (one volume, 12mo); *Christian Philosophy* (two volumes, 12mo); *Considerations on the Nature and Efficacy of the Lord's Supper* (one volume, 8vo), and a pamphlet on the National Importance of Classical Education, with a variety of sermons on different occasions; expurgated editions of Horace and Juvenal, and a series of selections from the works of the best English authors, generally known as *Elegant Extracts*, and *Elegant Epistles*. Doctor Knox wrote the Latin language with great purity and elegance, both in prose and verse. He died Sept. 6, 1821.

KOBOLD, in Germany; a spirit which differs from the spectre in never having been a living human creature. It corresponds to the English *goblin*. The kobold is connected with a house, or a family, and appears in bodily shape. Though inclined to mischievous teasing, they do, on the whole, more good than evil to men, except when irritated. In the mines, they are thought to appear, sometimes in the shape of a blue flame, sometimes in that of a dwarfish child, and to indicate rich veins. They do the miners mischief when disturbed by them.

KOCH, CHRISTOPHER, WILLIAM, professor of law, at Strasburg, and a writer well versed in the history of the middle ages, born 1737, at Buxweiler, in Alsace, conducted the school for teaching public law in Strasburg with such success, that scholars flocked

thither from the most distant countries. In 1761, Koch published his *Commentatio de Collatione Dignitatum et Beneficiorum ecclesiasticorum in Imperio Germanico*, and, in 1789, his Commentary upon the Pragmatic Sanction. In Paris, he collected (1762) materials for the continuation of the *Historia Zuerin-go-Badensis*, which appeared under the name of Schoepflin, who, however, had only composed the first volume. In 1780, Joseph II. conferred upon Koch the rank of nobleman. He remained a professor in Strasburg, until the university was broken up. In 1789, he was sent as deputy to Paris, by the Protestants in Alsace, in order to obtain the acknowledgment of their civil and religious freedom, which was effected by the decree of the 17th August, 1790. After the breaking out of the revolution, he was sent, by the department of the Lower Rhine, as deputy to the legislative assembly, where he showed himself a friend to constitutional monarchy. The anarchists threw him into prison, from which he was not delivered till after eleven months' confinement, and the overthrow of Robespierre. In 1802, he was appointed a member of the tribunate, in which capacity he did much for the restoration of order in church affairs, and the re-establishment of the Protestant university in Strasburg. After the dissolution of the tribunate, Koch refused to fill any other office; but the government granted him, without any solicitation on his part, a salary of 3000 francs, and, in 1810, the title of rector in the university at Strasburg. He died Oct. 25, 1813. Besides the above-named works, he is the author of the following:—*Tables généalogiques des maisons souveraines de l'Europe* (Strasburg, 1782—1784); *Hist. abrégée des Traités de Paix depuis la Paix de Westphalie* (Basil, 1791, 4 vols.; continued by Scholl, Paris, 1818, 15 volumes); *Tableaux des Révolutions de l'Europe depuis le bouleversement de l'Empire Romain en Occident* (Basil, 1802, Paris, 1814 et seq., four vols.); and *Table des Traités entre la France et les Puissances étrangères depuis la Paix de Westphalie*; with a new collection of diplomatic documents (Basil, 1802). Koch was a man of great acuteness, equanimity, patience, and nobleness of character.

KOENIG; German for *king*; prefixed to many geographical names, as, *Königsberg* (king's mountain).

KOH; an Indo-Germanic word, signifying *mountain*; e. g. *Hindookoh* (mountains of India).

KOLA; a seaport of Russia, the chief town in Russian Lapland (now called the circle of Kola), in Archangelskoe; 540 miles N. Petersburg; lon. 33° 0' E.; lat. 68° 32' N.; houses, fifty; churches, two. It is situated near the North sea, on the river Kola, which forms a bay at its mouth, where is a considerable fishery for whales, sea-dogs, and other fish, which the inhabitants cure for sale. The circle, including the whole of Russian Lapland, is very dreary and thinly peopled, supposed to contain not more than 2000 inhabitants.

KOLBERG. See *Colberg*.

KOLIN. See *Colin*.

KOLLER, BARON OF; Austrian field-marshal lieutenant; one of the commissioners who accompanied Napoleon, in 1814, to Elba, after his abdication. Koller had to protect Napoleon against a rabble infuriated by priests and ultras, and always preserved the great coat of Napoleon, who had put on his (Koller's) uniform, in order to be less exposed to danger. When Koller returned from Elba, he fulfilled Napoleon's wish to conclude a treaty of commerce between Genoa and Elba. The conduct of Koller is highly praiseworthy, if we consider how much the passions of men were excited against Napoleon, and how much a liberal treatment of him was misconstrued. General Koller afterwards served with the Austrian

army in Naples. He died Aug. 23, 1826. He left an excellent collection of antiques.

KOM, or COM, or KOOM (ancient *Chosra*; a town of Persia, in Irak; 150 miles N. Ispahan; lon. 51° 14' E.; lat. 34° 20' N.; population, about 15,000. It is said to have contained, formerly, 15,000 houses, but is now much reduced, and exhibits extensive ruins. It is esteemed by the Persians a holy city, and has a celebrated mosque, and an asylum for debtors, who are protected and supported. One of the mosques is highly esteemed by the Persians, because of the sepulchres of Shah Sophy, and his son Shah Abbas II., and that of Sidy Fatima, grand daughter of Mohammed. These tombs are frequented by pilgrims from all parts of Persia, who resort thither once a year to pay their devotions. Kom is celebrated for manufacturing the best sabres and poniards of all Persia. The walls of the town are lofty, and it has seven gates. The grand bazar crosses the town from one gate to the other; besides which there are others well furnished with coffee-houses, and shops of various kinds. The country round about is fertile in rice and fruit.

KOMORN, the capital of the county of Komorn in Hungary, with 11,500 inhabitants, has a gymnasium, and carries on some commerce. On the island of Schutt, 2000 paces distant, between the War and Danube, is a fortress, recently erected, which is rendered almost impregnable by nature and art.

KONIGSBERG (that is, *king's mountain*); the capital of Prussia Proper, seat of many civil and military authorities, and superior judicial tribunal; 63,800 inhabitants; 4108 houses; lat. 54° 42' 13" N. lon. 20° 29' E. It is situated on the Pregel, not far from the influx of this river into the Frische Haff. Königsberg is an important seaport of the Baltic, and formerly belonged to the Hanseatic league. It has some considerable buildings, as, for instance, the cathedral, with the tombs of the grand masters of the Teutonic order, and the dukes. The university of Königsberg was founded in 1544, by the margrave Albert I., duke of Prussia, and has at present 22 students. It is largely endowed for poor students. The library contains 60,000 volumes. The astronomer Bessel is a professor of this university. Kant taught here a long time. Large vessels cannot sail up to the city, but they are obliged to remain at Pillau, the fortress and port of Königsberg. Its commerce has very much declined.

KONIGSMARK, MARIA ADELAIDE, countess of one of the many mistresses of Augustus II., king of Poland, and elector of Saxony, born about 1674, was descended from one of the oldest families of Brandenburg. She was one of the most celebrated women of her age, on account of her personal charms and uncommon talents, and of the part which she performed in politics. While a girl, she wrote and spoke Swedish, German, French, Italian, and English; read the classics in the original, had an extensive knowledge of history and geography, and even composed poems in French and Italian. She played several instruments, composed music, and sang, as painted with great skill. Several proofs of her talent for painting still remain at Quedlinburg. She had also a delicate wit, and fine powers of conversation. Thus gifted and accomplished, she arrived, in 1694, in Dresden, with her two sisters. The elector fell in love with her at first sight. She rejected him a long time, all his offers, though he tried every means to gain her: at last she yielded, and appeared at court as his mistress. She bore him a son, the famous marshal Saxe (q. v.). But when the passion of the fickle king cooled, the countess knew how to sustain her misfortune with dignity; and he afterwards remained on terms of friendship with her. But

influence she was appointed, by the court of Vienna, superintendent of Quedlinburg (in 1700), where she resided, at intervals, until her death. The king's esteem for her talents appears from the circumstance that he sent her, in 1702, to Charles XII., to negotiate a peace; but Charles refused to see her. She died in 1728. She was beloved by all around her, and very benevolent towards the poor. Her brother, count Philip Christopher, the last male of this family, was assassinated, in 1694, in the castle of Hanover, by the order of the elector Ernest Augustus, because he had offered to assist the princess Sophia Dorothea (who died in prison at Ahlen, 1726) in her projected flight.

**KONIGSTEIN**; a mountain-fortress, on the Elbe, in the kingdom of Saxony, not far from the frontier of Bohemia. It is impregnable. A solitary mountain of sandstone rises 1400 feet almost perpendicularly: the surface is more than a mile in circumference. But the fortress is of no military importance, as it cannot serve for a rallying point or point of support for an army, nor impede the march of an enemy. It is very useful, however, as a place of deposit for precious articles, for instance, the invaluable pictures of the Dresden gallery, in times of war. It cannot be undermined, nor can it be reduced by cutting off its supplies, as the small garrison necessary to hold it, can raise grain enough for their subsistence on the top of the mountain. There is a well 1172 feet deep. About 600 people reside on the top. The cannon of the fortress command the town below it on the river Elbe. The Lillienstein (q. v.) is opposite.

**KOPECK**; a Russian coin. See *Copeck*, and *Coin*.

**KOPF**; German for *head*; appearing in many geographical words, for *summit*; also *koppe*.

**KORAIS**. See *Coray*.

**KORAN** (*Al-Koran*, i. e. the *Koran*, which means originally the *reading*, or that which is to be read; also called *al Forkan*, because it is divided into 114 *suras* or chapters; also *al Moshaf*, the volume; *al Kibla*, the book; *al Dhikr*, the recollection) is the religious code of the Mohammedans, written in Arabic by Mohammed. The parts were collected into a volume by Mohammed's father-in-law and successor, Abubekir. According to the Mohammedan doctrine, the prophet received the Koran from the angel Gabriel, written upon parchment made of the skin of the ram which Abraham sacrificed in the name of his son Isaac. The volume was ornamented with precious stones, gold, and silver, from Paradise. According to other traditions, Mohammed is said to have drawn up the Koran with the assistance of a Persian Jew, rabbi Warada Ebn Nawsal, and a Nestorian monk, the abbot of the convent of Addol Kaist, at Bosra, in Syria; but nothing certain is known respecting these two persons, though it appears beyond a doubt, less from the author's doctrines than from the expressions, his tales, and his mentioning several prophets, &c., that he was well acquainted with the Old and New Testament, though he himself cites only the Pentateuch and the Psalms. In the twenty-first chapter, he represents the Almighty as saying, "I have promised in the books of Moses and in the Psalms, that my virtuous servants on earth shall have the earth for their inheritance." A number of passages might be quoted which prove his knowledge of the whole Bible; and not only was he acquainted with the religious systems of the Jews and Christians, but also with those of the Sabæans and Magians, from all of which he seems to have drawn materials which he incorporated into a system, after he idea of establishing a religion in his country, where numberless sects of pagans, Jews, Christians, Sabæans, and Magians existed, had risen in his mind. He lived, as is well known, much in solitude, where

he doubtless meditated on his doctrine, and the great mission which he thought himself called upon to accomplish. He does not reject the doctrines of any sect, but takes from all. He asserts that he wishes to restore the true faith to its purity. The unity of God is his fundamental doctrine, which is clearly laid down in the symbol of the Moslem—"God is God, and Mohammed is his prophet." The unity of God is the very aim of his mission, and, according to him, had been the essence and the basis of all true religion, with which ceremonies and customs were only accidentally connected. Thus he says, in the eleventh chapter of the Koran, "We make no difference between that which God has taught us, and that which Abraham, Isaac, Ishmael, the twelve tribes, Moses and Jesus have learned from the Lord. We believe in God, and are Moslem." And, in the fourth chapter, it is said, "God commands thee to receive the religion which he prescribed to Noah, which he has revealed unto thee, and which he imparted to Abraham, Moses, and Jesus." Who can say whether it was the desire of establishing pure monotheism in his country, or ambition, which led him to call himself a prophet? But even in the way in which he speaks of his inspirations, we may discern an endeavour not to deviate from ideas already adopted, or, at least, the evidence of his being strongly influenced by them. He professed to have nocturnal intercourse with the angel Gabriel, who brought him the Koran precisely as it stands, verse for verse, chapter for chapter, from heaven. In the doctrine of the Magians, the angel Gabriel is the angel of revelation. Besides the fundamental doctrine of the unity of God, the Koran establishes several other articles of faith. Thus, in chapters four, six, seven, and forty-eight, the doctrine of good and bad angels is set forth, which was general with the Arabians before Mohammed. Mohammed returns most frequently to the doctrine of the resurrection and the last judgment. The way in which he endeavours to set it forth has much similarity with that of St Paul. He even borrows expressions from the Jewish and Christian scriptures, when he speaks of the last judgment. In chapter forty-three, it is said, "When the trumpet sounds the second time, they shall rise quickly from the graves to appear before God;" and further, "A sound of the trumpet of judgment will assemble all men before my throne, and every one shall there receive the reward of his deeds." In regard to the form of the last judgment, Mohammed followed the doctrines of the Jews and Magians; for instance, the passage of the narrow bridge *Al-Sirat* (q. v.), the book in which all the actions of men are set down, and the scale in which they are weighed. Mohammed's paradise, too, is quite Jewish and Magian. Another dogma is set forth in the Koran, yet not explicitly, that of the unchangeable decrees of God. Mohammed used the doctrine of predestination with great success, to infuse into his adherents undaunted courage, which elevated them above all perils. Probably he adopted, in this case, views already widely spread. With the Sabæans, the belief in predestination was firmly established, and founded on the unchangeable course of the stars, and their influence upon the life and actions of men and the course of events. With the Magians this doctrine followed from their system of the good and evil principles, and probably it had passed from both to the Arabians. In regard to religious exercises, too, Mohammed adopted such as he found, giving more universality and precision to those which were vague. The Koran prescribes prayer, fasting, alms, and the pilgrimage to Mecca. The first includes every thing relating to the purifications and ablutions, by which the faithful prepares himself for prayer. Mohammed

considered this exercise of the greatest importance. When the Tayesites sent an embassy to the prophet to request him to absolve them from the troublesome observance of this exercise, his answer was, "Religion is nothing without prayer." In another passage he calls prayer the "key to paradise." He surpassed the severity of the rabbis, and prescribed prayer five times a day, with the face turned towards Mecca. Turning the face, during prayer, toward a certain point, is a common custom with the Orientals. It was particularly so with the Jews, Sabæans, and Magians, who call the point to which they turn *kebla*. In the beginning, Mohammed adopted the same *kebla* with the Jews, i. e. the city of Jerusalem. In the second year, he changed the *kebla* to Mecca. The way which he prescribed for calling the people to prayer was at first that of the Jews and Christians, but he afterwards adopted another. To give alms, was always a particular trait of the Arabians, but Mohammed made it obligatory. The pilgrimage, or something similar, had existed with most sects before him. In respect to the civil laws, relating to polygamy, divorce, inheritance, &c., Mohammed followed step for step, the laws of Moses and the decisions of the rabbis, only adapting them to the customs and prejudices of his countrymen. As for the propagation of his religion, Mohammed only requires from converts the pronunciation of the words of his fundamental doctrine; he enjoins no abjuration, no violent separation from a former faith. To the Jews he says, that he only comes to restore the faith of their fathers in its purity; to the Christians, that Jesus is the best of prophets, and sometimes he wishes to pass with them as the Paraclete. Excepting the worship of idols, which was positively against his fundamental doctrines, he attacks few old customs; and, though he prohibits the use of inebriating liquors, and requires fasting, yet he says, "God intended that his religion should be easy, else, as he well knew, you would only become hypocrites"—a sentiment probably caused by the state of the Christian and Jewish sects, with which he was acquainted. The description of his paradise is voluptuous and glowing. The language of the Koran is considered the purest Arabic, and contains such charms of style and poetic beauties, that it remains inimitable. Its moral precepts are pure. A man who should observe them strictly, would lead a virtuous life. "From the Atlantic to the Ganges," says Gibbon, "the Koran is acknowledged as the fundamental code, not only of theology, but of civil and criminal jurisprudence; and the laws which regulate the actions and the property of mankind, are guarded by the infallible and immutable sanction of the will of God." The Koran repeatedly enjoins belief in one God, and implicit obedience towards him, charity, mildness, abstinence from spirituous liquors, toleration, and ascribes particular merit to death in the cause of religion. It is about equal in size to the New Testament. It differs greatly from the Bible by forming one whole, instead of being a collection of very different books, unconnected with each other. The divisions sometimes have strange inscriptions. Many elevated passages adorn the Koran, but it often becomes tedious by its repetitions. The Koran is daily read once through in the mosques of the sultan and the adjoining chapels. (See *Islam*, and *Mohammed*.) It was first printed by Alex. Paganinus Brixiensis, at Venice, according to some about 1509, according to others in 1518, or as late as 1530. In *Thesei Ambr. Albenensis Introd. in Chaldaic. Linguam* (Pavia, 1539), this edition is mentioned, and a passage cited, with reference to the sheet and the page; it has, therefore, certainly existed, but no copy is to be found in any library. The earliest edition, at present known,

is by Abr. Hinkelmann (Hamb., 1694, 4to); another, with a Latin translation (Padua, 1698, fol.); and another was published by order of Catherine II., by Mollah Usman Ismael (Petersburg, 1787, small folio; new edition, 1790, and 1793; reprinted, Kasan, 1809, fol.; another ed., Kasan, 1803, large 4to); Latin translations after that of Robertus Kettenensis (Ketenensis) (Bale, 1543, fol. new ed., Zurich, 1550, fol.); one also by Reineccius (Leipsic, 1711); an Italian translation, made after the Latin (Venice, 1547, 4to); French translations by And. de Ryer (Paris, 1649; Leyden, 1672, 12mo, and the Hague, 1683 or 1684, 12mo), with the introduction by Sale (2 vols., Amsterdam, 1770 or 1775, 12mo); by Savary, (Paris, 1782, 2 vols.; new ed., Amst., 1796, 2 vols.; and Paris, 1798 (an VII.); English version, by Sale (London, 1734, 4to, 1764, 1801, and 1812.) The edition of London (1649, 4to; new edition, 1688) is merely translated from the French translation of Du Ryer; German translation by Schweigger (Nuremberg, 1616; 2d edit., 1623). The Italian translation has been followed in that of Mezerius (Frankfort on the Maine, 1772), that of Boyssé (Halle, 1775), and that of Augusti (Weissenfels and Leipsic, 1798). A Dutch translation of the Koran appeared at Hamburg (1641), (after Schweigger's German Koran), and another by Glasemaker (Rotterdam, 1698). A *vocabularium* of the Koran was published by Willmet and Nodcockum ool Fourtan (Calcutta, 1811, 4to).

KORNACH, in the East Indies; an elephant driver and keeper.

KORNER, THEODOR; a German poet, particularly celebrated for the spirited poems which he composed in the campaign against Napoleon (1813, in which he fell. He was born in 1791. His father often received Schiller and Goethe in his house at Dresden. Korner first studied mining at Freyburg. In 1810, he went to the university of Leipsic, where his ardent temperament led him into acts of impudence, which obliged him to leave Leipsic. He went to Vienna, where he wrote several dramas. In 1813, when all Germany took up arms against Napoleon, Korner served in the corps of Lutze, a Prussian officer. In the battle of Kitten, he was severely wounded in the head, but recovered during the armistice, and, Aug. 26, 1813, fell on the first of battle, pierced by a ball. An hour before, he had finished his famous song, the Address to his Sword, and read it to his comrades. An iron monument shows the place where he rests under an oak tree, near the village of Wobbelin, in Mecklenburg. His father has published thirty-two of his war-songs, under the title *Leier und Schwert—Lyre and Sword* (Berlin, sixth edition, 1824). Many of these poems have been set to music by Weber, and, taken as a whole, are unique. They have all become national in Germany. Korner's father also published his other works.

KOSCIUSKO, THADDEUS, the last generalissimo of the republic of Poland, one of the noblest characters of his age, was descended from an ancient and noble, though not rich family, in Lithuania, and was born in 1756. He was educated in the mathematics school at Warsaw. The prince Adam Czartoriski, perceiving his talents and industry, made him second lieutenant in the corps of cadets, and sent him, at his own expense, to France, where he studied drawing and the military art. After his return, he was made captain. But the consequences of an unhappy passion for the daughter of Sosnowski, marshal of Lithuania (who was afterwards married to the prince Jos. Lubomirski), obliged him to leave Poland. Secondary studies, particularly in history and mathematics, and an elevated character, prepared him for the

struggle for freedom, in which he engaged under Washington, who made him his aid. He distinguished himself particularly at the siege of Ninety-Six, and was very highly esteemed by the army and the commander-in-chief. He and Lafayette were the only foreigners admitted into the Cincinnati. Kosciuszko received the rank of general, and, in 1786, returned to Poland. When the Polish army was formed (1789), the diet appointed him a major-general. He declared himself for the constitution of May 3, 1791, and served under prince Joseph Poniatowski. In the campaign of 1792, he distinguished himself against the Russians at Zielonek and Dubienka. At the latter place, under cover of some works which he had thrown up in the course of twenty-four hours, he repulsed, with 4000 men, three successive attacks of 18,000 Russians, who prevailed only after the loss of 4000 men. Kosciuszko retired without having suffered severely. When king Stanislaus submitted to Catharine, he, with sixteen other officers, left the army, and was, therefore, obliged to retire from Poland. He went to Leipsic; and the legislative assembly of France, at this time, gave him the rights of a French citizen. The Poles becoming impatient under the oppression of Russia, some of Kosciuszko's friends in Warsaw determined to make an effort for the liberation of their country. They chose Kosciuszko their general, and made him acquainted with their plans. He imparted them to the counts Ignatius Potocki and Kolontai in Dresden, who thought the enterprise injudicious. Kosciuszko, however, went to the frontier, and sent general Zajonczek and general Dzialynski into the Russian provinces of Poland, to prepare every thing in silence. But when the Polish army was merged, in part, in the Russian, and the remainder reduced to 15,000 men, the insurrection broke out before the time fixed on. In Posen, Madalinski forcibly opposed the dissolution of his regiment. All now flew to arms; the Russian garrison was immediately expelled from Cracow. Just at this moment, Kosciuszko entered the city. The citizens now formed the act of confederation of Cracow (March 24, 1794), and Kosciuszko, at their head, called upon the Poles to restore the constitution of May 3. Kosciuszko then advanced to meet the Russian forces. Without artillery, at the head of only 4000 men, part of whom were only armed with scythes and pikes, he defeated 12,000 Russians at Racławice (April 4, 1794). His army was now increased to 9000 men, and he formed a junction with general Grochowski. In the mean time, the Russian garrisons of Warsaw and Wilna had been put to death, or made prisoners. Kosciuszko checked the outbreak of popular fury, sent troops against Volhynia, and organized the government at Warsaw. He marched out of the city, with 13,000 men, to oppose 17,000 Russians and Prussians, attacked them at Szezakocini, June 6, but was defeated after an obstinate conflict. He retreated to his entrenched camp before Warsaw. The Prussians took Cracow. Disturbances broke out, in consequence, in Warsaw, June 28. The people murdered a part of the prisoners, and hung some Poles who were connected with the Russians. But Kosciuszko punished the guilty, and restored order. The king of Prussia now formed a junction with the Russians, and besieged Warsaw with 60,000 men. Kosciuszko, however, kept up the courage of his countrymen. After two months of bloody fighting, he repelled, with 10,000 men, a general assault. All Great Poland now rose, under Dombrowski, against the Prussians. This circumstance, together with the loss of a body of artillery, compelled the king of Prussia to raise the siege of Warsaw. Thus this bold general, with an army of 20,000 regular troops and

40,000 armed peasants, maintained himself against four hostile armies, amounting in all to 150,000 men. His great power consisted in the confidence which his fellow citizens reposed in him. The nephew of the king, once his general, served under him. Kosciuszko had unlimited power in the republic, but he displayed the integrity of Washington and the activity of Cæsar. He attended to procuring supplies, superintended the raising and payment of money, and prevented plundering and fraud, and was equally active in the council and the field. His days and nights, all his powers were devoted to his country. He secured the administration of justice, abolished bondage, and finally restored to the nation, May 29, in the supreme national council which he established, the great power which had been delegated to him. Catharine at length decided the contest by an overwhelming superiority of numbers. Suwaroff defeated the Poles under Sierakowski at Brzec, in Volhynia, September 18 and 19. Reppin penetrated through Lithuania, and formed a union with Suwaroff; general Fersen was to support them with 12,000 men. To prevent this, Kosciuszko marched from Warsaw with 21,000 men. Poninski was to have supported him with his division; but the Russians intercepted the messenger. The united Russian armies under Fersen attacked the Poles, who were not more than one third as strong as the Russians, October 10, at Macziewice (about fifty miles from Warsaw); they were three times repulsed, but, on the fourth attack, they broke through the Polish lines. Kosciuszko fell from his horse covered with wounds, exclaiming, "*Finis Polonia!*" and was made prisoner by the enemy. In losing him, his country lost all. Suwaroff stormed Prague, November 4; Warsaw capitulated on the 9th; Madalinski left Great Poland; an Austrian army appeared before Lublin. But the noble efforts of the conquered had awakened the regard of Europe towards the unhappy country, and the dearest hopes of the nation—the restoration of their monarchy, with a free constitution—found a powerful support in public opinion. Catharine caused the hero and his noble colleagues, who were prisoners of war, to be thrown into a state prison. Paul I. gave them their liberty, and distinguished Kosciuszko by marks of his esteem. He presented his own sword to the general, who declined it with these words—"I no longer need a sword, since I have no longer a country." To the day of his death, he never again wore a sword. Paul then presented him with 1500 peasants, and his friend Niemcewicz, the poet, with 1000. When on the Russian frontier, Kosciuszko declined this present by a letter. He and his friend now went by the way of France and London, where Kosciuszko was treated with distinction, to America (1797). His fortune was very small. On his return to his native country after the war of the revolution, he had received a pension from America, and he now found there such a reception as he deserved. In 1798, he went to France. His countrymen in the Italian army presented to him the sabre of John Sobieski, which had been found (1799) at Loretto. Napoleon afterwards formed the plan of restoring Poland to its place among the nations, and thus, at the same time, injuring Russia and extending his own power over the east of Europe. But Kosciuszko would take no part in this struggle, which was conducted by Dombrowski, in 1807 and 1808, being prevented less by ill health than by having given his word to Paul I. never to serve against the Russians. To Napoleon's proposals he answered, that "he would exert himself in the cause of Poland, when he saw the country possessed of its ancient territories, and having a free constitution." Fouché tried every means to carry him to Poland. An appeal to the

Poles, which appeared under his name in the *Moniteur* of November 1, 1806, he declared to be spurious. Having purchased an estate in the neighbourhood of Fontainebleau, he lived there in retirement till 1814. April 9, 1814, he wrote to the Emperor Alexander to ask of him an amnesty for the Poles in foreign lands, and to request him to become king of Poland, and to give to the country a free constitution, like that of Britain. In 1815, he travelled with Lord Stewart to Italy, and, in 1816, he settled at Soleure. In 1817, he abolished slavery on his estate of Siemowice, in Poland. He afterwards lived in retirement, enjoying the society of a few friends. Agriculture was his favourite occupation. A fall with his horse from a precipice, not far from Vevay, occasioned his death, October 16, 1817, at Soleure. He was never married. In 1818, prince Jablonowski, at the expense of the emperor Alexander, removed his body, which, at the request of the senate, the emperor allowed to be deposited in the tomb of the kings at Cracow. A monument was also erected to his memory, and the women of Poland went into mourning for his loss.

KOSEGARTEN, LOUIS THEOBALD, a poet and preacher, was born February 1, 1758, at Grevesmühlen, a small town of Mecklenburg, studied at Griefswald, was for a long time a tutor in the family of a nobleman in Pomerania, became, in 1792, a preacher at Altenkirchen, in the island of Rugen, and was made, in 1793, doctor of theology. Upon this patriarchal island he lived in the enjoyment of nature, his family, poetry, literature, and in a faithful discharge of the duties of his office, a number of happy years, till he received, in 1807, an invitation to a professorship at Griefswald. He died there, October 26, 1818, rector of the university, in the sixty-first year of his age. The fruits of his leisure hours—his romances, for instance, *Ida von Plessen* (2 vols.); his rhapsodies, his legends, his epic-idyllic poems *Jukunde*, and *Inselfahrt*; his patriotic songs; several translations, of which Richardson's *Clarissa* is the most distinguished—have obtained for him no mean rank in German literature. His muse, often full of natural power and fire, frequently runs into bombast and prolixity. His collected poems appeared at Griefswald, 1824, in twelve volumes.

KOSLOFF, IWAN, a Russian nobleman, born about 1780, passed his youth in the great world. In the social circles of the nobles of Moscow and St Petersburg, he led an animated, rather than a busy life. His genius was not as yet awakened; still he loved literature, was master of the French and Italian languages, and familiar with their classics. But he had recourse to these studies only when in want of occupation, and to recruit his mind exhausted by dissipation. His activity was mainly devoted to the pleasures of this world, and the care of his family. When about forty years old, he was attacked with a severe sickness, which deprived him of the use of his feet. Removed thus at once from the company which he loved, loneliness compelled him to seek in himself an indemnification for the loss of worldly pleasure. This stroke did not prostrate him: on the contrary, his mind took a higher flight. He became a poet. The ideal world which he now inhabited indemnified him fully for the reality of which he was deprived. Upon his bed of pain he learned to know himself, and discovered in himself a talent hitherto unknown to him. In a short time he made himself familiar with the English language and literature. Yet a more severe trial awaited him: he lost his sight. This misfortune did not depress his courage: on the contrary, he made it a means of moral and spiritual elevation. With his blindness burst forth his poetic spirit. He soon commenced

the study of the German language, and made himself acquainted with the classical poetry of Germany. Since then Kosloff has lived in the world of recollection and of fancy. He is endowed with an extraordinary memory, and retains every thing which he learns. He writes poetical epistles to his friends, who gather around him, not to cheer him, but to delight themselves with his conversation. This providence which veiled his eyes, said to his soul, "Let there be light." His conversation is rich and full of spirit. Notwithstanding the trifling character of his early life, he takes a lively interest in all that is noble, great, and manly. Kosloff has made some very good translations from English and Italian poetry. His *Monk*, in poetic power, reminds one of Byron's *Glaour*. His translation of the *Bride of Abydos* was published at St Petersburg, 1826. Kosloff has of late been employed on a great work, the materials of which are taken from Russian history, at the time of the empress Anne.

KOTTAH (Sanskrit, for *dwelling*); the ending of a great number of Hindoo geographical names, like the German *Heim* (q. v.) and the English *ham*. (q. v.)

KOTZEBUE, AUGUSTUS FREDERICK FRIEDRICH VON, a prolific German writer, was born May 3, 1761, at Weimar. At the age of sixteen years he entered the university of Jena, where his inclination for drama, already awakened at Weimar by the celebrated company of players in that city, was confirmed by his connexion with a private theatre. The marriage of his sister to a gentleman of Duisburg induced him to enter the university, then at that place; but, in 1779, he returned to Jena, and studied law; without, however, ceasing to compose for the theatre. On leaving the university he was admitted a lawyer. He imitated Schiller, Goethe, Wieland, Herder, Brandes, and Musæus. In 1781, he went to St Petersburg, at the suggestion of the Prussian minister at that court, and became secretary to the governor-general, Von Bawr, who died two years afterwards. He had, however, recommended Kotzebue to the empress, and she became his patroness. He was finally appointed president of the government of Esthonia, and, as such, was ennobled; in consequence of which he wrote his work *On Nobility*, in which he defended this institution, after having often attacked it as a poet. In 1790, on a journey to Pyrmont, he published his notorious *Doctor Bahrdt and the Iron Forehead*, under the name of Knigge, by which he sank greatly in public esteem. In 1793, he retired to a country place about thirty-five miles from Narva, in Esthonia, but soon after removed to Weimar, with a pension of 1000 guilders, and again returned to Petersburg, where his sons were educated in the imperial military school. Although he had a passport, yet, on his arrival at the frontier, he was arrested, and sent to Siberia, without learning the reason. A small drama of his, an indirect subject of Paul I., was translated into Russian, and had a manuscript, before the emperor, who was so delighted with it, that he recalled Kotzebue, and took him into favour. After the death of this emperor, he again went to Germany. In 1802, he was chosen member of the academy of sciences of Berlin,—by what intrigues we do not know,—and, with Merkel, formed a party against Goethe and Schlegel, in which contest the latter, of course, were much superior. In 1803, he went again to Russia, to avoid the French, and lived, from 1807, on his estate Schwartzau, in Esthonia, never ceasing to write against Napoleon. In 1813, as counsellor of state, he followed the Russian head quarters, constantly writing to excite the nations against Napoleon, and published, in Berlin, the Russian-German National Gazette (*Volkshaus*

In 1814, he produced a very poor history of the German empire. He had already proved himself totally unfit for a historian by his Early History of Prussia (Riga, 1809). In 1817, he received a salary of 15,000 roubles, with directions to reside in Germany, and to report upon literature and public opinion. Kotzebue, who, during the whole campaign, had written in favour of the Russians, even at the expense of his native country, was now considered by most Germans as a spy. He established the Literary Weekly Paper, in which he passed judgment on the publications of the day, and advanced political opinions equally dishonourable and obnoxious to Germany, ridiculing every attempt at liberal institutions. The state of things before the French revolution, was his standard of perfection. Kotzebue was regarded with aversion by the liberal party in Germany, as an enemy to the freedom of his country; and among the young and ardent, his ridicule of their noblest sentiments and most cherished hopes awakened bitter hatred. This feeling was so strong in the case of a young enthusiast named Sand (q. v.), that he formed the plan of putting Kotzebue to death, as the enemy of his country, and deliberately murdered him, March 23, 1819, after which he immediately gave himself up to justice. Kotzebue was three times married, and left thirteen children. His best productions are his comedies, which seem to be much more popular with foreigners than with Germans. A sickly sentimentality in his graver dramas, and the insipidity of his comedies, are seldom redeemed by higher excellences. He wrote ninety-eight dramas. As an historian, he deserves to be mentioned only for a few documents reprinted in his Prussian History.

KOULI KHAN. See *Nadir Shah*.

KOURD; strong, robust; a Persian word. Hence the name of *Kurdes*, *Kourdes*, or *Curdes*, and *Curdestan*.

KRAKEN, KRAXEN or, as some call it, KRAB-BEN; that word, says Pontoppidan, bishop of Bergen, being applied, by way of eminence, to the fish otherwise called *horven*, *soe-horven*, *anker-troll* and *krausfisch* "incontestably," as observes the same naturalist (whose description of it we shall give in a translation of his own words), "the largest sea-monster in the world. It is round, flat, and full of branches. The Norwegian fishermen unanimously, affirm, and without the least variation in their accounts, that, when they row out several miles to sea, particularly in the hot summer days, and, by their situation (which they know by taking a view of certain points of land), expect to find 80 or 100 fathoms water, it often happens that they do not find above twenty or thirty, and sometimes less. At these places, they generally find the greatest number of fish, especially cod and ling. Their lines, they say, are no sooner out, than they may draw them up with the hooks all full of fish; by this, they judge that the kraken is at the bottom. They say this creature causes these unnatural shallows mentioned above, and prevents their sounding. These the fishermen are always glad to find, looking upon them as a means of their taking abundance of fish. There are sometimes twenty boats or more got together, throwing out their lines at a moderate distance from each other, and the only thing they have to observe is, whether the depth continues the same, which they know by their lines, or whether it grows shallower, by their seeming to have less water. If this last be the case, they find then the kraken is raising himself nearer the surface, and then it is no time for them to stay any longer; they immediately leave off fishing, take to their oars, and get away as fast as they can. When they have reached the usual depth of the place, and find themselves out of danger, they lie upon their oars, and, in a few minutes

after, they see this enormous monster come up to the surface of the water. He there shows himself sufficiently, though his whole body does not appear, which, in all likelihood, no human eye ever beheld, excepting in the case of one of the young of this species, which shall afterwards be spoken of. Its back or upper part, which seems to be in appearance about an English mile and a half in circumference—some say more, but I choose the least for greater certainty—looks at first like a number of small islands, surrounded with something that floats and fluctuates like sea-weed. Here and there, a large rising is observed, like sand-banks, on which various kinds of small fishes are seen continually leaping about, till they roll off into the water from the sides of it. At last, several bright points or horns appear, which grow thicker and thicker the higher they rise above the surface of the water, and sometimes they stand up as high and large as the masts of middle-sized vessels. It seems these are the creature's arms; and it is said, if they were to lay hold of the largest man-of-war, they would pull it down to the bottom. After this monster has been on the surface of the water a short time, it begins slowly to sink again; and then the danger is as great as before, because the motion of his sinking causes such a swell in the sea, and such an eddy or whirlpool, that it draws every thing down with it." The arms above described are conjectured to be tentacula, and the kraken itself to be an enormous polypus. Besides these arms, "the great Creator has also given this creature a strong and peculiar scent, which it can emit at certain times, and by means of which it beguiles and draws other fish to come in heaps about it." During many months, the kraken is continually employed in eating; during many others, in carrying on the very last process which succeeds digestion; and this operation is so peculiarly agreeable to the "smell and taste of other fishes, that they gather together from all parts to it, and keep for that purpose directly over the kraken: he then opens his arms or horns, seizes and swallows his welcome guests, and converts them, after the due time, by digestion, into a bait for other fish of the same kind. I relate what is affirmed by many; but I cannot give so certain assurance of this particular as I can of the existence of this surprising creature, though I do not find any thing in it absolutely contrary to nature. As we can hardly expect an opportunity to examine this most enormous sea-animal alive, I am the more concerned that nobody embraced that opportunity, which according to the following account, once did, and perhaps never more may offer, of seeing it entire when dead. The reverend M. Friis, consistorial assessor, minister of Bodoen, in Nordland, and vicar of the college for promoting Christian knowledge, gave me, at the latter end of last year, when he was at Bergen, this relation, which I deliver again on his credit. In the year 1680, a kraken, perhaps a young and careless one, came into the water that runs between the rocks and cliffs in the parish of Alstahoug, though the general custom of that creature is to keep always several leagues from land, and therefore, of course, they must die there. It happened that its extended long arms or antennæ, which this creature seems to use like the snail, in turning about, caught hold of some trees standing near the water, which might easily have been torn up by the roots; but, besides this, as it was found afterwards, he entangled himself in some openings or clefts in the rock, and therein stuck so fast, and hung so unfortunately, that he could not work himself out, but perished and putrefied on the spot. The carcass, which was a long while decaying, and filled great part of the narrow channel, made it almost impassable by its intolerable stench." The animal seen by

the reverend Donald Maclean, of Small Isles, and attested by him in a letter to the Wernerian Natural History Society of Edinburgh, though not quite so large as the Norwegian kraken, certainly tends to confirm a belief that, with due allowance for exaggeration, monsters of a larger size than philosophy has dreamed of, really do exist in the northern seas, or, in the well-expressed phrase of doctor Barclay, in his paper relating to this animal, that there are "grounds sufficient to awaken the curiosity of naturalists, who, it were to be wished, were always men of accurate discrimination and sound judgment, not prone to indulge in a passion for the marvellous, nor apt to be infected with the silly conceit, that their knowledge of nature is already so complete, that little of importance remains to be discovered." (*Transactions of W. N. H. S.*, 430.) Mr Maclean's account is not a little curious. "According to my best recollection," says he, "I saw it in June, 1808, not on the coast of Eigg, but on that of Coll. Rowing along that coast, I observed, at about the distance of half a mile, an object to the windward, which gradually excited astonishment. At first view, it appeared like a small rock. Knowing there was no rock in that situation, I fixed my eyes on it close. Then I saw it elevated considerably above the level of the sea, and, after a slow movement, distinctly perceived one of its eyes. Alarmed at the unusual appearance and magnitude of the animal, I steered so as to be at no great distance from the shore. When nearly in a line betwixt it and the shore, the monster, directing its head, which still continued above water, towards us, plunged violently under water. Certain that he was in chase of us, we plied hard to get ashore. Just as we leaped out on a rock, taking a station as high as we conveniently could, we saw it coming rapidly under water towards the stern of our boat. When within a few yards of the boat, finding the water shallow, it raised its monster-head above water, and, by a winding course, got, with apparent difficulty, clear of the creek where our boat lay, and where the monster seemed in danger of being embayed. It continued to move off with its head above water, and with the wind, for about half a mile, before we lost sight of it. Its head was rather broad, of a form somewhat oval; its neck somewhat smaller; its shoulders—if I can so term them—considerably broader; and thence it tapered towards the tail, which last it kept pretty low in the water, so that a view of it could not be taken so distinctly as I wished. It had no fin, that I could perceive, and seemed to me to move progressively by undulations up and down. Its length I believed to be from seventy to eighty feet. When nearest to me, it did not raise its head wholly above water, so that, the neck being under water, I could perceive no shining filaments thereon, if it had any. Its progressive motion under water I took to be rapid, from the shortness of time it took to come up to the boat. When the head was above water, its motion was not near so quick; and when the head was most elevated, it appeared evidently to take a view of distant objects. About the time I saw it, it was seen about the island of Canna. The crews of thirteen fishing boats, I am told, were so much terrified at its appearance, that they, in a body, fled from it to the nearest creek for safety. On the passage from Rùm to Canna, the crew of one boat saw it coming towards them with the wind, and its head above water. One of the crew pronounced its head as large as a little boat, and each of its eyes as large as a plate. The men were much terrified, but the monster offered them no molestation." (*Id.* 442).—The appearance described by Mr Maclean calls to mind the sea-serpents which have been so often reported, of late years, as seen on the coast of New

England. Whatever may be the animal which has given rise to these stories, the kraken described by Pontopidan can hardly be supposed to be a real existence. The story probably grew out of the appearance of islands which have risen above the surface of the sea, and become again submerged, or of rocks only visible at particular seasons, or of floating islands, &c. The young kraken which he describes was probably some large sea-monster, whose appearance had become much exaggerated in the course of narration.

KRANACH, LUCAS. His proper name was *Sunder* or *Sünder*, but he was called *Kranach*, from the place where he was born (1472), in the bishopric of Bamberg. He went to Coburg, after having learned a little of the art of painting from his father, who was a form-cutter and card painter. The elector Frederic the Wise admitted him to his court. He accompanied him on his journey to Palestine, in 1500. In 1504, he was appointed painter to the elector and his brother, duke John Frederic, was made a knight, and, in 1537, burgomaster of Wittenberg, accompanied the elector John Frederic in his captivity to Inspruck, returned with him, and died in 1553, at Weimar. He painted much, and the good part of the stone-cutter, who put on his tomb-stone *pater celerrimus* (the quickest painter), instead of *pater celerrimus* (the most famous), was not inappropriate.—His son, of the same name, who was also burgomaster at Weimar, where he died in 1586, may have painted many of the pieces ascribed to *Kranach*. We are most indebted to *Kranach* for his portraits of Luther, Melancthon, and other persons, famous at the time of the reformation. His historical paintings always seemed to us dull histories indeed, and his numerous representations of Adam and Eve are little better than libels on the work of creation.

KRASICKI, IGNATIUS, count of Sietona, archbishop of Gnesna, a poet and author, was born at Dubiecko, February 3, 1735. When the partition of Poland, in 1772, obliged him to give up his office in the senate of the republic, he turned his attention to science. He excelled in describing the ridiculous in the national customs of his country. His conversation was agreeable and witty. Frederic the Great once said to him, "I hope, Mr Archbishop, you will carry me through your episcopal cloak into Paradise."—"No, sire," answered *Krasicki*, "your majesty has cut it too short, that it will not serve for smuggling." Among the works of this poet are his mock-heros, *poema Le Mychide*, or *La Souviade*, in ten cantos, translated into French, the subject of which is from the ancient chronicle of bishop Kadlabek, which describes how mice and rats ate up king Popiel; also his *War of the Monks (La Monomachie)*, in six cantos, perhaps his masterpiece. Frederic the Great is said to have induced him to write it, when he lodged him in the room in Sans Souci, where Voltaire had lived, with the intimation that it would doubtless inspire him with poetical ideas. His *Antimonomachie*, also a six cantos, has less merit. Several of his fables are classic; not so his satires. The *War of Chacma*, a twelve cantos, describing the victory of Chacma over Sultan Osman, under the reign of Sogianus, has too much of an historical character. His poems are full of spirit. The writings of *Kranach* are classical among the Poles. He died at Butta, March 14, 1801. *Dmachowski* collected most of his works, and published them at Warsaw, 1803 in six ten volumes.

KREML, in the Tartar language, signifies a fortress. Hence the name of *Kremlin*.

KREMLIN; part of Moscow, in the centre of the city, containing only the royal edifices and churches, particularly the residence of the emperor. It is an

rounded by three thick walls and a deep fosse, with batteries. In the Kremlin are two convents, and many churches, particularly the cathedral, in which the coronation of the Russian emperors is performed. In the church of the archangel Michael is the sepulchre of the emperors, and behind it the house of the former patriarch, where the synod now assembles, and a library is kept, which is rich in Greek and Russian manuscripts. In the castle, the imperial colleges have their sessions; the arsenal is also there. In 1812, when Moscow was burnt by the Russian authorities, part of the Kremlin was also destroyed. When Napoleon left Moscow, marshal Mortier received orders to blow it up. Alexander restored it.

KREMnitz. See *Cremnitz*.

KRONSTADT. See *Cronstadt*.

KRUDENER, JULIANA, baroness of; born about 1766, in Riga. Her father, baron Vietinghoff, one of the richest landed proprietors in Courland, gave her a careful education. When a young girl, her parents took her to Paris, where her father's house was the resort of men of talents, and her wit, beauty, and cheerfulness were admired. In her fourteenth year, she was married to baron Krudener, a Livonian, about thirty-six years old. She accompanied her husband to Copenhagen and Venice, where he was Russian minister. In these places, and in Petersburg, Madame Krudener, placed by rank and wealth in the first circles, was one of their most brilliant ornaments. She was surrounded by admirers of her talents and beauty; but she was not happy. She became the mother of two children; but, as she herself indicates in a letter to her son-in-law, her natural liveliness of temperament and the allurements of the world led her into levities, which finally caused a divorce from her husband. In 1791, she returned to her father's house in Riga, where she was universally considered one of the most amiable and accomplished ladies, with a feeling heart and lively imagination. But Riga did not satisfy her, and she lived alternately in Paris and Petersburg in Russia. Her love of dissipation involved her, in Paris as well as in Petersburg, in many difficulties. In the former place, the fierce Garat is said to have been master of her heart. In the midst of these circumstances, she wrote a novel, of which she had formed the plan at an earlier period, *Valérie, ou Lettre de Gustave de Linar à Ernest de G.*, in which she delineated certain scenes of her own life. The disasters of Prussia arrived, and Madame Krudener, being then about the person of the queen of Prussia, and participating in her affliction, turned her mind from the pleasures of the world to the subject of religion, though, perhaps, as is often the case, little change may have been produced in the essentials of her character. Ambition, a lively sensibility, and love of excitement, seem to have remained the great springs of her actions. She was now attracted by the principles of the Moravians. She again went to Paris, where she found many disciples—a fact easily explained, from the circumstance, that the highest circles of Paris always contain a number of persons who, having been accustomed to live on excitements from early youth, and having become sickened with those of fashionable life, turn with pleasure to those of devotion. On the commencement of the war of the northern powers against Napoleon, Madame Krudener went to Geneva (1813). At Carlsruhe, she became connected with the mystical Jung (q. v.) She began to believe herself called to preach the gospel to the poor. She therefore went into the prison at Heidelberg, and preached to the criminals condemned to death. In 1814, she returned to Paris. Here she became acquainted with Alexander, emperor of Russia, who had already for some time shown a disposition to religious contem-

plations. According to a late publication of a companion of Madame Krudener, M. Empeytas, her conversations with the emperor had a great influence on him. In Paris, she had prayer-meetings, attended by distinguished personages, where she was seen in the background of a suite of rooms, in the dress of a priestess, kneeling in prayer. It is very generally believed, that her conversations, in Paris, with Alexander, were mainly instrumental in suggesting the idea of the holy alliance (q. v.); it is certain, that, in her later sermons, she held it up almost as a new covenant. She gave a description of the feast celebrated by the Russian army in the plains of Chalons, under the title *Le Camp de la Vertu* (Paris, by Normand), in which she gives her views respecting the history of the time. In 1815, she went to Bale, where a small community of devout mystics was already collected. Here a young clergyman of Geneva, the above-mentioned Empeytas, followed her, and preached in the prayer-meetings which the baroness held every evening. Women and girls went ardently to these prayer-meetings, and gave liberally to the poor, often to a degree much beyond what they could afford. These meetings, as is too often the case under circumstances of similar excitement, had a bad moral effect. Cases were reported which excited great scandal, and a preacher named Fasch finally denounced the priestess. The magistracy of Bale obliged her to leave the city. She experienced the same treatment in Lorrach, Arau, &c.; yet, according to the common course of things, the number of her followers increased, particularly among young females. At the same time she carried on an extensive correspondence; money was sent her from great distances. In 1816, with her daughter, she went to reside not far from Bale, in Baden, on the Horn of Grenzach. Besides M. Empeytas, she was accompanied by professor Lachenal, of Bale, and a Mr Kellner. Here she assembled many poor people, great numbers of whom were vagabonds, whom she provided with food and lodging, without labour. These were very ready to profit by the kindness of the good, benevolent lady, who preached against the cold-heartedness of the rich, as the source of all evil. The public peace was so much disturbed by these proceedings, that the Horn was surrounded by soldiers in 1817, and the disciples of Madame Krudener carried away to Lorrach. She wrote, in consequence, a remarkable letter to the minister at Carlsruhe, in which she spoke of the "desert of civilization" through which she was obliged to wander, and reminded him of the law of God, requiring the authorities to take care of the poor. She now travelled about, preaching in the open air, often surrounded by 3000 people, and giving bountifully to the poor. Wherever she arrived, she was under the surveillance of the police. In Leipsic, police officers were at length even placed at her door, so that nobody could be admitted to see her. Mr Krug, professor of philosophy in the university of that city, published *Gespräch unter vier Augen mit der Frau von Krudener* (Leipsic, 1818), according to which she appeared as an estimable enthusiast, pouring out pious effusions, mingled with arrogant prophecies. At length the police transported her to the Russian frontier, where she received orders not to go to Petersburg, nor to Moscow. In 1824, she went, with her daughter and her son-in-law, to the Crimea, and died there the same year, December 13, at Karafubasar. Madame Krudener is one more instance that ardent zeal and good intention (for it is probable that she considered herself to be doing right) are by no means sufficient to render one capable of effecting a great reformation.

**KRUNITZ**, JOHN GEORGE, physician at Berlin, was born 1728, studied at Göttingen and at Frankfurt on the Oder. In 1759, he returned to Berlin, devoted his whole life to literary pursuits, and died in 1796. A great number of useful publications upon medicine, natural history, geography, and other subjects, original and translated from various languages, are the fruits of his industry. His chief work is the (*Ökonomisch-technologische Encyclopädie*, which he began in 1773. It amounted to seventy-three volumes, and had just reached the article *Leiche* (corpse), when he was removed by death. The work is valuable, as containing much matter carefully selected. There is, however, a want of method and proportion in it. After his death, the brothers Florke, and, since 1815, J. W. D. Korth, have continued the work, which, in 1828, amounted to 142 volumes, and reached as far as *SCH*. The abridgment of the large work, thus far, amounts to 32 volumes.

**KUH**, EPHRAIM MOSES, born 1731, of Jewish parents, showed early uncommon strength of memory, vivacity of mind, and a restless desire of knowledge. His father, a rich trader, intended at first to educate him in Jewish learning; and, when the result by no means answered his expectations, he desired to make him a merchant. He allowed him to receive instruction in the French, Italian and English languages, by which means he attained a knowledge of modern literature and poetry. After his father's death, he went to Berlin, as first clerk in the counting-house of his uncle. Here his talents gained him the friendship of Mendelssohn, Ramler, Lessing, and other learned men, by intercourse with whom his poetical talent began to be developed. He possessed considerable property, besides a good salary; but his easy good nature, which made him often the prey of the fraudulent, united with an extravagant love of books, in a few years exhausted his means. He left Berlin, travelled through Holland, France, Italy, Switzerland, and Germany, and became, at last, dependent on his family. These circumstances produced in him a fixed melancholy, which at length increased to insanity, from which he was restored only by the activity of a skilful physician. In his lucid intervals, he produced the best of his poems. In 1785, he was deprived of strength and speech by apoplexy, in which state he died, 1790. Posthumous Poems, by Ephraim Moses Kuh, appeared at Zurich, in 1792.

**KULM**. See *Culm*.

**KUNERSDORF**. See *Cunersdorf*.

**KURDS**. See *Curds*.

**KURILES**; a long range of small islands at the eastern extremity of Asia, extending from the southern point of Kamtschatka to the isle of Jesso, or Matsmai, which belongs to Japan. The whole length of the chain amounts to nearly 900 miles. Some of the islands are not inhabited, and several are even uninhabitable, on account of the absolute want of water. Others are fertile, well wooded, full of game and fish. Some contain volcanoes; and they are all subject to frequent earthquakes. The number, without reckoning Jesso, is twenty-five. They were successively discovered, in the eighteenth century, by the Russians, and have been accurately known only since Krusenstern's voyage. The inhabitants are perhaps a thousand, and are known by the name of *Kuriles*, which is applied also to the people of the neighbouring coasts of Asia, and of the southern part of Kamtschatka. They are heathens, and some of them resemble, in language, shape, and manners, the Japanese. Others, on the contrary, resemble the people of Kamtschatka, many of whom, on the conquest of Kamtschatka by the Russians, fled to the

Kurile islands. Some of the islands have inhabitants descended from each of these stocks. The southern Kuriles are under Japanese government: the northern (21), on the contrary, are subject, in some measure, to Russia, and furnish, mostly under compulsion only, a tribute of sea-otter skins, fox skins, and other peltry. The chain extends from lat. 42° to 51° N.

**KUTUSOFF** (GOLENISSCHTSEFF, prince Smolensky), a Russian field-marshal, was born in 1745, entered the army in 1759, served in Poland from 1764 till 1769, and afterwards against the Turks, under Romanoff. He stormed the fortress Smolensk, and, at a later period, contributed greatly to the subjugation of the rebel Pugatschew. In 1788, he was present at the siege of Oczakow, having been appointed governor-general of the Crimea the year before. At the siege of Oczakow, he was wounded near the right eye. He assisted the prince of Coburg to gain the victory of Fockschani, and, in the memorable conflict of Rimnik, December 31, 1790, he performed miracles of bravery. After the storming of Ismail, under Suwaroff, he was advanced to the rank of lieutenant-general, and, in the negotiations with Turkey, which took place shortly after, he gained the fame of an able diplomatist. In 1793, he was appointed ambassador at Constantinople, and, in the subsequent Polish war, we find him in the Russian army, under Suwaroff. He was particularly conspicuous during the memorable day of Fraustadt (q. v.). After the restoration of peace, Kutusoff was first appointed commander-in-chief of Finland; but afterwards named him governor-general of Lithuania. He resided several years at Wilna, and endeavored to retrieve, by study, the deficiencies of his early education. For a short time, he filled the situation of ambassador to Berlin, but soon returned to Wilna, to his governor-generalship. After this, he was appointed chief of the corps of cadets, and, in 1801, governor-general of St Petersburg. In 1805, when he was at the age of sixty, the emperor Alexander gave him the chief command of the first Russian corps against the French. He led it towards the Inn, but did not arrive there until after the capitulation of Ulm, upon which he united himself with the small Austrian corps of general Kienmayer, and checked the whole of the French army. On the right bank of the Danube, to which he had crossed over, he was closely pursued by the French, and had several engagements with them, especially that near Durnstein, where he encountered marshal Mortier, on the 18th and 19th November, the issue of which contest was fortunate for him. The emperor of Germany sent him, on this occasion, the grand cross of the order of Maria Theresa. Hereupon, having joined the other Russian corps, he commanded the allied army, under Alexander, at Austerlitz, where he was wounded. In the Turkish war, he received orders from Alexander to close the campaign on the Danube. This being done, Kutusoff returned to Russia, and, when Barclay de Tolly resigned the command, after the first retrograde movement, he received, at the age of seventy, the chief command of the Russian army, in the war of 1812. After the battle of Mosaik, he adopted a new plan of warfare (See *Russian-German War*). To commemorate his victories, he received from Alexander the surname of *Smolenski*. Foreseeing the fate which awaited the retreating enemy on the banks of the Beresina, he pursued but slowly, and the campaign was already at an end, when he reached Wilna, where he received his emperor. This campaign had exhausted Kutusoff's strength. He was not in favour of a continuation of the war; for to him, a man beyond seventy years of age, it appeared too bold an enterprise to attack the enemy in the seat of his power. After having

the celebrated Russian proclamation from Kalisch, he died at Buntzlau, April 28, 1813. After the death of his widow, the emperor continued the pension of 86,000 roubles annually to her five daughters.

KUYP, or CUYP, ALBERT, a painter of great originality and merit, was born at Dort, in 1656. He was the son of an able landscape painter, whom, however, he far exceeded, and became one of the most agreeable artists that ever lived. He particularly excelled in the purity and brilliancy of light; and he was not surpassed, even by Claude or any other painter, in an accurate representation of the atmosphere, and of the lightsome effects of sunshine. The works of this artist, of whose life very little is known, embellish some of the finest collections in Britain; and as they are very highly finished, that circumstance, added to the number of them, implies a long life. The gallery of the marquis of Stafford, in particular, contains some highly valued pictures by Kuypp.

KYAU, FREDERIC WILLIAM, BARON OF; remarkable as a man who owed his success to his wit. Kyau was born in 1654, and, when seventeen years old, entered

the Brandenburg army, in which he rose, after ten years, to the rank of ensign. Some imprudences obliged him to leave Brandenburg. He went to Saxony, where the elector and king of Poland, Augustus II., became acquainted with his humour, took him into favour, made him his aid-de-camp, and, at length, adjutant-general and commandant of Konigstein (q. v.), which he always used to call his *stone wife*. He remained faithful to her until his death, in 1733. He was an honest man, hating all flattery. He was a real scourge of the court nobility. There are two biographies of this man, whose memory is still popular in the north of Germany, and of whom a thousand sayings are afloat among the people.

KYRLE, JOHN; surnamed by Pope the *man of Ross*; an English gentleman, who possessed an estate of £500 a-year, at Ross, in Herefordshire, where he died in 1754, at the age of ninety. Doctor Warton, in his *Essay on the Writings and Genius of Pope*, says Kyrle was the Howard of his age, and that he deserved to be celebrated beyond any of the heroes of Pindar. The splendid eulogium of the poet on the man of Ross is well known.

## L

L, in the English alphabet; the twelfth letter and the eighth consonant; one of those called *liquids*, or *semi-vowels*, because, like vowels, they may be pronounced for any length of time, which is not the case with the other consonants, called *mutes*, as, for instance, *p. k*. The sound represented by *l* is produced by placing the end of the tongue against the fore part of the roof of the mouth, opening the jaws, and gently breathing out the air, which thus escapes from the corners of the mouth. The pronunciation of *l*, therefore, is not dependent upon the teeth; yet there are individuals, and even whole tribes, who do not pronounce it; the former in consequence of some defect in their tongue; the latter, because they always use *r* instead of *l*, whilst others always use *l* instead of *r*. It must be observed, that the rolling *r* is different from the *l* only in this, that the former is pronounced with a vibration of the tongue. Hence the constant interchange of *r* and *l*, in many languages, which it is important for the etymologist to observe. Thus the French *orme*, from the Latin *ulmus*; from the Latin *peregrinus*, the Italian *pellegrino*, the French *pelerin*, the German and English *pilgrim*. Of the German word *kirche* (Scotch, *kirk*), the Swiss make *kilche*. The much more frequent change, we presume, is from the *r* to the *l*, as from the more difficult to the easier, yet not always. Thus the lower classes in Rome say, instead of *repubblica*, *republerica*. How frequent the change of *λ* and *ε* is, in Greek, particularly in the Ionian dialect, every philologist knows. In Greek, the letter was called *lambda*, analogous to the *lamed* of the Phœnicians and the Hebrews. It is remarkable, that, in all these alphabets, and in the Celtic ones, *l* is always composed, in some way, of two straight lines. We find, in most ancient Greek alphabets, the lambda *λ*, *Λ*, *λ*; in the Etruscan alphabet, *λ*; in the Celtic, *λ*, *λ*. The Greek is *Λ*; the Latin, *L*; the Hebrew, *ל*. In short, two straight lines always form this letter. In Spanish, *ll* are pronounced liquid, like the Italian *gl* before *i*; and it is peculiar to this language, that it begins words with this sound, as,

*llaneros*. In Portuguese, the same sound is expressed by *lh*. The French *ll*, if preceded by *ai, ei, oui*, is liquid (*mouillée*), which, in most parts of France, is pronounced like the Italian *gl* in *egli*; but the Parisian pronunciation, originally a mere provincialism, is almost like our *y* in *you*, as in *travailler, veiller*; and probably this pronunciation will finally prevail, though it is arbitrary, and against the practice of the majority of the people. In Polish, *l* before *t* is sounded by thrusting the tongue between the teeth. The Polish has also the common *l*, and another with a somewhat guttural sound, produced by pressing the tongue against the roof of the mouth, farther back than in the case of the common *l*. For the latter it has a proper sign. In English, *l* is not pronounced at all in some monosyllables, where it intervenes between a vowel and a subsequent consonant, as in *calm, half, balm, chalk, would, could, folks*.

As a numeral, *L* signified, in Hebrew, 30; in Greek, *λ* = 11, and *λ* = 30,000. *L*, in Latin, signifies 50; hence two *Λ*s, put upon each other, forming *ℒ* = 100, which being rounded became *C*, = 100. *Λ*, on Greek coins, means *Locris, Laconia, Lamp-sacus, Lacedæmonia*, &c.; on Roman coins, it means *Lucius, Lepidus, libertas, libra, ludos, libens*, &c. *L*, with a dash over it, meant among the Romans, 50,000. *L*, on French coins, signifies the mint of Bayonne. On Dutch cloths, *L* signifies *Leyden*. On French hats, *L* means *laine* (made of wool only). *L. A. Q. M.* is an abbreviation of *literarum artiumque magister*; *£*, the English abbreviation for *pound* (sterling), from *libra*, the Latin for *pound*. In citations, *l* is often used for *book* (*liber*). See *Abbreviations*.

*LA*, in music; the syllable by which Guido denotes the last sound of each hexachord. If it begins in *C*, it answers to our *A*; if in *G*, to *E*; and if in *F*, to *D*.

LAALAND, or LALAND; an island of Denmark, at the entrance into the Baltic from the Greater Belt, about sixty miles in length, and twelve in its mean breadth, and reckoned the most fertile spot in the Danish dominions. This island produces plenty of

all sorts of grain, particularly very fine wheat, and excellent peas. It is also famous for a kind of red fruit called *manna*. The country lies low, the soil is damp, and the air is very unhealthy. Of all the inhabitants of this island, the clergy are the best provided for, according to their rank. The nobility are numerous here, and many of them have very fine seats, and considerable estates. Naskow is the capital. Population, 38,000; square miles, 459. Laaland, united with Falster, forms a bishopric. Lon.  $10^{\circ} 59'$  to  $11^{\circ} 52'$  E.; lat.  $54^{\circ} 40'$  to  $55^{\circ}$  N.

LAAR, or LAER, PETER VAN, surnamed *il Bamboccio*, a painter, born in 1613, at Laaren, a village near Naarden, in Holland, enjoyed, during sixteen years, the society of the most distinguished artists, viz., Poussin, Claude Gelée (Lorraine), Sandrart, &c., and had considerable influence on the taste of the Italians. In 1673 or 1674, he put an end to his life, probably from hypochondria. He received his surname during his residence at Rome, according to some, on account of his deformity; according to others, from his humorous representations of objects of common life, which he brought into favour. Even in his earliest youth, it was his constant occupation to draw every thing which he met with. His memory served him so admirably, that he could represent objects most strikingly, which he had only seen once, or a long time previous. He was also one of the greatest musicians of his time. He only attempted minor objects, such as fairs, children's games, hunting scenes, landscapes, &c., but his paintings possess great power and animation. The museum of Paris possessed several of his pieces.

LABARRE, JOHN FRANCIS LEFEVRE, CHEVALIER DE, grandson of a lieutenant-general in the French service, was one of the latest victims of religious fanaticism in France. His father having spent his fortune, his aunt, the abbess De Villancourt, took charge of his education, and the youth made much progress in his studies. The command of a company of cavalry had been promised to him, when the following horrible event put a stop to his career. In the year 1765, a wooden crucifix, on the bridge of Abbeville, had been defaced, and the bishop of Amiens, De la Motte d'Orléans, issued a proclamation, demanding a disclosure of the perpetrators of the crime, under penalty of ecclesiastical censures and excommunication. Duval de Saucourt, counselor of the presidial of Abbeville, the private enemy of the abbess De Villancourt, accused the chevalier De Labarre of the crime. Several witnesses were heard. Labarre and Détallonde, a youth of the same age, were ordered to be arrested. The latter fled, and entered the service of Prussia, in which he distinguished himself; but Labarre was apprehended and brought to trial. The indictment charged him with having passed a procession without taking off his hat, of having spoken against the eucharist, and of having sung impious and licentious songs. The tribunal sentenced the young man to have his tongue cut out, his right hand cut off, and to be burned alive. A decree of the parliament of Paris, of June 5, 1766, passed by a small majority, commuted the sentence into decapitation before burning. This decree was executed July 1. Labarre, hardly nineteen years old, was carried to the place of execution in a cart, with the words *impious, blasphemer, sacrilegious, abominable, and execrable*, written on his breast. Voltaire exerted himself as zealously against this infamous act as he had against the execution of Calas. (q. v.) Under the name of M. De Casen, advocate of the royal council, he published a Relation of the Death of the Chevalier De Labarre, which may be found in vol. xxxvi. of his works, ed. Beaumarchais. "A Dominican," he says, "was appointed to attend him as

confessor, a friend of his aunt, the abbess, with whom he had often supped in the convent. This good man wept, and the chevalier comforted him. Dinner was brought to them; but the Dominican was unable to eat. 'Let us take a little food,' said the chevalier to him; 'you will need strength to support the spectacle which I am going to exhibit.' He ascended the scaffold with calmness, without complaints, without anger, and without ostentation, merely saying to the monk who assisted him, 'I did not think that a young nobleman could be put to death for such a trifle.'

LABARUM; the name given to the imperial banner, upon which Constantine, after his conversion, blazoned the monogram of Christ. Eusebius has described it with much particularity. After the vision, in which the luminous cross was exhibited to the emperor, and while he was yet meditating on the meaning of that apparition, a sudden night came on, "at which time," as he said, "the Christ of God appeared to him, when asleep, with that sign which had been shown him in the heaven, and ordered him to get a standard made, in imitation of that which he had seen in the heaven, which he should use as a protection in his engagements with his enemies. As soon as it was day, he arose, and declared the whole secret to his friends. Then he called together the workers in gold and precious stones, in the midst of whom he himself sat, and gave them a description of that standard, and ordered them to express as likeness in gold and precious stones, which standard we ourselves, also, happened some time to have a sight of."

LABAT, JEAN BAPTISTE, a Dominican missionary and traveller, born at Paris 1663, took the vows at the age of nineteen. He afterwards taught mathematics and philosophy at Nancy, where at the same time, he performed the duties of a preacher. In 1683, he returned to Paris, to the Dominican convent, in the street St Honoré. A letter arriving shortly after, from the superior of the Dominicans in the French Antilles, in which this ecclesiastic urged his brethren in Europe to come to his aid, an infectious disease having carried off many of the members of the order, Labat determined to carry into execution the plan he had long entertained of becoming a missionary. As the superiors of the order expected great benefit from his services in France, it was with difficulty that he succeeded in carrying his intention into effect. He embarked, with several brethren of the order, at Rochelle, in 1693, landed at Martinique in 1694, and immediately undertook the care of the parish of Macouba, which he superintended for two years, after which he was sent to Guadaloupe, for the purpose of building a mill, on an estate belonging to the order. His mathematical knowledge recommended him to the governor there, whom he accompanied during a tour through the island, to assist him in selecting the points best adapted for works of defence. On his return to Martinique, Labat found his care assumed by another, and he received the office of *procureur général* of the mission, in which an opportunity was afforded him of displaying the whole extent of his useful activity, at the same time that he served the government by his mathematical knowledge. During several voyages in the service of the mission, he visited all the Antilles, and, on the attack of Guadaloupe, by the English, in 1703, he rendered his countrymen important services as an engineer. In 1705, he was sent to Europe on business of the order, and, landing at Cadix, he embraced the opportunity to survey, geometrically and astronomically, the environs and the whole coast of Andalusia, as far as Gibraltar. He likewise went to Italy, and finally returned to Paris in 1716, where he occupied himself

with the publication of a part of his works, and where he died Jan. 6, 1738. His *Voyage aux Iles de l'Amérique*, of which several editions have appeared, and which has been translated into several languages, contains an account of the natural history, particularly of some of the smaller and less frequented islands; of their productions; the origin, customs, religion, and governments of the inhabitants, as well as the chief political events which occurred during the author's residence there. He also published a Description of the Countries on the Senegal, and between Cape Blanco and Sierra Leone; Travels in Spain and Italy; and a translation of Cavazzi's work on Western Ethiopia. Besides these, Labat edited the *Voyage of the Chevalier Demarchais to Guinea and to Cayenne*, and the *Memoirs of the Chevalier d'Arvieux*, containing his Travels in Palestine, Syria, and Barbary.

LABE, LOUISA, known by the name of *la belle cordière*, was born at Lyons, in 1526 or 1527. Her father had her instructed in music, in several languages, and also in riding and military exercises. This excited in her a desire to enter the army, and, in 1543, she served at the siege of Perpignan, under the assumed name of *captain Loye*. She was commended for her strength and courage. The French being obliged to abandon the siege of Perpignan, Louisa renounced the military service, and devoted herself to literature and poetry. She married a rich rope-maker, Ennemond Perrin, by which means she acquired an opportunity to follow freely her bent for literature. With many agreeable accomplishments, she combined a knowledge of the Greek, Latin, Spanish, and Italian. Her house became the resort of men of learning, rank and wit. She excited the admiration of the poets, but at the same time the envy of the ladies of Lyons. Some contemporary writers have praised her for her virtue, while others have accused her of licentiousness. Several of her poetical effusions, particularly the 18th sonnet, certainly afford cause for suspecting her virtue. She appears to have passed through all the degrees of love: commencing with faithful affection, she became a coquette, and finally an *intrigante*. We may find some excuse for her conduct in the character of the age, when gallantry was not considered dishonourable, and she herself was surrounded by a crowd of amiable but licentious admirers. Her generosity, her taste for learning, and her acquirements, so extraordinary for the times, effaced this stain in the eyes of most of her contemporaries. The tribute which contemporary authors pay her, and the circumstance that the street in Lyons, where her house was situated, was named after her, prove how much she was esteemed. The charm of her conversation, her accomplishment, her talents, the verses which she composed and sung to the lute, contributed to fascinate her numerous and distinguished admirers. Her works are, *Epistle to Clemence de Bourges* (written with great talent); the *Dispute between Love and Folly*, in prose (full of interest and originality); three elegies; twenty-four sonnets, the first of which is in Italian. The first edition of her works appeared in 1555.

LABIALS are letters chiefly pronounced by the lips, as *b, p, f, m*.

LABORATORY (*laboratorium*); a place fitted up for the researches of the chemist. It bears the same relation to the science of chemistry as an observatory does to that of astronomy. Although the simple observation of nature is sufficient to teach us the properties of numerous compounds, and to enable us to develop, in part, those forces which produce chemical changes, still the science of chemistry must ever be remained exceedingly defective in facts, and faulty in theory, but for the light derived from experi-

ment. It is by means of artificial fixtures and processes, that the chemist obtains the elements in a state of freedom, and recombines them so as to produce, in many instances, not only their original compounds, but such as are altogether new. It is no exaggeration to say, that nine tenths of the facts of the science, and a majority of the arts depending upon it, have been derived from the laboratory. The constructions which first received this name consisted of underground apartments, secluded from light and wholesome air of day—a situation it is impossible to account for, except upon the idea that it was copied from the alchemists, who are known to have preferred such places for the purpose of secrecy. The inconveniences attending these situations, from the want of light and facilities for ventilation, as well as from the prevalence of moisture, caused them gradually to be exchanged for apartments above ground; and although, for a time, an unnecessarily gloomy and mysterious aspect was imparted to them, from their being built of stone or brick, and but imperfectly lighted, they have at length come to resemble, in their general appearance, other structures intended for the cultivation of science. Besides laboratories intended for scientific research, there are those which are devoted to articles of chemical manufacture, as the alkaline, earthy, and metallic salts, pigments, &c.; but as these possess considerable diversity in their construction, according to the kinds of manufacture for which they are employed, and cannot well be conceived of without the aid of drawings, we shall omit their description, and confine the present article to a very general account of a laboratory fitted up for the researches of one or two philosophical chemists, in connexion with a theatre, or lecture room, for the public illustration of the science. A building wholly devoted to this purpose, should be but one story in height, in order to facilitate access to the apartments, and to render more easy the bringing in of heavy articles, as wood, water, coals, and carboys, and, at the same time, to allow of openings in the roof for sky-lights and for ventilation. In some laboratories, the theatre and working-room are united in the same apartment; in others, they are separated by a partition. The advantage of the former construction is, that the furnace operations before a class are rendered more easy; but the disadvantages are, that the size of the room renders it an inconvenient place for private researches, especially in the winter, and the seats are continually subjected to the dust and litter of ordinary operations. We shall treat of a laboratory in which these apartments are distinct. The buildings may vary in length from fifty to eighty feet, and in breadth from twenty-five to fifty feet. It should be well pierced with windows laterally, and also with sky-lights and openings in the roof. The lecture-room should occupy two-thirds of the length of the building; and the partition which separates it from the working-room and other apartments, must contain the flues that are requisite for the furnaces of the whole establishment: these may be spread over the wall on both sides, and finally be carried out of the roof in one general chimney. The floor, from eight to twelve feet in advance of this wall, should be paved with stone, or brick; in front of which, and immediately before the seats for the class, a table, with occasional breaks for passages, gasometers, and a pneumatic cistern, should extend quite across the room, from side to side. At the ends of this space, enclosed by the table, cupboards should be erected against the wall, with glass doors, for the reception of the jars of the pneumatic cistern, measures, retorts, flasks, receivers, and the bottles and vials containing the chemicals employed for demonstration. The table should be abundantly provided with drawers of

different sizes, in some places extending down to the floor, for the reception of substances employed in a course of demonstration, and which it is not necessary to keep in vials and bottles, such as the common metals and many earthy and metallic salts; besides for the numerous tools, as knives, files, gimlets, forceps, and other indispensable articles, as corks, valves, or glass plates, stirrers, strings, bladders, tow, matches, sand, tapers, glass, metallic, and earthen tubes, stop-cocks, &c., &c. Two or three portable furnaces, of different sizes and shapes, may have a place near the wall for ordinary furnace operations; and a recess in the wall, centrally placed, and about four feet from the floor (similar in shape to a common fire-place), should be provided, with a strong draught, for those experiments which are attended with dangerous exhalations. The seats may be arranged as is usual in other lecture-rooms. The floor room upon the other side of the partition may be divided, lengthwise of the building, into two apartments, separated by a narrow space-way, one of the rooms having double the dimensions of the other; the larger is the working-room; the smaller, an apartment for receiving delicate articles of apparatus, as balances, electrical machines, air-pump, &c., and which would be liable to injury if exposed to the attacks of the damp and corrosive vapours that are continually floating about in the other rooms. The entry communicates with the theatre by a door; a double door, also, connects the working-room and the lecture-room. The whole floor of the working-room is paved with brick or stone. The first fixture of importance in this room is the general working furnace. Its use is partly domestic, partly chemical; for it is intended to warm and air the place, occasionally to heat water, as well as to supply the means of raising a crucible to ignition, or of affording a high temperature to flasks and evaporating basins, through the agency of a sand-bath. It is built with a table top. The fire-place itself is constructed of brick-work, with iron front and fittings, and the flue, being carried horizontally for three or four feet, is afterwards carried off to, and connected with, the main flue existing in the wall. The fire-place and horizontal flue are covered with a large plate of cast iron, of from two to three feet in width; this is formed, in the middle, over the heated part, into sand-baths; a round, moveable one over the fire itself, and a long, fixed one over the flue. The sand-baths supply every gradation of heat, from dull redness, if required, down to a temperature of 100°, or lower, whilst on each side of them exists a level surface, which answers every purpose of an ordinary table, and supplies extraordinary facilities to experiments going on in the sand-bath or furnace. This furnace may be advantageously placed directly against the wall which separates the working-room from the theatre. A large, flaring, wooden hood should be suspended over the sand-bath, to receive the fumes evolved during the digestions and solutions made upon it, and to conduct them away into the chimney. (For a particular description of this furnace, see Faraday, *On Chemical Manipulations*, p. 90.) Near by may be placed another furnace for heating a large copper boiler, intended to supply the laboratory with hot water; the boiler should also be fitted with a head, worm, and refrigerator, in order to provide an occasional supply of distilled water. The tables should be as extensive as the room will allow, and be so placed as to admit of ready access; hence a large one, placed towards the middle of the room, and in such a situation as to be well lighted, is very useful. It should be made strong, and furnished with drawers, unless it be closed in with doors, so as to form cupboards. To protect it from corrosive fluids, as acids

and alkalies, it should be covered with sheet lead. In a corner, and as much out of the way as possible, a sink of stone, or of strong wood-work lined with lead, must be provided. It must be supplied with water, if possible, from a cistern or aqueduct, since an unlimited supply of water is demanded in a laboratory. A place in its immediate neighbourhood is to be appropriated to the cleansing accompaniments of a sink, such as pails, pans, sponges, brushes, &c. Between the table and the working furnace may be placed the pneumatic cistern, which should be of larger dimensions than that employed in the theatre. If the surface of water be 19 inches by 28, and a well be formed at one end of 14 inches by 10, and 12 inches in depth, so as to leave a continuation of shelf surface, on three sides of the well, of 2½ inches in width, it will be found sufficiently large for almost any purpose. It should have about room sufficient to hold several jars of gas at once. It should be filled with water until it is 1½ inch or 1 inch above the shelf, and should be provided with a stop-cock, by which the water may be drawn off when it has become acidified or dirty. Such a trough is best made of japanned copper, and supported in a wooden frame, so as to stand about 39 inches from the floor; or it may be made of wood, and lined with sheet lead. Unless the establishment is very extensive, one mercurial cistern will answer for both rooms: it may be shaped out of marble or soap-stone, or be made of cast iron, and mounted upon a firm frame, fitted with rollers. Cupboards are very useful; and at least two large ones, with shelves, ought to be provided, in order to preserve chemical preparations, and the neater sort of apparatus, from the dust and dirt which are constantly moving and settling in the laboratory. All parts of the walls within reach should be fitted up with shelves, in a firm manner, to receive bottles and jars; also a tube-rack should be provided, to hold pieces of glass tube, from one to three feet long. A part of the wall should be furnished with long spikes, to hold retort and flask stands, large bent tubes, siphons, coils of wire, iron hoops for holding flasks, &c. Among other indispensable furniture may be enumerated the following articles: one or two large wooden blocks, to serve as bases on which to put heavy mortars; an anvil, or spike with its foot-block; a vice affixed to a side table; hammers; cold chisels; a screw-driver; saws; cutting chisels; gimlets; Brad-awls; half-round, flat, and small three-square files; forceps; a trowel; a soldering iron, with its appendages; a glue pot; nails; screws; spatulas of silver, ivory, steel, and wood; corkscrew; shears; blow-pipes; scratching diamond &c. A number of filtering stands, supports for retorts and flasks, and wooden forms for holding glass evaporating basins, flasks and receivers, should be provided; also a great variety of common kitchen open furnaces. The cellar beneath the working-room should contain the more bulky articles, and such as do not receive injury from a slight degree of moisture, as lute-sand, charcoal, bricks, carbony of antimony, voltaic troughs, &c. We do not go into a description of the common glass apparatus which is essential to a laboratory, as, retorts, adaptors, receivers, manometers, flasks, precipitating glasses, &c., &c., since these articles have come to be well known, under their appropriate names, in every large city where philosophical apparatus is manufactured. Doctor Henry recommends that the painting of that part of the laboratory furniture which is exposed to the action of acids, be done with the sulphate of lead.

*Laboratory*, in military affairs, signifies that place where all sorts of fireworks are prepared, both for actual service and for experiments, viz. quick matches, fuses, port-fire, grape-shot, case-shot, carcasses, and

grenades, cartridges, shells filled, and fuzes fixed, wads, &c., &c.

LABORDE, JEAN JOSEPH DE, a merchant distinguished for activity, enterprise, wealth, and benevolence, was born of an ancient family in Bearn, in 1724, and amassed a large fortune at Bayonne, by commerce with the West Indies and Spain. When, in 1758, the French court wished to obtain a loan of 50,000,000 of livres from the Spanish court, the latter would not close the transaction without Laborde's guarantee. Upon this, Laborde was made court banker, and the first minister, Choiseul, gave him his entire confidence. After the fall of this statesman, Laborde retired from the greatest part of his business. At the breaking out of the American revolution, he alone was able to furnish the government 12,000,000 livres in gold, at Brest, which enabled the expedition under Rochambeau to set sail. At a later period, Laborde employed his fortune in useful and splendid buildings. The palaces of St Onen (since the property of Mons. Ternaux), of St Leu (afterwards belonging to the duke of Orleans), of La Ferté Vidame (belonging to the duke of Penthièvre), and that at Méréville, near Paris, were built by him, as well as the finest houses in the Chaussée d'Antin, a street of Paris, which, in his time, was a large garden, belonging to his hotel. He devoted 24,000 francs, yearly, to the support of the poor. Towards the erection of four large hospitals, at Paris (1788), he contributed 400,000 francs. With this truly royal beneficence he combined the most delicate manners. He never spoke of the good he had done, nor suffered those whom he had served to feel oppressed by the obligation. Satisfied in the possession of the love and esteem of his fellow citizens, he declined external marks of distinction. Louis XVI. raised his estate of Laborde (his family name was *Dort*; his ancestors, who, in 1620, had purchased the small domain Laborde, called themselves *Dort Laborde*) to a marquise; but he made no use of this title. During the period of terror, Laborde lived in retirement on his estate at Méréville, but, like Malesherbes and Lavoisier, who resembled him in nobleness of character, he fell a sacrifice to the fury of the popular leaders. Gendarmes dragged the venerable old man to the tribunal of blood. His whole commune, consisting of 1200, offered to defend their father and benefactor; but he declined it, and exhorted them to keep the peace. These worthy people sent a deputation to the convention, but in vain; the benefactor of thousands fell, at the age of seventy (April 18, 1794), under the guillotine. His crime was being rich. Laborde had four sons. Three of these served in the navy; two accompanied the unfortunate La Peyrouse. They met their death, before the loss of La Peyrouse's vessel, in an act of heroism, which the navigator relates in the account of his voyage, and for which he had a monument erected to their memory, at Port François, on the coast of California. The oldest of these three, after having retired from the navy, was appointed treasurer, and, in 1799, member of the constituent assembly. His reports on the state of the finances were printed by order of the chamber. He died, 1801, a voluntary exile at London.

LABOUR. See *Birth*.

LABOUR, AND LABOURERS. The two great sources of income, in all communities, are labour and capital. The means of production are the land, utensils, stock, and all which constitutes capital, and the labourers who use this capital. In this general division of the means of production, the term *labour* is used in its broadest sense; for the labour of the mind, or that of the artist, which depends more upon skill than muscular exertion, is to be included in the general estimate of the productive

power, if a price or market value is put upon its products in the general estimate. Nor should we, in estimating the general productive capacity, confine ourselves to the species of labour which results in the production of articles of necessity or convenience merely; since, in the products consumed by any community, it is not practicable to draw a distinction between articles of mere utility and those of taste; utility and luxury being combined in a great part of the things used or consumed by a people, whatever may be its stage of civilization and refinement. The land and the greater part of the utensils of production, are estimated, it is true, in a great degree, and, in many instances, wholly, by their mere utility for production. But it is otherwise with respect to the products intended, not merely as the means of producing others, but as ultimate objects of use or consumption. Dwellings, furniture, clothing, food, all combine, in different degrees and proportions, both luxury and utility. The quantity of wool and cotton worn and used by two persons in different ranks of life and of different means of consumption, may be the same, and answer equally well as a protection of the person against the climate; and yet that used by one, owing to the better quality of the material, and the greater labour bestowed in fabricating it, may cost three or ten times as much as that used by the other; and yet something is paid to taste and luxury even by this latter. The abstract utility of any article is of difficult estimation, and, though it is a proper subject of inquiry and speculation, still, in estimating the productive power of labour, in comparison with capital, the more practical rule seems to be, to take the estimate put upon it by the community itself. If, for instance, the labour of a sculptor is, in the estimation of a community, worth that of twenty day-labourers, the distribution of the annual products of the labour and capital of that community will be governed by this rule of comparison, and the sculptor will be able to consume as much in value as the twenty common labourers. Hence the proportion of the income of labour and capital will vary in different communities, according to the different arts or kinds of production encouraged. To take the same examples, though the labour of a sculptor may be equal in value, as estimated by a community to that of twenty labourers,—and the same may be equally true of the painter,—yet the capital or stock required for each of these twenty labourers may be, and, if they are employed in agriculture, will be, greater than is required for either of those artists. The proportion, then, of the value of the whole capital of a community, to that of the whole estimated annual value of the labour of all sorts, performed by its members, will depend upon the kind of arts pursued, so that the proportions will not be uniform in different communities. The estimated annual market value of the labour, will, however, in any community, be greater, in proportion to its capital, than it would at first view appear to be. It has been estimated to be nearly one fifth, exceeding or falling short of that ratio, according to the circumstances and pursuits of a community; that is, supposing the capital to be stationary, the value of the whole capital, including lands, buildings, animals, furniture, utensils, and every vendible thing whatsoever, is consumed and reproduced every five years. It is evident, then, what a rapid change may be made in the wealth of a community, either for the better or the worse, by an impulse or check to its industry, or a general tendency to economy or prodigality in consumption. The arts, and employments, and habits of a people, then, are every thing, in respect to their prosperity; and the actual amount of their present capital is of

less importance, since, if it be too small, that is, if the people are in want of a sufficient stock to employ themselves to the greatest advantage, industry and economy may very soon supply the deficiency. The aggregate annual products of the same labour and capital are greater in one country than another. This is a distinction of great importance, which is overlooked in some economical speculations, or which, at least, has not always its just weight. The fact is, perhaps, too obvious to need proof or illustration. If, for instance, the people of one country have better lands, domestic animals, roads, utensils, or are more skilful and ingenious than those of another, the same amount of manual labour bestowed upon corresponding materials, with corresponding instruments of production, will produce greater results. The wages of labour, and the interest of money, may both, therefore, be higher in one country than in another. This we know to be a fact. In the United States, for instance, the interest of money, and the wages of common labour, are both higher than in European countries. It does not follow, then, that if the condition of the mere labourer is better in one country than in another, that of the capitalist will necessarily be worse. To ascertain the condition of these two classes, possessing the productive capacity and means of a community, we first inquire into the aggregate productiveness of capital and industry, and next into the distribution of the aggregate products between the two classes. And, in examining into the condition of the members of a community, the next inquiry relates to the proportionate share of each industrious class in the whole portion of the aggregate products allotted to industry, as distinguished from that which is allotted to capital. This distribution among the labouring classes themselves, of the products of their labour, will, of course, depend upon the estimation in which the various kinds of labour are held; and its effect on their condition will also depend very materially upon the arrangements, improvements, and facilities possessed by the community, to render their labour effective; for the compensation to labourers, individually, may be small, and yet the expense of the whole class of the community to which they belong, very great. To take a familiar instance, if, from the thinness of the population, or other cause, the receivers and distributors of the articles of production and consumption among the people, that is, the retail dealers, can transact but a small amount of business each, though the earnings of each one may be small, their aggregate compensation must be large. In countries half civilized, and in which the arrangements and facilities for exchanges are rude and imperfect, the usual profits of trade are at an enormous rate per cent.; and yet the wealth of these traders will be very trifling, in comparison with that of the merchants and traders of a more civilized, improved, and populous community, though the per centage of profit of these latter may be much lower. The same distinction will hold good in respect to every other pursuit and employment in a community,—the proportion of the whole products awarded to any one class, may not correspond at all, to the individual advantage or disadvantage of the members of that class, in their pursuits, in comparison with that of those of any other class. The compensation of any one class of a community, in comparison to any other, will evidently depend upon the course taken by the taste and luxury of the community; for we may assume it as a general doctrine, that when the taste and passions of a community lead to a large consumption of the articles produced by any class, or if the services of its members are considered particularly beneficial, those members will be liberally compensated. If, for

instance, as is, or, at least, has been, the fact in some countries, the inhabitants suppose that their future welfare does not depend so much upon their own characters and conduct as upon the prayers and good offices of their spiritual guides, they will deem it impossible to reward these spiritual guides too liberally, seeing they have the salvation of the rest at their disposal. The same principle will hold true in respect to any other class: in proportion as its employment goes along with the tastes and passions of the community, will its members be rewarded for their labours. The effect will not, however, necessarily extend itself to all the members of the class. Suppose, for example, that the taste and vanity of a people appear very much in their apparel and personal ornaments; it will not follow that all cloth makers, tailors, jewellers, hatters, and shoemakers will have the highest wages in the community; but the result will be, that a high price will be paid for excellence of material or superiority of skill, in the manufacture of those articles. The moment, therefore, in which civilization commences,—and some degree of it is coeval with the existence of every society,—excellence in some arts or employments will meet with extraordinary rewards. As arts and civilization advance, the objects of passion and taste will be multiplied, and with them the kinds and varieties of excellence of materials or skill, which will be esteemed of extraordinary value. The effect necessarily is to produce a comparative depression in the value of all ordinary products and unskilful labour. Accordingly, the ordinary labourers, as in the arts, become by degrees a distinct class. In a refined community, abounding in arts, this class necessarily becomes numerous, and the condition of its members is a subject of solicitude to the philanthropist, and of interest to the economist and statesman. The security and welfare of the whole community, will depend very materially upon the character and condition of this part of the population. The greater the distance between this class and the rest, the more effectually they are set off from the others, the more unnatural and distorted will be the state of society, and the more frequent will be scenes of disorder, distress, and vice. It is one of the first and most important maxims of policy and of economy then, to sustain the members of this class, not by giving them the control and management of affairs, for which, of course, they are not the best fitted,—but by using all possible means, whether by legislation or social influence, to give them education, good habits, and good morals; to inspire and maintain in them a respect for themselves, and secure to them the respect of others.

**LABOUR-SAVING MACHINES.** *Montesquieu* somewhere regrets the introduction of the use of water-mills for grinding corn, instead of the hand-mills formerly in use, as it threw a great many labourers out of employment, besides diverting the water from the purposes of irrigation. Upon the principle of throwing labourers out of employment, our hand-loom weavers were opposed to the use of power looms. It is not remarkable that labourers themselves, who, for a time, feel the inconvenience of the introduction of any improvement, should oppose its introduction; but it is singular that any man of enlarged and philosophical views should fall into such a notion. Nobody certainly would think it a misfortune to a community, that, in consequence of some improvement in agriculture, the same labour would produce a greater quantity of grain; on the contrary, every one consents to the praise bestowed by Johnson, upon the man who makes two blades of grass grow where only one grew before. And an improvement in machinery, whereby the same labour

will produce twice the quantity of cloth, is precisely the same in its general effects upon the condition of the community, as an improvement in agriculture. But in a case of improvement in machinery, the effect is more apparent and more sudden, as it will spread rapidly, and, accordingly, the inconvenience to the labourers is, in fact, greater, though it can last only for a time. However, the circumstance that its effect in discharging labourers is only temporary, though it shows that the inconvenience to the community is very limited, while its advantages are permanent, yet affords no great consolation to the labourers themselves, if the population is dense, and employment difficult to be obtained, since, while this temporary effect is passing off, they may starve. To avoid producing distress, and consequent disorder, labour-saving machinery, therefore, should be introduced gradually among a community of labourers, like those of Britain, to whom it is ordinarily difficult to find full employment, and who, if unemployed, are immediately reduced to distress. Hitherto no inconvenience has been experienced in North America in consequence of the introduction of improvements in machinery, since it is, as yet, the more general habit of all classes to save something, so that very few are reduced to immediate distress, though thrown out of employment; and there is usually less difficulty in obtaining full employment for the industrious classes than in most other countries; and, accordingly, all classes are in favour of improvements and inventions whereby labour may be saved, or its products augmented.

LABOURING of a ship implies pitching or rolling heavily in a turbulent sea—an effect by which the masts and hull are greatly endangered; because, by the rolling motion, the masts strain upon their shrouds with an effort which increases as the sine of their obliquity; and the continual agitation of the vessel often loosens her joints, and makes her extremely leaky.

LABRADOR; an extensive country of North America, lying between Hudson's bay, the Atlantic ocean, and Canada, and extending from the fiftieth to the sixtieth degree of north latitude, or nearly 700 miles in length, from north to south. It is about 500 miles in breadth, but has never been fully explored, and is little known, the severity of the climate and the barrenness of the region confining the visits of foreigners principally to the coasts. These are bordered by innumerable islands, so close together as to bear the appearance of main land, broken by inlets: this has given rise to much confusion in the charts. The summer is short, but extremely hot, and the winters are very rigorous. Great numbers of fish, of various kinds, particularly cod and salmon, are found on the shores, and in the small rivers. The islets are covered with flocks of sea-fowl, particularly eider ducks. Bears, wolves, foxes, hares, martens, &c., are numerous. The population is small. The natives of the coast are Esquimaux. The tribes of the interior are little known. Labrador belongs to Great Britain, and is annexed to the government of Newfoundland. The Labrador fishery, in 1829, was calculated to employ 2108 vessels, and 4,100 seamen; 600 of the vessels, manned with 110 men, and producing 678,000 cwt. of fish, and 730 hhds. of oil, were British; and 1500 vessels, manned with 15,000 men, and producing 1,100,000 wt. of fish, and 11,000 hhds. of oil, were from the United States. See *Fisheries*.

LABRADORITE, or LABRADOR FELDSPAR. his mineral scarcely differs from feldspar (q. v.) in its properties of its crystalline structure, except in giving one of its cleavages somewhat less distinct hardness, also, it is nearly identical with that

species; but its specific gravity is somewhat higher, being 2.75. The remarkable opalescent and iridescent tints which it exhibits, constitute its most striking character. Its ordinary colour is a dark gray. Its reflections, which, for variety and intenseness of colour, vie with those of the opal, are visible only upon two opposite sides of any crystal or mass. Blue and green colours are the most common; but occasionally these are intermingled with rich flame-coloured tints. It is sawed into slabs by the lapidaries, and employed in inlaid work. The finest pieces are very highly esteemed. A square table, composed of two pieces of this stone, and whose dimensions were thirteen inches by twenty, and eight lines in thickness, was sold, in Paris, for 1800 francs. The Labradorite is composed of 54.6 silica, 29.0 alumine, 11.8 magnesia, and 4.6 soda. It was first distinguished by the reverend B. Latrobe, among a number of specimens sent to him from Labrador by the Moravian missionaries. It occurs, not only in pebbles on the shore, but in spots in the rocks about Nain, and particularly near a lagoon about fifty or sixty miles inland. Its colours, darting through the limpid crystal of the lake, and flashing from the cliffs, more especially when moistened by a shower of rain, changing continually with every alteration in the position of the spectator, are described as almost realizing a scene in fairy land. Labrador feldspar is also found upon the borders of the gulf of Finland, and at Fredericksværn, in Norway, and at some other places.

LABYRINTH, with the ancients; a building containing such a number of chambers and galleries, one running into the other, as to make it very difficult to find the way through it. The Egyptian labyrinth, the most famous of all, was situated in Central Egypt, above lake Mœris, not far from Crocodilopolis, in the country now called *Fajoom*. According to some writers, it was built by the Dodecarchs (650 B. C.); according to others, by Psammethichus; according to others, by Ismandes, who is also said to have been buried there. In all probability, it was a sepulchre. The building, half above and half below the ground, was one of the finest in the world, and is reported to have contained 3000 rooms, the arrangement of which seems to have been symbolic of the zodiac and solar system. All these rooms were encircled by a common wall and by columns; but the passages were so intricate, that no stranger could find the way without a guide. It is said, that, in the lower rooms, the coffins of the builders of this immense fabric, and of the sacred crocodiles, were deposited, and that the upper rooms excelled, in splendour and art, all human works. At present, only 150 rooms are reported to be accessible: the others are dark, and choked with rubbish. Respecting the interior construction and the destination of the labyrinth of Crete, we know still less. The ancient writers consider this subterranean cavern to have been built by Dædalus, in imitation of that of Egypt, but on a smaller scale, by order of Minos, who confined there the Minotaur. According to others, it was a temple of the latter. The labyrinth at Clusium was erected by king Porsenna, probably for his own sepulchre. It was a square building of stone, fifty feet in height, and thirty on each side. At each corner stood a pyramid, and also one in the centre, each 150 feet high, and at the base, seventy-five feet wide. These edifices were not built for the purpose of making people lose their way; this was merely an accidental peculiarity, on account of which every confused mass of things, difficult to be disentangled, has been called a *labyrinth*. The same name is also given to a part of the ear (q. v.).

LAC, LAK, LAAK, and LAK'HI, are different

ways of spelling the vulgar derivatives from the Sanscrit words *laksha* and *laksha*, i. e. one hundred thousand; a name given by the Hindoos to the *coccus lacca* and *gum-lac*, for which they have six different terms; "but they generally call it *laksha*," says Sir William Jones, (*As. Res.* ii. 364), "from the multitude of small insects which, as they believe, discharge it from their stomachs, and at length destroy the tree on which they form their colonies." The gum-lac is probably discharged by the *coccus*, as a defence for its eggs, which are deposited on the bihar tree. Four kinds are known—stick-lac, seed-lac, lump-lac, and shell-lac. The first is the gum before its separation from the twigs, which it incrusts; and the best is of a red purplish colour: the second is the gum in a granulated form, stripped from the twigs, and perhaps boiled, by which a portion of the colour is lost: the third is the seed-lac, melted into cakes; and the fourth, the common form in which it is known in Europe, is the purified gum. The best is amber-coloured and transparent. In the East, it is much used for trinkets. It is the basis of sealing-wax. It forms varnishes, furnishes a brilliant red dye, and, mixed with thrice its weight of fine sand, is made into polishing stones. (See *Coccus*.) *Lac*, in its original meaning, is applied to the computation of money in the East Indies. Thus a *lak* of rupees is 100,000, which, supposing them to be *sicca*, or standard, equal £12,500.

LACAILLE. See *Caille*.

LACCADIVE ISLANDS; a group of small islands in the Indian sea; the nearest is about 120 miles from the coast of Malabar; lon.  $71^{\circ} 15'$  to  $73^{\circ} 30'$  E.; lat.  $10^{\circ}$  to  $12^{\circ} 40'$  N. These islands are supposed to be what Ptolemy called *Insula Numero XIX*; but, in fact, they are thirty-two, all of them small, and covered with trees. They are rocky on their sides, mostly as if laid on a bottom of sand, attended with reefs, and the channels between them very deep. They are commonly visited by British ships, in their way from India to the Persian gulf or Red sea. The principal traffic of the inhabitants is in the produce of the cocoa palm, such as the oil, the cables and cordage prepared from this plant; and in fish, which is dried and sent to the continent of India, from whence they get rice, &c., in return. They also trade to Mascat, in large boats, and bring back, in return for their commodities, dates and coffee. Ambergis is often found floating off these islands. The inhabitants are mostly Mohammedans, called *Moplays*.

LACE; a delicate kind of net-work, formed of silk flax or cotton thread, used for the ornamenting of female dresses. Its meshes are of a hexagonal or six sided figure, and formed by twisting together the threads of the substances just mentioned. Thicker threads are also interwoven to form the figures or patterns, according to some regular design, and these (called technically the *gimp*), form the ornaments of the lace. There are several different kinds of lace, which are more or less esteemed according to the fashion of the day, and valued in proportion to their rarity more than from any real difference in their quality and appearance. That of England is generally called Buckinghamshire, Bedfordshire, or Devonshire, according to the several counties in which it is made. It is also called pillow or bobbin lace, from being woven upon a pillow or cushion by means of bobbins. It consists of hexagonal meshes, four of the sides of each mesh being formed by twisting two threads round each other, and the other two sides by the simple crossing of two threads over each other. This is the kind manufactured at Lisle in France, and Nottingham in England. Another kind is made at Honiton in Devonshire, and called

Honiton or Devon lace. It is of the same kind as that made at Brussels. Two sides of each mesh of this are plaited of four threads, and the four other sides by threads twisted together. The plaiting renders it much more durable than the twist lace, and it therefore bears a much higher price. There is also a third sort of lace manufactured at Valenciennes, but which is not made in England at all. In this all the six sides of the mesh are plaited, but two of the sides of each mesh are so small that they appear like lozenges. At Nottingham imitations of lace are produced by machines, called *point net* and *warp net*; from the names of the machines in which they are made. They are both a species of chain work, and the machines are varieties of the stocking frame. The warp frame makes a very close imitation of the Brussels lace, but has very little durability. The Buckinghamshire lace is woven on a pillow or cushion, which the woman or child who makes the lace, places on her knees. The threads are wound upon bobbins, or small round pieces of wood, each about the size of a pencil, having round their upper ends a deep groove, so formed as to receive the bobbin to a thin neck, and on which the thread is wound; a separate bobbin being used for each thread. To form the meshes pins are stuck into the cushion, and the threads are woven or twisted round the pins, a piece of parchment being first fixed down upon the cushion, pierced previously through with small pin holes in regular order to show the proper places for the pins; and on this parchment the design for the gimp is also traced, so that it may be interwoven with the finer threads, and form the figures. The work is begun at the upper part of the cushion, by tying the threads together in pairs; and each pair is then attached to a pin, which is stuck through the parchment into the cushion; the round form of which allows the threads to hang down and remain steadily on whichever side the bobbins are placed. The woman taking one pair in each hand with her finger and thumb, twists the bobbins round each other three times, the effect of which is to twist the threads of each pair together, and this is done by both hands at the same instant of time. The twisting, which forms the two sides of the mesh being completed, the adjacent bobbins of each pair are interchanged in order to cross the threads of those bobbins over each other, and then from the bottom of the neck. Thus, for instance, supposing the bobbins numbered one, two, three, and four. No. 1 is twisted round 2, and 3 is twisted round 4. Then in order to cross, 2 and 3 are interchanged, so that 1 and 3 come together, and 2 and 4; and the next time that the twisting operation is performed, these pairs of threads will be combined together. When a mesh, or half mesh is made, it must be secured by putting a pin into the cushion; and in order to draw the twist work close, the pin is introduced between the recently crossed threads, and carried up towards the top of the pillow, so as to drive the twists and cross before it, and draw the twists into a closer compass. The pin is then inserted into its proper hole in the parchment, and will prevent the threads from returning. These four bobbins are now laid apart for the present on one side of the cushion, when two other pairs are brought forward in front, and twisted and crossed in the same manner; and in this way the work proceeds till a row of meshes is formed all across the breadth of the intended piece of lace, and then the same bobbins are worked over again to make another row. In general the number of bobbins is equal to 20 or 60 to each inch of breadth. These operations are performed with the greatest dexterity, but the work goes on very slowly, so many meshes being required

for a very small piece of lace. Thus, taking the threads at 50 per inch, if the lace be one inch wide, it will have 25 meshes in its breadth, or 625 meshes in each square inch of length, or 22,000 meshes in a yard; and yet the price given for a yard of lace of this description is seldom more than one shilling and sixpence.

The point net frame was invented by Mr J. Morris of Nottingham in 1764, and forms lace out of one continued thread, which is laid across a row of needles, and by the actions of jacks and sinkers, as in a stocking frame, is formed into loops; but before finishing the operation of the chain work, the row of points is plied between the needles of the frames and the points being only half the number of the needles, they take up every other loop, and by a particular motion cast them over the neighbouring needles, so as to gather the two loops together into pairs, and leave intervals between each pair, consequently when the usual operations of the stocking frame are resumed, the stitches will be found to be worked two into one.

The objection to this imitation is that it becomes loose and irregular after being worked, and if the thread breaks, the work will unravel like a stocking. Lace, made by another machine called a warp frame, is more durable, and is capable of being made of several different patterns.

The Nottingham lace, has been superseded by that made on a machine invented by Mr John Heathcoat in 1809, which can make lace of any required breadth. In this, the warp threads are wound upon a roller, at the bottom of the machine, and carried up to a work beam, or roller, situated at the top of the machine. There are also diagonal threads, wound upon small detached bobbins, and regularly interspersed between the warp threads. The bobbins are small flat wheels, about the size and thickness of a shilling, with a deep groove upon their edges, upon which the thread is wound. These being fitted into a small carriage or frame, which will turn round freely when the thread is drawn off, but guarded by a slight spring, so as to give some resistance and draw the thread tight. The bobbins and their carriages are so thin, that when placed side by side in rows, they merely occupy the same breadth as the lace. The longitudinal threads are stretched in a perpendicular direction, from the thread to the lace-roller, forming a row of parallel threads, arranged equally distant from each other; and to guide them, each thread is conducted through a small eye, in a wire resembling a needle. Two rows of such guides are fixed on two bars, placed horizontally, each capable of a small side movement, so as to carry these threads along with them. On each side of these, is a horizontal or *comb-bar*, having its upper surface cut into grooves, to receive the bobbin carriages. These run along the upper side, and across the length of the bar. Behind the row of threads is another comb-bar, precisely similar to that in front. The bobbin carriages can pass freely to and fro between these two comb-bars, but there is only such space between them, as to allow them to enter the grooves of one while still playing in those of the other. By means of two thin bars or rollers, the bobbin carriages are repeatedly moved backwards and forwards, and transferred alternately from the front to the back comb-bar, and in so doing, pass between the perpendicular threads—at each transfer, the bar sustaining the guides is moved sideways through a distance equal to the interval between the grooves of the combs, by which movement the perpendicular threads, come to be placed alternately on each side of the moving bobbin carriages, so that a twist is made every time, and the sides of the meshes are thus formed.

The operations of drawing the twist close, and giving the necessary form to the meshes, is done by means of a row of sharp pin points, which are suspended in a frame, so as to be brought down, and introduced between the threads beneath the crossings, and being moved upwards, the points carry the twists and crossings before them, draw them close, and give the requisite form. There are two rows of points, one used as above, and the other to relieve them, and hold fast the newly formed meshes, whilst the other respects the action.

This machine is most ingenious, and works with great rapidity. The operator is seated in its front, and employs both hands and feet in imparting the required motions. The machines are of various widths, from one to two and a-half yards, and the bobbins are from ten to twelve per inch in each row, or (being double), twenty to twenty-four per inch, so that if the machine be two yards wide, their number will be from 1440 to 1728, but all these are passed between the perpendicular threads in an instant, and it is rarely that any confusion takes place.

Most of the Nottingham machines at present, are upon the principle of Mr Heathcoat's, and work by license under his patent. His invention has been lately carried over to France, and manufactories are established both at Calais and Douay.

*Lace made by Caterpillars*; a most extraordinary and ingenious species of manufacture, which has been contrived by an officer of engineers residing in the city of Munich. It consists of lace and veils, with open patterns in them, made entirely by caterpillars. The following is the mode of proceeding adopted:—Having made a paste of the leaves of the plant, on which the species of caterpillar he employs feeds, he spreads it thinly over a stone, or rather flat substance, of the required size. He then, with a camel-hair pencil, dipped in olive-oil, draws the pattern he wishes the insects to leave open. This stone is then placed in an inclined position; and a considerable number of the caterpillars are placed at the bottom. A peculiar species is chosen, which spins a strong web; and the animals commence at the bottom, eating and spinning their way up to the top, carefully avoiding every part touched by the oil, but devouring every other part of the paste. The extreme lightness of these veils, combined with some strength, is truly surprising. One of them measuring twenty-six and a-half inches by seventeen inches, weighed only 1.51 grains—a degree of lightness which will appear more strongly by contrast with other fabrics. One square yard of the substance of which these veils are made, weighs four grains and one third; whilst one square yard of silk gauze weighs one hundred and thirty-seven grains, and one square yard of the finest patent net weighs two hundred and sixty-two grains and a half.

LACEDÆMON. See *Sparta*.

LACEPEDE, BERNARD GERMAIN ETIENNE, count Delaville sur Ilon de, naturalist, peer of France, born at Agen, 1756, was from his youth, passionately attached to natural history and music: he consequently abandoned the military profession, for which he was destined, and devoted himself to the study of natural history. His teachers and friends, Buffon and Daubenton, procured him the important situation of keeper of the collections belonging to the department of natural history in the *jardin des plantes*. At the breaking out of the revolution, he was elected member of the legislative assembly, and belonged to the moderate party. To withdraw from the storms of the period of terrorism, he resigned his situation, and retired to his country seat, Lieuville. He again made his appearance under the directory, and was appointed one of the first members of the institution. Napoleon

made Lacépède a member of the conservative senate, and conferred on him the dignity of grand chancellor of the legion of honour. Lacépède became one of the most zealous adherents of the emperor, and during the ten years of the imperial reign, few public celebrations occurred at which he did not appear as an orator. His benevolence and his inattention to his own affairs involved him in debt. Napoleon, therefore, gave him a salary of 40,000 francs. After the first restoration, Lacépède lost his situation of grand chancellor of the legion of honour, but was raised to the peerage by the king. During the hundred days, the emperor appointed him grand master of the university; but he declined this office, and devoted himself solely to the sciences. In 1817, he published a new edition of Buffon's works, and announced, at the same time, that, at the desire of his deceased friend Lagrange, he intended to publish his *Theory on the Formation of Comets*. He likewise published a continuation of the work on the Cetacea, commenced by his great predecessors. His *History of Fishes* (5 volumes, 4to.), is considered his principal work. The complete collection of his works, in which are included two small novels, which appeared anonymously, and the opera *Omphale*, is voluminous. Lacépède could adorn the driest subjects with the graces of a brilliant style. He died Oct. 6, 1825, at his country-seat Epinay, near St Denis, of the small-pox. Villeneuve wrote his *Eloge Historique* (Paris, 1826). Of Lacépède's very defective *Histoire Civile et Militaire de l'Europe* (from the end of the fifth, till the middle of the eighteenth century), in eighteen volumes, the two first volumes appeared after his death Paris, 1826.

LACHAISE, FRANÇOIS D'AIX DE, confessor of Louis XIV., member of the congregation of Jesuits, was born in the *château d'Aix*, in August, 1624. The family D'Aix de Lachaise was one of the most respectable in France, and a grand uncle of François de Lachaise, father Cotton, had been confessor of Henry IV. In the Jesuit college at Rohan, which had been founded by one of his ancestors, Lachaise commenced his course of studies, and finished it at Lyons. He was the provincial of his order, when Louis, on the death of his former confessor, father Ferrier, appointed Lachaise his successor. This appointment occasioned surprise, because, on the one hand, the disputes between the parties of Jansenists, Molinists, &c., divided the court of Louis XIV., already infected, by the example of the king, with a sickly kind of devotion, as also the capital, which fluctuated, in imitation of the court, between licentiousness and bigotry; and, on the other hand, no Jesuit, since father Cotton, had been chosen to this important situation. The new confessor was soon involved in a web of court intrigues. Mme. de Montespan and Mme. de Maintenon, the Jansenists and Jesuits, stood opposed to each other, and Louis, moved by sensuality and superstition, wavered like a reed between these parties. Nevertheless, Lachaise maintained his ground, although he was equally obnoxious to Mme. de Montespan and Mme. de Maintenon, who frequently expressed their dislike to him in bitter sarcasms. On every occasion—at the famous declaration of the French clergy respecting the liberties of the Gallican church, at the revocation of the edict of Nantes, on occasion of the disputes of the Quietists, at the marriage of Mme. de Maintenon with the king (1686), and similar important events of the time—father Lachaise, in consequence of his office, was more or less forced to play a part; and, although he reflected well on every step he took, he constantly received the severest reproaches from both parties. The most intelligent men, however, never judged unfavourably of his pri-

vate character and his conduct; and St Simon, who was no friend to the Jesuits, as well as Voltaire, in his account of the age of Louis XIV., De Bon, Spon, and others, acknowledge, that the confessor of the vainest monarch, and the mediator between the most exasperated parties, knew how to conduct himself, under all circumstances, with address, comeliness, and sagacity, and that, although a Jesuit, he never allowed himself to be drawn into violent measures against his opponents. That Louis formally married Mme. de Maintenon, Voltaire attributes principally to the counsels of Lachaise; but that this marriage remained secret, and was not publicly acknowledged, according to the desire of that ambitious woman, may likewise be attributed to Lachaise, who, on this account, had constantly to endure her hatred. Lachaise, maintaining his ground in the favour of his monarch till his end, and acting as his counsellor, even when age and weakness had almost converted him into a living skeleton, and weakened his faculties, died January, 1709, at the age of eighty-five. He left philosophical, theological, and archaeological works. His taste for the study of numismatics, and the great share which he had in the improvement of this branch of science in France, are well known. Louis XIV. had a country-house built for him at the end of the present *Boulevard des Capucines*, which, at that time, owing to its situation on a hill, received the name of *Mount-Louis*. Its extensive garden now forms the cemetery of *Port Lachaise*, the largest in Paris. (See *Cemetery*.) Many splendid monuments now adorn the place, where, formerly, the courtiers of Louis XIV. used to meet, to pay their respects to the confessor of their absolute master. The situation of the burying-place, on the declivity of a hill, affords one of the most delightful views of a principal part of the city and its suburbs. At the approach of the allies, in 1814, this burial-place was fortified, and defended by the students of the polytechnical and veterinary school. The Russians, in storming it, did a great injury: the shaded walks, particularly, suffered by the bivouac of the troops, but have since been repaired. A short time previous to the second taking of Paris (1815), viz. from June 24 till July 8, no burials took place in the cemetery of *Port Lachaise*, on account of the troops which surrounded the capital. During this time, the dead were buried in the cemetery of Ste. Marguerite, situated in the town, which had been long out of use.

LACHRYMÆ CHRISTI (*Latin*, tears of Christ; a superior kind of Italian wine, so called, it is said, because it drops like tears from the press, before the grapes are subjected to any pressure except their own weight. It is dark-red, and the grape grows at the foot, and to a certain height, on the sides, of mount Vesuvius. On several of the Greek islands, also, a kind of wine is produced in the same way.

LACHRYMATORIES (i. e. *tear-bottles*; from *lachryma*, *Latin*, a *tear*); small glass or earthen vessels found in tombs, so called, because they were supposed to have been used by the ancient Romans to collect the tears of the friends of the deceased. Some of them contain the impression of one or of two eyes. They are now considered to have been used for containing aromatic liquors, to be passed upon the funeral pile.

LACLOS, PIERRE-FRANÇOIS CHODERLOS DE, author of the famous romance *Les Liaisons dangereuses*, which first appeared in 1782, was born at Amboise, in 1741, and, before the revolution, was a French officer of artillery, and secretary to the duke of Orleans. Laclos was considered, when he was young, as one of the most talented and agreeable, and, in a moral point of view, as one of the most

dangerous men. His enemies have maintained that he has drawn his own character in that of the viscount de Valmont in his romance. Others celebrate the simplicity, honesty, and good nature of his character, at least in the latter part of his life. He was one of the leaders of the Orleans faction, as it was called. Being implicated in the affair of the 5th and 6th of October, he followed the duke of Orleans to London. After the return of the king from Varennes, Laclos endeavoured, by means of the Jacobin club, to effect the foundation of a republic, as he conceived that this step would lead eventually to the elevation of the house of Orleans to the French throne. At the breaking out of the war, Laclos was transferred as an assistant to the old Luckner, and, after the fall of the house of Orleans, he disappeared from the stage. It is difficult to explain how Robespierre came to spare a man who was one of the firmest adherents of this proscribed house; and thus the report originated, that Laclos prepared the speeches of the tribune of the people. After the 9th Thermidor, Laclos returned to the military profession, and was advanced to the office of inspector-general of artillery. He died at Tarentum, in 1803.

LACONIA. See *Sparta*.

LACRETELLE; two brothers well known as authors, but entirely opposed to each other in principles.

1. *Pierre Louis Lacretelle*, the elder (commonly called *Lacretelle aîné*), was born in 1751, at Metz, where his father was an advocate, and died Sept. 5, 1824, at Paris. Animated, by the masterly works of the advocate-general Servan, to the study of the law, ethics, and literature, he went, in 1778, to Paris, where he became parliamentary advocate, and by his writings—*Eloge de Montausier* (which obtained the second prize in 1781), *Mémoires du Comte de Saurais* (a work new and unique in its kind), and the *Discours sur le préjugé des Peines infamantes* (which received the prize of the academy)—rendered himself worthy of a place in the institute, where he succeeded La Harpe, with whom he was concerned in editing the *Mercur*—an occupation which he undertook anew, in 1817, under very different circumstances, in conjunction with Jouy, Jay, B. Constant and others. Lacretelle embraced the principles of the revolution with the ardour of a noble mind, but without concurring in its excesses. In the legislative assembly, in 1792, he was one of the leaders of the constitutional party, in opposition to the Girondists, who were in favour of republicanism. After the 10th of August, Lacretelle devoted his attention wholly to literature. We find him again in public life in 1801, when he was a member of the legislative body of Napoleon. Here he retained his independence in the midst of political revolutions. When the government of Napoleon destroyed his hopes of the establishment of a liberty founded on the laws, he again retired. His poverty, which he neither complained of nor regretted, was honourable to him. The aristocratical reaction, which took place in France, after the second restoration, and was particularly memorable in the chamber of 1815 (see *Chambre Introuvable*), threw him into the opposition, which the liberal party at that time began to form, and in support of which they had undertaken the direction of the *Mercur de France*. But this journal, which appeared on fixed days, becoming subject, in consequence of a new law, to the inspection of the censor of the press, was given up, and the *Minerve Française*, which appeared irregularly, took its place. Lacretelle, in conjunction with Aignan, had the direction of this literary and political journal. The *Minerve Française* obtained so decided an influence upon public opinion, that this was also subjected, by a new ordinance, to

the censorship, after eight volumes had been published, upon which it was immediately discontinued. Lacretelle, who was now a bookseller, hazarded a continuation of it in the form of small pamphlets; but he was subjected to a prosecution, in which he defended himself with great energy and ability. He was condemned, however, to imprisonment; but Louis XVIII. remitted the sentence on account of his age and infirmities, and the general esteem in which he was held. From that time, Lacretelle employed himself upon a collection of his works, which appeared at Paris, in 1823, in four parts. He was the author of many logical, metaphysical, and ethical articles in the *Encyclopedie methodique*. Many of his scattered essays and treatises appeared in 1802, under the title of *Œuvres diverses*, in five volumes, to which, in 1817, he subjoined *Fragments politiques et littéraires*, and, in 1822, *Œuvres, and Portraits et Tableaux* (among them those of Mirabeau, Bonaparte, and Lafayette), in two volumes. His theatrical romance *Malherbe, ou le Fils naturel* (D'Alembert), is an excellent dramatic poem. His *Soirées avec Guillaume Lamoignon de Malesherbes*, and his *Etudes sur la Révolution Française*, are also highly esteemed. Both have been published since his death.

2. *Charles Lacretelle*, the younger brother of the preceding, went, when very young, to Paris, at the breaking out of the revolution. He soon attracted attention by his logical acuteness, and the editorial department of the *Journal des Débats*, which was established at that time, was committed to him in connexion with another individual by the name of H. Ducos. His second literary production was his *Précis de la Révolution*, which was a continuation of the work of Rabaud St Etienne. On the occasion of the opposition of the Parisian sections to the decree of the national convention retaining two-thirds of their number in the new legislature, Charles Lacretelle composed, in the name of the sections, the caustic addresses to the convention, as well as to the electoral assemblies of France; but, on the 13th Vendémiaire, Bonaparte put an end to these commotions. Being, however, attached to the then existing opposition, and using his influence in its favour, he was, on the 18th Fructidor, arrested, and retained prisoner for two years. After the 18th Brumaire, however, Napoleon employed his talents in various occupations. In 1813, he received Esme-nard's place in the national institute, and, in 1816, the presidency of the French academy, or the third class of the institute. The historical lectures, which, as professor of history, he delivered before the university of Paris, were among the most frequented in that city. As an historical writer he has a peculiarly brilliant diction, although his ideas want force and profundity. His *Histoire de France pendant les Guerres de Religion* is more highly esteemed than his *Histoire de France pendant le dix-huitième Siècle* (14 volumes, 1826). Lacretelle has now renounced his former philosophical views. In his *L'Histoire de l'Assemblée constituante*, he takes part entirely with the ultras and obscurants. During twenty-six years, he was censor of the department of the drama. He has been termed the chief support of the *Société des bonnes Lettres*, so called. He was likewise honoured with the dignity of nobility by Louis XVIII. In 1827, the ministry deprived him of his censor's office, because he favoured, in the academy, the petition to the king against the laws respecting the censorship of the press. In 1829 appeared his *Histoire de France depuis la Restauration*.

LACTANTIUS, LUCIUS CÆLIUS FIRMIANUS, a celebrated father of the Latin church, distinguished as an orator and author, is commonly supposed to have been an African. He lived for a long time at

Nicomedia, as a teacher of rhetoric, until Constantine the Great committed to his care the education of his eldest son, Crispus. He died about 325. His writings (published by Sparke, at Oxford, 1684; by Bunemann, at Leipsic, 1739; by Dufresnoy, at Paris, 1748, 2 volumes, 4to; and by Oberthur, at Wurzburg, in 1783, 2 volumes) are characterised by a clear and agreeable style, and he is, on account of his pure and eloquent language, frequently called the *Christian Cicero*. His seven books, *Institutiones divinae*, are particularly celebrated, and worthy of notice.

**LADIES' SLIPPER** (*Cypripedium*); a beautiful genus of orchideous plants, conspicuous for its large, inflated flowers. The roots are perennial; the stems simple, bearing entire sheathing leaves; and the flowers are solitary or few in number. The species are confined to the northern regions of the globe: six inhabit the Alleghany mountains, Canada, and the northern parts of the United States; and five are found in Siberia, and the northern and mountainous parts of Europe.

**LADOGA, or LADOZSKOI**; a lake in Russia, between the Baltic and the lake Onega, surrounded by the governments of Petersburg, Viborg, and Olo-nets. The south-west extremity lies thirty miles east of Petersburg. It is 140 miles long, and 75 broad, containing 6200 square miles, and is the largest lake in Europe. It contains an abundance of fish, particularly salmon. The shores are flat, but the navigation dangerous on account of quick-sands.

**LADRONES**; a cluster of islands in the Northern Pacific ocean, discovered by Magellan. Their number is stated by some authorities as fourteen, by others as sixteen. They occupy a space of 450 miles; lon. 145° to 148° E.; lat. 13° to 21° N. Magellan called them *Islas de Ladrones* (islands of thieves), because the natives stole every thing made of iron which they could find. Towards the end of the seventeenth century, they received the name of *Mariana*, or *Marianne* islands, from the queen of Spain, Marianne of Austria, the mother of Charles II., at whose expense missionaries were sent over thither, to propagate the Christian faith. In almost all books of history and voyages, as well as in maps, we find them styled the *Ladrones*; notwithstanding which, the above-mentioned name has gradually gained ground. These islands lie in the torrid zone; and yet so much is the heat of the sun tempered by the air, and by breezes of the sea, that the climate is generally serene, salubrious, and pleasant: in some seasons of the year only they are liable to hurricanes, which, though they do sometimes a great deal of mischief, yet clear and refresh the air in such a manner that, before they were visited by the Europeans, the people commonly lived to a great age. The inhabitants are tall, robust, active, and ingenious. They wear little clothing. Both sexes stain their teeth black, and paint their bodies red. Their religion is an ignorant superstition. That most extraordinary and useful plant, the bread-fruit tree, was first discovered here.

**LADY-BIRD**; a pretty species of beetle, belonging to the extensive genus *coccinella*, having the elytra red, bordering on yellow, and adorned with two black spots, one on the middle of each. It appears, however, that almost all the small and spotted beetles of this genus are indiscriminately known under the name of *lady-bird*. All these insects deposit their eggs on the leaves of trees, and the *larvæ* produced are great devourers of plant-lice (*aphis*). They continue in the chrysalis state about a fortnight. Their wings, when they first burst their covering, are soft and dusky, but soon

become hard, and assume the various colours appropriate to the species. The lady-bird is celebrated for its reputed powers in the cure of tooth-ache; for which purpose one of these insects is to be crushed between the finger and thumb, which are then to be several times applied to the suffering part. Their virtue in effecting a cure depends on the same cause as that of Perkins's metallic tractors and other scenes of animal magnetism—the imagination of the patient.

**LAERTES**, son of Acrisius and Chalconethus, was one of the heroes engaged in the chase of the Caledonian boar, and in the expedition of the Argonauts. He afterwards married Euryclæa, the daughter of Autolycus, by whom he had several daughters and one son, Ulysses. He attained a great age. The long absence of his son, in the Trojan war, plunged him into deep melancholy; but his return restored the old man's energies, and he took part in the fight with the Ithacans.

**LÆTARE**; the fourth Sunday after Lent. The ancient Christian church used to begin its service, on this day, with the words *Lætare, sterilis, or Lætare, Jerusalem*.

**LAFAYETTE**, GILBERT MOTTEUR (formerly *marquis de*), was born at Chavagnac, near Brionne, in Auvergne, Sept. 6, 1757, was educated in the college of Louis le Grand, in Paris, placed at court, as an officer in one of the guards of honour, and, at the age of seventeen, was married to the grand-daughter of the duke de Noailles. It was under these circumstances, that the young *marquis de Lafayette* entered upon a career so little to be expected of a youth of vast fortune, of high rank, of powerful connexions, at the most brilliant and fascinating court in the world. He left France secretly for America, in 1777, and arrived at Charleston, South Carolina, April 25, being then nineteen years old. The state of America, it is well known, was, at that time, most gloomy; a feeble army, without clothing or arms, was with difficulty kept together before a victorious enemy; the government was without resources or credit, and the American agents in Paris were actually obliged to confess that they could not furnish the young nobleman with a conveyance. "Then," said he, "I will fit out a vessel myself;" and he did so. The sensation produced in America, by his arrival, was very great: it encouraged the almost disheartened people to hope for succour and sympathy from one of the most powerful nations in Europe. Immediately on his arrival, Lafayette received the offer of a command in the continental army, but declined it, raised and equipped a body of men at his own expense, and then entered the service as a volunteer, without pay. He lived in the family of the commander-in-chief, and won his full affection and confidence. He was appointed major-general in July, and, in September, was wounded at Brandywine. He was employed in Pennsylvania and Rhode Island in 1778, and, after receiving the thanks of the country for his important services, embarked at Boston, in January, 1779, for France, where it was thought that he could assist the cause more effectually for a time. The treaty concluded between France and America, about the same period, was, by his personal exertions, made effective, and he returned to America, with the intelligence that a French arm would soon be sent after him. Immediately on his arrival, he entered the service, and received the command of a body of infantry of about 2000 men, which he clothed and equipped, in part, at his own expense. His forced march to Virginia, in December, 1780, raising 2000 guineas at Baltimore, on his own credit to supply the wants of his troops; his rescue of Richmond; his long trial of generalship

with Cornwallis, who boasted that "the boy could not escape him;" the siege of Yorktown, and the storming of the redoubt, are proofs of his devotion to the cause of American independence. Desirous of serving that cause at home, he again returned to France for that purpose. Congress, which had already acknowledged his merits on former occasions, now passed new resolutions, Nov. 23, 1781, in which, besides the usual marks of approbation, they desire the American ministers to confer with him in their negotiations. In France, a brilliant reputation had preceded him, and he was received with the highest marks of public admiration. Still he urged upon his government the necessity of negotiating with a powerful force in America, and succeeded in obtaining orders to this effect. On his arrival in Cadiz, he found forty-nine ships, with 20,000 men, ready to follow him to America, had not peace rendered it unnecessary. A letter from him communicated the first intelligence of that event to congress. The importance of his services in France may be seen by consulting his letters in the Correspondence of the American Revolution (Boston, 1831). He received pressing invitations, however, to revisit the country. Washington, in particular, urged it strongly; and, for the third time, Lafayette landed in the United States, Aug. 4, 1784. After passing a few days at Mount Vernon, he visited Baltimore, Philadelphia, New York, Boston, &c., and was every where received with the greatest enthusiasm and delight. Previous to his return to France, congress appointed a deputation, consisting of one member from each state, "to take leave of him on behalf of the country, and assure him that these United States regard him with particular affection, and will not cease to feel an interest in whatever may concern his honour and prosperity."

After his return, he was engaged in endeavouring to mitigate the condition of the Protestants in France, and to effect the abolition of slavery. In the assembly of the notables, in 1787, he proposed the suppression of *lettres de cachet* and of the state prisons, the emancipation of the Protestants, and the convocation of the representatives of the nation. When asked by the count D'Artois, afterwards Charles X., if he demanded the states-general—"Yes," was his reply, "and something better." Being elected a member of the states-general, which took the name of *national assembly* (1789), he proposed a declaration of rights, and the decree providing for the responsibility of the officers of the crown. Two days after the attack on the Bastille, he was appointed (July 15) commander-in-chief of the national guards of Paris. The court and national assembly were still at Versailles, and the populace of Paris, irritated at this, had already adopted, in sign of opposition, a blue and red cockade (being the colours of the city of Paris). July 26, Lafayette added to this cockade the white of the royal arms, declaring at the same time that the tricolor should go round the world. On the march of the populace to Versailles (October 5 and 6), the national guards clamoured to be led thither. Lafayette refused to comply with their demand, until, having received orders in the afternoon, he set off, and arrived at ten o'clock, after having been on horseback from before day-light. He requested that the interior posts of the *château* might be committed to him; but his request was refused, and the outer posts only were intrusted to the national guards. This was the night on which the assassins murdered two of the queen's guards, and were proceeding to further acts of violence, when Lafayette, at the head of the national troops, put an end to the disorder, and saved the lives of the royal family. In the morning he accompanied them to Paris. (See *Louis XVI.*)

On the establishment of the Jacobin club at Paris, he organized, with Bailly, then mayor of Paris, the opposing club of Feuillans. Jan. 20, 1790, he supported the motion for the abolition of titles of nobility, from which period he renounced his own, and has never since resumed it. The constitution of a representative monarchy, which was the object of his wishes, was now proposed, and July 13, 1790, was appointed for its acceptance by the king and the nation, and, in the name of 4,000,000 national guards, Lafayette swore fidelity to the constitution. Declining the dangerous power of constable of France, or generalissimo of the national guards of the kingdom, after having organized the national militia, and defended the king from the popular violence, he resigned all command, and retired to his estates. The first coalition against France (1792) soon called him from his retirement. Being appointed one of the three major-generals in the command of the French armies, he established discipline, and defeated the enemy at Philippeville, Manbeuge and Florennes, when his career of success was interrupted by the domestic factions of his country. Lafayette openly denounced the terrible Jacobins, in his letter of June 16, in which he declared that the enemies of the revolution, under the mask of popular leaders, were endeavouring to stifle liberty under the excesses of licentiousness. June 20, he appeared at the bar of the assembly to vindicate his conduct, and demand the punishment of the guilty authors of the violence. But the Mountain had already overthrown the constitution, and nothing could be effected. Lafayette then offered to conduct the king and his family to Compiègne. This proffer being declined, he returned to the army, which he endeavoured to rally round the constitution. June 30, he was burned in effigy at the Palais-Royal, and, Aug. 5, was accused of treason before the assembly. Still he declared himself openly against the proceedings of August 10; but, finding himself unsupported by his soldiers, he determined to leave the country, and take refuge in some neutral ground. Some persons have charged general Lafayette with a want of firmness at this period; but it is without a full understanding of the situation of things. Conscious that a price was set on his head at home, knowing that his troops would not support him against the principles which were triumphing in the clubs and the assembly, and sensible that, even if he were able to protract the contest with the victorious faction, the frontiers would be exposed to the invasions of the emigrants and their foreign allies, with whom he would have felt it treason against the nation to have negotiated, he had no alternative. Having been captured by an Austrian patrol, he was delivered to the Prussians, by whom he was again transferred to Austria. He was carried, with great secrecy, to Olmütz, where he was subjected to every privation and suffering, and cut off from all communication with his friends, who were not even able to discover the place of his confinement until late in 1794. An unsuccessful attempt was made to deliver him from prison by Dr Bollman, a German, and Mr Huger (now colonel Huger of Charleston, S. C.). His wife and daughters, however, succeeded in obtaining admission to him, and remained with him nearly two years, till his release. Washington had written directly to the emperor of Austria on his behalf, without effect; but after the memorable campaign of Bonaparte in Italy, the French government required that the prisoners at Olmütz should be released, which was done Aug. 25, 1797, after a negotiation that lasted three months. Refusing to take any part in the revolutions of the 18th Fructidor, or of the 18th Brumaire, he returned to his estate at La Grange, and, declining the dignity of senator,

offered him by Bonaparte, he gave his vote against the consulate for life, and, taking no further part in public affairs, devoted himself to agricultural pursuits. On the restoration of the Bourbons, in 1814, he perceived that their principles of government were not such as France required, and he did not therefore leave his retirement. The 20th of March, 1815, again saw Napoleon on the imperial throne, and endeavouring to conciliate the nation by the profession of liberal principles. Lafayette refused, though urged, through the mediation of Joseph, to see him, protested against the *acte additionnel* of April 22, declined the peerage offered him by the emperor, but accepted the place of representative, to which the votes of his fellow-citizens called him. He first met Napoleon at the opening of the chambers: the emperor received him with great marks of kindness, to which, however, he did not respond; but, although he would take no part in the projects of Napoleon, he gave his vote for all necessary supplies, on the ground that France was invaded, and that it was the duty of all Frenchmen to defend their country. June 21, Napoleon returned from Waterloo, and it was understood that it was determined to dissolve the house of representatives, and establish a dictatorship. Two of his counsellors informed Lafayette that, in two hours, the representative body would cease to exist. Immediately on the opening of the session, he ascended the tribune, and addressed the house as follows:—"When, for the first time, after an interval of many years, I raise a voice which all the old friends of liberty will still recognise, it is to speak of the dangers of the country, which you only can save. This, then, is the moment for us to rally round the old tri-coloured standard, the standard of '89, of liberty, of equality, of public order, which we have now to defend against foreign violence and domestic usurpation." He then moved that the house declare itself in permanent session, and all attempts to dissolve it high treason; that whoever should make such an attempt, should be considered a traitor to the country, &c. In the evening, Napoleon sent Lucien to the house, to make one more effort in his favour. Lucien, in a strain of impassioned eloquence, conjured the house not to compromise the honour of the French nation by inconstancy to the emperor. At these words, Lafayette rose in his place, and, addressing himself directly to the orator, exclaimed, "Who dares accuse the French nation of inconstancy to the emperor? Through the sands of Egypt, and the wastes of Russia, over fifty fields of battle, this nation has followed him devotedly; and it is for this that we now mourn the blood of three millions of Frenchmen." This appeal had such an effect on the assembly, that Lucien resumed his seat without finishing his discourse. A deputation of five members from each house was then appointed to deliberate in committee with the council of ministers. Of this deputation, general Lafayette was a member, and he moved that a committee should be sent to the emperor to demand his abdication. The arch-chancellor refused to put the motion; but the emperor sent in his abdication the next morning (June 22). A provisional government was formed, and Lafayette was sent to demand a suspension of hostilities of the allies, which was refused. On his return, he found Paris in possession of the enemy; and, and, a few days after (July 8), the doors of the representatives' chamber were closed, and guarded by Prussian troops. Lafayette conducted a number of the members to the house of Lanjuinais, the president, where they drew up a protest against this act of violence, and quietly separated. Lafayette now retired once more to La Grange, where he remained till 1818,

when he was chosen member of the chamber of deputies. Here he continued to support his constitutional principles, by opposing the laws of exception, the establishment of the censorship of the press, the suspension of personal liberty, &c., and by advocating the cause of public instruction, the organisation of a national militia, and the inviolability of the charter.

In August, 1824, he landed at New York, on a visit to the United States, upon the invitation of the president, and was received, in every part of the country, with the warmest expressions of delight and enthusiasm. He was proclaimed, by the popular voice, "the guest of the nation," and his presence was every where the signal for festivals and rejoicings. He passed through the twenty-four states of the Union in a sort of triumphal procession, in which all parties joined to forget their dissensions, in which the veterans of the war renewed their youth, and the young were carried back to the doings and sufferings of their fathers. Having celebrated, at Bunker hill, the anniversary of the first conflict of the revolution, and, at Yorktown, that of its closing scene, in which he himself had borne so conspicuous a part, and taken leave of the four ex-presidents of the United States, he received the farewell of the president in the name of the nation, and sailed from the capital in a frigate named, in compliment to him, the *Brandywine*. Sept. 7, 1825, and arrived at Havre, where the citizens, having peaceably assembled to make some demonstration of their respect for his character, were dispersed by the *gendarmerie*. In December following, the congress of the United States made him a grant of 200,000 dollars, and a township of land, "in consideration of his important services and expenditures during the American revolution." The grant of money was in the shape of stock, bearing interest at six per cent., and redeemable Dec. 31, 1834. In August, 1827, he attended the obsequies of Marmont, over whose body he pronounced a eulogy. In Nov. 1827, the chamber of deputies was dissolved. Lafayette was again returned a member by the new elections. Shortly before the revolution of 1830, he travelled to Lyons, &c., and was enthusiastically received—a striking contrast to the conduct of the ministers towards him, and an alarming symptom to the despotic government. During the revolution of July, 1830, he was appointed general-in-chief of the national guards of Paris, and, though not personally engaged in the fight, his activity and name were of the greatest service. When the national guards were established throughout France, after the termination of the struggle, he was appointed their commander-in-chief, and his activity in this post was admirable. Aug. 17, he was made marshal of France. He however, sent in his resignation in December, 1830, which was accepted, and count Lobau appeared chief of the national guards of Paris. Lafayette declared from the tribune, that he had acted thus in consequence of the distrust which the power accompanying his situation seemed to excite in some people. On the same occasion, he also expressed his disapprobation of the new law of election. Shortly before his resignation, he exerted himself most praiseworthy to maintain order during the trial of the ex-ministers. The Poles made him first commander of the Polish national guards. He died on the 20th of May, 1834. The French Chamber of Deputies attended his funeral, and at Washington, the halls of the representatives and of the senate were closed in black.

Very few men have acted so conspicuous a part in life as Lafayette for so long a period. He was the heroic assertor of liberty, both in the new and old world,—in his youth and in his age; always an ardent

supporter of freedom and the rights of mankind, and, at the same time, a friend of law and order. Without entering into judgment on his political doctrines, it may safely be said, that history scarcely possesses a name, which has passed through the ordeal of public opinion, even in the darkest and most tempestuous times, more pure and unsullied than his. Regnault-Warin's *Mémoires sur le Général Lafayette* (Paris, 1824) contains many facts relative to his political life in France. His secretary, M. Levasseur, published an account of his tour in the United States (Paris, 1825), which has been translated in America.

LAFAYETTE, MARIA MAGDALENA, countess de; a lady of literary celebrity, daughter of the governor of Havre de Grace, Aymar de la Vergne. A careful and classical education had given her a great love for literature. In 1655, she married count Francis de Lafayette, and her house now became a place of meeting for the most distinguished men in her time. The famous duke of Rochefoucauld was one of her intimate friends. Among the learned men who surrounded her, the most distinguished were Huet, Ménage, Lafontaine and Ségrais. She died 1693. Her works entitle her to an honourable place among French writers. The most distinguished of them are *Zaide*, *La Princesse de Clèves*, and *La Princesse de Montpensier*.

LAFAYETTE MOUNTAIN. See *Haystack*.

LAFFITTE, JACQUES, a banker in Paris, member of the legion of honour, and, in 1816, elected to the chamber of deputies, a man equally distinguished for his talents, his wealth and his virtues, was born at Bayonne, in 1767, and, by his own diligence and merit, acquired a fortune in the banking-house of the senator Perregaux. In 1805, he became the head of the house, which he made one of the first houses in France. In 1809, he was appointed director of the bank of France, and, in 1814, president of the same establishment. He discharged the duties of this important office without accepting the large salary connected with it. In 1809, he was made president of the chamber of commerce in Paris, and, in 1813, judge of the tribunal of commerce. When the credit of France, in 1815, was at a very dangerous crisis, Laffitte advanced 2,000,000, in ready money, by which means a necessary article in the capitulation of Paris was settled. It was owing to his counsels, that France was enabled to support the burden of the military contributions imposed on her, without injury to the credit of the state. But when Laffitte joined the left side in the chamber of deputies, and opposed the encroachments of the infatuated absolutists, the laws of exception and the clergy, he became an object of hatred to the ultras, and of suspicion to the ministry. In 1819, he was deprived of the presidency of the bank, which was bestowed on the duke of Gaeta, with a large salary; yet he was, in 1822, unanimously re-elected to the office of *régent de la banque* (director). His eloquent speeches in the chamber, some of which were extemporaneous, proved his talent and knowledge, especially in the department of finance. He also spoke with energy on the occasion of the disturbances in Paris in 1819, when the young Lallemand was shot in the street by one of the watch, and old men, women, and children were trampled down by the *gendarmes*. He was not re-elected for the session of 1824. By favouring the reduction of the *rentes*, he appears to have lost his popularity. The chamber of deputies accepted the proposal for the reduction of the interest on the public securities then in circulation, but the chamber of peers rejected it. To prove the justice and advantages of this plan, and to justify his own conduct in the project, he wrote his *Réflexions sur la Réduction de la Rente et sur l'Etat du Crédit*, a financial work of much merit.

The second edition was published at Paris, in 1824. How great the confidence reposed in Laffitte was, the following fact will serve to show. When Louis XVIII. was compelled to flee, in 1815, he intrusted his private property, for safe keeping, to Laffitte; three months after, Napoleon, under the same circumstances, showed him the same confidence, and, at St Helena, named him his executor. As Napoleon, in the hundred days, had respected the private property of Louis, so Louis XVIII. respected that of the emperor, and put no obstacles in the way of the execution of his last will. Among the merits of Laffitte, his great benevolence to the poor ought not to pass unnoticed. The publishers of the Latin classics, at Paris, were also assisted by him in carrying on their useful undertaking. Laffitte was, in 1827, again elected to the chamber of deputies. His only daughter was married, in 1828, to the prince of Moskwa, eldest son of the celebrated marshal Ney. He took an active part in the revolution of July, 1830, being one of the deputies who signed the protest, and declared themselves deputies of France, in spite of Polignac's order to annul the election. Laffitte was also one of the deputies, who, during the fight on July 29, went to marshal Marmont, in order to put a stop to the conflict. November 3, 1830, he was made minister of finance and president of the council, in which situation he remained until March 14, 1831, when he was succeeded by M. Casimir Perrier, belonging to the left centre. Laffitte suffered immense losses in consequence of the fall of stocks since the revolution of July, 1830.

LAFITAU, JOSEPH FRANCIS; a French Jesuit, who was a native of Bordeaux, and was employed as a missionary among the savages of North America. On his return to Europe, he published a work, entitled *Mœurs des Sauvages Américains comparées aux Mœurs des premiers Temps* (Paris, 1724, 2 volumes, 4to); and another on the Discoveries and Conquests of the Portuguese in the New World (1733, in 2 vols., 4to). In the former, he maintains that the North American savages are descended from the barbarians who inhabited Greece at an early period. He died in 1740.

LAFITTE; a Bordeaux wine. See *Bordelais Wines*.

LAFONTAINE, JEAN. See *Fontaine, la*.

LAFONTAINE, AUGUSTUS HENRY JULIUS, the most fertile and one of the most popular novelists of Germany, was born in 1756, in Brunswick. He studied theology, and, in 1792, accompanied the Prussian army into Champagne, in the capacity of chaplain. He lives now at Halle. His novels are entertaining, but not distinguished by merit of a high order. Of late, he has occupied himself with *Æschylus*, and published *Agamemnon* and the *Cœphori*, with judicious notes (Halle, 1821 et seq., 2 vols.), in which he sets forth some peculiar views respecting the text of this author.

LAGO MAGGIORE, or LAKE MAJOR, or LOCARNO (anciently *Verbanus*); a large lake in Italy, separating the Austrian government of Milan from the Sardinian Milanese, extending from Sesto to Locarno; about forty-five miles long, and seven broad. It is 636 feet above the level of the sea, according to Saussure, and, in some places, 1800 feet deep. It is traversed by the Ticino. Its waters, which are as clear as crystal, contain various fish. Its banks abound in every Alpine beauty, and are adorned with a number of picturesquely situated villages and towns. On all sides it is surrounded by hills, planted with vineyards and plantations of chestnuts, interspersed with villas. There are several islands, two of which, Isola Bella and Isola Madre, called *Borromean islands*, are laid out in gardens

and pleasure grounds, with palaces erected on them, adorned with paintings, sculptures, &c. *Isola de' Pescatori* is inhabited by fishermen. See *Borromei Islands*.

**LAGO NERO, or NEGRO;** a town in Naples, in Basilicata, at the foot of the Appenines, near a lake from which it receives its name; twelve miles north-east of Policastro; population, 5000. In March, 1806, a battle was fought here between the French and the troops of the king of Naples, in which the former were victorious.

**LAGOON** (from the Latin *lacuna*, a ditch) means a *morass*. The name is given particularly to those creeks which extend along the coast of the Adriatic, in the present government of Venice, and which are formed by water running up in the land. They contain many islands; Venice, for instance, is built on sixty of them. In some places, they are deep; in others so shallow, that their exhalations are offensive and dangerous. The Austrian government does less towards clearing them out than the former Venetian government did; and Venice, in consequence, is considerably less healthy than it was. Towards the sea, the islets are secured by dams, natural or artificial.

**LAGRANGE, JOSEPH LOUIS**, a celebrated mathematician, was born in 1736, at Turin, and originally directed his attention to philosophy. But his natural taste for mathematics soon unfolded itself, and he studied with such ardour, that, in his eighteenth year, in a letter to the celebrated Pagnano, he communicated to him a number of mathematical discoveries which he had made. He also solved the questions, which had been proposed a long time before, by Euler, on the calculation of isoperimetrical figures, and on the theory of the least action. When scarcely nineteen years of age, Lagrange was made mathematical professor in the artillery school at Turin; and the memoirs of the scientific association, which he established with the approbation of the government, and in conjunction with the celebrated Cigna and the marquis of Saluces, excited such attention in the literary world, that he was elected a fellow of the academy at Berlin, and Euler, and D'Alembert entered into a constant correspondence with this young man. During a journey to Paris, which he made in company with his friend Caraccioli, who was sent as an ambassador to London, Lagrange became personally acquainted with the Parisian *savants*, and was received with general respect. But ill health soon obliged him to return home, where he applied himself with renewed diligence to his scientific labours. At this time, he obtained the prize of the academy of sciences in Paris, for a treatise on the theory of the satellites of Jupiter, and, at the same time, by his exposition of the leading features of his doctrine in regard to the planetary system, rendered his name immortal. He soon after received an invitation from Frederic the Great, to go to Berlin, with the title of director of the academy, in place of Euler, who had gone to St Petersburg. The king of Sardinia was, however, very reluctant to permit his distinguished subject to depart. Esteemed by the great Frederic, who preferred his independent spirit to the somewhat too submissive character of Euler, and valued highly by all who became acquainted with him, Lagrange lived in Berlin in pleasant circumstances (which were interrupted, however, by the continual sickness of his wife), during the lifetime of the king. After Frederic's death, the regard which had been paid to men of genius and talent at the Prussian court declined, and Lagrange began to look about for another situation. At this period, Mirabeau saw him in Berlin, and resolved to obtain this renowned geometer for France. Lagrange accepted the offers

made him from Paris, and declined the proposals of the ambassadors of Naples, Sardinia, and Tuscany. He was received at Paris, in 1787, with the highest tokens of respect. But a deep melancholy seemed to have taken entire possession of him, and to have palsied his mind, notwithstanding all the efforts which his friends made to remove it. He suffered the same inconvenience which D'Alembert had once before experienced, viz. of having lost all love for his science. Lagrange now zealously employed himself upon the history of religion, the theory of ancient music, languages, and even the medical sciences. His own favourite science alone had no attraction for him, and he even suffered his most celebrated work, *La Mécanique analytique* (for which Du Châtelet, to whom Lagrange had given the manuscript, was for a long time unable to find a publisher, it is untouched for two years after its publication. At the proposal of Du Séjour, he was, in 1791, commissioned by the national assembly in his pension of 6000 francs, and, in order to indemnify him for the depreciation of the paper currency, he was first appointed a member of the committee for rewarding useful inventions, and, afterwards (in March, 1792), one of the directors of the mint. Dissatisfied with this station, although Cicero and Newton had discharged similar offices, he soon resigned it, considering it as an oppressive burden. In the same year, he was married, for the second time, to a daughter of the *sensational* Lemonnier, hoping to lead a tranquil life in the midst of the storms of the revolution. The decree of October 16, 1793, commanding all foreigners to leave France, and the execution of Bailly, Lapouze, and other distinguished men, soon, however, destroyed his illusions. Through the instrumentality of Guyon Morveau, the severe law of banishment from the country was not put in force against him; but the danger of becoming a victim to the rage of the infuriated populace remained. Hérald de Sécherre offered to procure him a place in an embassy to Prussia, but Lagrange, who had conceived a warm affection for his new country, preferred to remain there in spite of the danger. Peace and quiet at length returned. It was proposed to restore the institutions for the promotion of learning, which had been destroyed during the reign of anarchy, and Lagrange was appointed professor in the newly established normal school at Paris. In this new sphere of influence, his former love for his science returned with all its strength. At the formation of the institute, the name of Lagrange was the first on the list of members, and he was, likewise, the first member of the newly constituted bureau of longitudes. His fame now increased from day to day, and France, feeling honoured in the possession of such a son, determined to give him a public mark of her esteem. By the command of the directory, the minister of foreign affairs, Talleyrand, commissioned the French *chargé d'affaires* in Turin, citizen D'Eymar, to visit Lagrange's father, and congratulate him, in the name of France, in having such a son. This commission was performed by D'Eymar in the most brilliant manner, accompanied by several generals and other distinguished persons. Napoleon respected the talents and services of Lagrange not less than the republic had done; and while consul and emperor, he never ceased to show him distinguished tokens of his favour in every possible way. Member of the senate, grand officer of the legion of honour, and count of the empire, Lagrange saw himself surrounded with every external honour; but neither this, nor the confidence reposed in him by the head of the state, could make him vain, and, as modest and retiring as ever, he devoted himself with the same zeal and industry to his studies. His application

probably hastened his death. Notwithstanding his advanced age, he could not be content to relax his exertions, and had superintended the publication of the second edition of his *Théorie des Fonctions analytiques*, enriched with annotations, when, exhausted by his labours, he died, April 10, 1813. His remains were interred in the Pantheon. Lacépède and La Place pronounced funeral addresses over his body.

Lagrange was no less amiable than modest, and was never led by the honours bestowed upon himself, to underrate the merits of others. His respect for Euler was unlimited, and he was frequently accustomed to say to his scholars, "Study Euler, if you would become geometers." His works have been partly published separately, and are partly contained in the memoirs of the academies of Turin, Berlin, and Paris, in the Journal of the Polytechnical School, the *Connaissance des Temps*, and in the *Ephémérides*. The most important are his *Mécanique analytique* (Paris, 1787; new editions, 1811, and 1815); *Théorie des Fonctions analytiques* (Paris, 1797, and 1813); *Résolutions des Equations numériques* (Paris, 1798, and 1808); *Leçons sur le calcul des Fonctions* (there are several editions of this work, but the latest is that of Paris, 1806), and *Essai d'Arithmétique polémique* (to be found in the collections edited by Reeder, in 1796). A part of Lagrange's posthumous papers were, in 1815, given to the institute, by Carnot, minister of the interior; and by a subsequent vote of the academy of sciences, they were incorporated with the library of that learned society.

LAGUS. See *Ptolemy*.

LAHARPE, JEAN FRANÇOIS DE; a French dramatic poet, critic, and philosopher of the last century, born at Paris, November 20, 1739. His father, a Swiss officer in the French service, dying in indigence, Asselin, president of the college of Harcourt, admitted him into that seminary, where he received an excellent education. A lampoon on his benefactor, which was, in all probability without foundation, attributed to him, occasioned the confinement of the suspected satirist for some months in the Bastille. This circumstance disgusted him with his situation, and, at a very early age, he threw himself on his own talents as an author for support. In 1762, he published a collection of poems. The tragedy of *Warwick* (1763) was very beneficial to him in a pecuniary point of view, and procured him considerable reputation. It still remains on the stage. His *Timoleon* and *Pharamond* met with less success; but a series of *éloges* on Charles V., Catinat, Fénelon, Voltaire, and Henri Quatre (especially the latter), gained him much credit, in a different department of literature. On the breaking out of the revolution, Laharpe embraced the principles of republicanism; but, during the reign of terror, his moderation rendering him an object of suspicion to those then in power, he was thrown into prison in 1793, and, while in confinement, is said to have owed his conversion to Christianity to the arguments of his fellow-captive, the bishop of St Brieux. Though sentenced to deportation, the changes of the times finally restored him to liberty, and he passed the remainder of his days in literary retirement. A short time before his death, his remarks on the measures of the government excited the displeasure of the first consul, and he was banished to Orleans. He soon returned, however, and died in 1803, in his 64th year. His principal work is the *Lyce*, or a complete Course of Literature (8vo, 12 vols). Among the rest are *Gustavus Vasa*, *Timoleon*, *Pharamond*, and *Philoctetes*, tragedies; the latter an elegant translation from the Greek of Sophocles. *Tungu et Féline* (a poem, 1779); *Translations of Camoens' Lusiad* (2 vols); the *Palms*

of David, and the works of Suetonius (2 vols); a Commentary on the dramatic Works of Racine (7 vols, 8vo); the Correspondence with the Czar Paul the First (4 vols, 8vo), and a refutation of the opinions of Helvetius.

LA HOGUE; the north-western point of the peninsula, near Cherbourg, in the department La Manche. A naval battle was fought here May 29, 1692, between the French, under Fourville, and the British and Dutch, under Russel. The French were beaten. James II. beheld the battle from the land, and was obliged to witness the defeat of his party.

LAHYRE (properly *Etienne Vignoles*); a brave knight in the reign of Charles VII. of France, and the faithful companion of the maid of Orleans. Lahyre hated the English bitterly, as his family had been ruined by their invasions. In 1418, when Coucy was surrendered to the Burgundians, the allies of the English, in consequence of the treachery of the mistress of the commandant, Lahyre and the equally brave Peter de Xaintrailles placed themselves at the head of the remnant of the garrison, and successfully led their little band, in the midst of constant skirmishes, through a country filled with enemies. After many valiant deeds in Valois, and in Champagne, Lahyre hastened to the relief of Orleans. The government of the town sent him with a petition to the dauphin, Charles VII., to implore his assistance. He found the weak and pleasure-loving prince preparing for an entertainment. "What are your thoughts?" said Charles to the knight, who viewed with indignation the frivolity of the court. "I think," replied Lahyre, "that a kingdom could not be lost more merrily." Returning to Orleans, he did his utmost to save the town, and to assemble the relics of the beaten army. In 1429, the maid of Orleans appeared. Lahyre joined her, and was with her at her entrance into the town. He followed the defeated English, and distinguished himself in the battles of Jargeau and Patay. In the middle of winter, he stormed Louviers, and advanced to Rouen with the intention of liberating the imprisoned Joan; but the English took him prisoner. He soon, however, obtained his liberty, and renewed his exertions, with Xaintrailles, against the enemy. To his death, Lahyre was the most inveterate enemy of the invaders of his country, and injured them greatly. He was repeatedly taken prisoner, often by the treachery of false friends; but he always succeeded in liberating himself: for a time, he even braved his own king, continuing a petty warfare against the English and the Burgundians, and garrisoning several towns, although Charles had concluded a peace. On a journey to Montauban, where he accompanied Charles VII., in 1442, he died in consequence of his wounds. His romantic valour, together with his attachment to the maid of Orleans, procured him, after his death, the honour of having his name added to the knave of hearts in the French playing cards; the pictures of which are, as it is well known, designated by the names of different heroes.

LAING, MAJOR ALEXANDER GORDON, one of the many unfortunate explorers of Africa, was born at Edinburgh on the 27th of December, 1793. His father was a popular classical teacher in that city, and young Laing, after receiving a good education, employed himself, for some time, in taking charge of the commercial department of his father's academy.

In 1800, volunteering was very general in Edinburgh, and Laing attached himself to a corps then forming. In 1810, he was made an ensign in the Prince of Wales' volunteers, and from that period the academy had no more charms for him. In his eighteenth year he set off for Barbadoes to his maternal uncle, then colonel Gordon, who at that time held the

office of deputy quarter-master-general in Barbadoes, and who gave him a situation as clerk in his counting-house. While in this situation he obtained, unsolicited, an ensign's commission in the York light infantry, and joined his regiment in Antigua: in two years he was made a lieutenant, and shortly after, on the reduction of the regiment, was put on half-pay. Dissatisfied with the inactivity consequent on such a measure, he exchanged into the 2nd West India regiment, and proceeded to Jamaica. Here over-exertion caused him to suffer much from disease on the liver. He retired to Honduras for the recovery of his health, where he was appointed fort major. His distemper, however, returned with increasing violence, and compelled him to seek relief in the air of his native land.

During eighteen months that he remained at home, the division of the 2nd West India regiment to which he belonged, was reduced, and he was again put on half-pay. Restored, however, to health, he could not remain inactive. Towards the end of 1819, he went to London, and having been appointed lieutenant and adjutant of his regiment, he proceeded to Sierra Leone.

From the beginning of the year 1822 his history as an *African traveller* may properly be dated. In that year he was despatched on two several important embassies to Kambia and the Mandingo country. Having been led to believe, during his last embassy, that the Soolimas were in possession of quantities of gold and ivory, he suggested to the governor of Sierra Leone the propriety and probable advantages of the colony opening up a commercial intercourse with them; and the suggestion having been approved of, he left Sierra Leone on the 16th of April, 1822, with the view of furthering such an object, accompanied by two Europeans, and thirteen natives of Africa. On his arrival at Komato, the last town of the Koorankoes, on his route, he found a messenger from the king of Soolimana, with horses and carriages to convey him to Falaba, the capital of that nation. Not long after reaching Falaba, lieutenant, now captain Laing (for about this time he was promoted), was seized with a fever which brought on delirium for several days. While in this state he was cupped by one of the Soolima doctors, and this so effectually as to satisfy him that it was the means of saving his life. Although within three days' journey of the source of the Niger, he was not permitted to visit that often sought spot, and deep was the grief which the loss of such an opportunity cost him. On the 17th of September he quitted Falaba, and had no sooner reached Sierra Leone than he was ordered to join his regiment on the Gold coast without delay, in the war with the Ashantees, which order he obeyed, after having transmitted details to his friend, captain Sabine in London, of the geographical determinations of the latitude, longitude, and elevation of the places he had lately visited.

In 1824 he was sent home, to acquaint government of the state of the Ashantee country, and the circumstances of the war. An opportunity having unexpectedly presented itself to him, of proceeding under lord Bathurst's auspices, in the discovery of the course and termination of the Niger, he gladly embraced it; and it was arranged, that he should accompany the caravan from Tripoli to Timbuctoo, in the ensuing summer. Our traveller, now promoted to a majority, left London for Tripoli, in the month of February, 1825. While in the latter city he had occasion to have frequent intercourse with the British consul, Mr Warrington; a close intimacy was formed between them, and the bond was strengthened by the major's marrying Emma Maria, the daughter of the consul. This event was celebrated on the 14th of

July, 1825; and two days after the marriage the major proceeded on his pilgrimage to Timbuctoo.

He left Tripoli in company with the sheik Baham whom he afterwards discovered to be no less a personage than the governor of Ghadamis. After a tedious and circuitous journey of nearly a thousand miles, they arrived at Ghadamis; and on the 31 of December reached Ensala, a town said to be thirty-five days' journey from Timbuctoo, and from which he wrote the last letter to his relations in Scotland, which they ever received from him. He quitted Ensala on the 10th of January, 1826, and on the 26th of the same month entered on the sandy desert of Tenesaroff. Hitherto the elements only had been his foes; but in the desert he was to enter on a different course of experience, and bitter assuredly it was. In an engagement with the Turries he received no less than twenty-four sabre wounds, and on recovering from his wounds, he was seized with fever.

On the 18th of August he arrived at Timbuctoo, and made himself acquainted with many interesting particulars regarding that capital of central Africa. After remaining there about two months, he set out on his return, but was assassinated on the way, Sept. 1826, and all his valuable papers stolen. Much mystery for some time existed regarding the death of this unfortunate and enterprising traveller; but from facts elicited at Tripoli in 1829, it would appear that the very guide (Bahani), who set out with him on his expedition, was under the secret direction of Hassunah D' Ghies, son of the prime minister of the Tripolitan bashaw, and the conspirator against the major's life—that by his (D' Ghies') instructions the ferocious Bourabouschi, the eventual murderer, was appointed to be the conductor of the major from Timbuctoo, and that into his (D' Ghies') hands the major's papers were put by another of his emissaries shortly after the murder.

It would further appear that the documents referred to were given by D' Ghies to the French consul at Tripoli, the baron de Rousseau, and that during the greater part of the major's journey this official from France had been in secret correspondence with the conspirators—that he exerted himself in securing the flight of Hassunah D' Ghies after the treachery had been discovered, and gave protection to, and assisted with his brother Mohammed, who made the disclosure. It were out of place, in this memoir, to detail the strong chain of evidence by which these allegations are supported. A masterly summary of it will be found in the Quarterly Review, No. 84.

LAING, MALCOLM, a Scottish lawyer and historian, was born at Strynsna, his paternal estate, on the mainland of Orkney, in 1762. He was educated at Kirk wall, whence he was removed to the university of Edinburgh, after which he studied law, and was called to the bar. His first literary production was a completion of the last volume of Dr Henry's History of Britain (1793). He afterwards published a History of Scotland from the union of the crowns to the union of the kingdoms, in 4 vols. 8vo. This work contains many searching investigations on disputed points of history, in which the author, with a generous liberality, always adopts the unpopular or unpopular view of the subjects. His last literary undertaking was an edition of the poems of Ossian, to which he prefixed a dissertation, which is generally considered to have set the question at rest as to their want of authenticity. Mr Laing served in parliament under the short administration of Mr Fox, to whose politics he was attached. He died in 1818.

LAIRESSE. There was a family of Flemish painters of this name, of whom Gerard, son of the elder Lairese, has acquired by far the greatest reputation. He was born in 1640, at Lierge. He is

particularly distinguished by the high finish with which his pictures are executed, and is considered the Raphael of the Dutch school; nor have any of his countrymen ever equalled him in historical painting. This talented artist was also a good engraver, and understood music scientifically, while of his literary abilities he has left a favourable specimen, in a treatise on the principles of his art. He survived the loss of his sight some years, and died, at length, at Amsterdam, in 1711. His book has been translated into English. His three brothers, *Ernest*, *John*, and *James Lairese*, were artists of some note, the two former excelling in the delineation of animals, the latter in flowers. Two of his sons also followed the profession of their father, but with inferior ability.

**LAIS**; a celebrated courtesan, daughter of Timandra, the mistress of Alcibiades, born at Hyccara, in Sicily. She was carried away from her native country to Greece, when Nicias, the Athenian general, invaded Sicily. She began to sell her favours at Corinth for 10,000 drachmas, and an immense number of princes, noblemen, philosophers, orators, and plebeians, did homage to her charms. The high price which she demanded of her lovers gave rise to the proverb *Non cuius homini contingit adire Corinthum*. Even Demosthenes himself visited Corinth for the sake of Lais; but when he heard the courtesan name her price (a sum equal to about £212, 10s.), the orator departed, and observed that he would not buy repentance at so dear a rate. The charms which had attracted Demosthenes had no influence upon Xenocrates, although Lais (Phryne?), seeing the philosopher unmoved by her beauty, visited his house herself. Diogenes the cynic was one of her warmest admirers, and, though slovenly in his dress and manners, yet he gained her heart. Lais ridiculed the austerity of philosophers, observing that the sages and philosophers of the age were found at her door as often as the rest of the Athenians. The success which she met at Corinth encouraged her to pass into Thessaly, particularly to enjoy the company of a favourite youth called Hippostratus; but the women of the place, jealous of her charms, and apprehensive of her corrupting the fidelity of their husbands, assassinated her in the temple of Venus, about 340 years before the Christian era.—Pausanias mentions another Lais, likewise a courtesan.

**LAÏUS**. See *Œdipus*.

**LAKE**. Lakes are large bodies of inland water, having no direct communication with seas or the ocean, or communicating with them only by rivers, by which they pour out their superabundant waters. Some lakes have no issue, and receive no streams; but these are generally very small. Some have outlets, but receive no running waters; these are fed by springs which are thus obliged to fill up a basin before their waters can find their way downward towards the lower country. Others receive and discharge large rivers, and sometimes a chain of lakes are connected with each other, and with the sea, by a series of rivers. This is the case with the great lakes on the northern frontier of Amiens, which are, in reality, a series of large basins or reservoirs, receiving the accumulated waters of the surrounding countries, and pouring them out through successive channels into other basins situated on a lower level. (See the articles *Superior*, *Huron*, &c.) Another class of lakes receive large streams or rivers, but have no visible or apparent outlet. The Caspian sea, lake Titicaca, &c., are examples of this kind. These masses of water are sometimes drained by subterraneous streams, and are sometimes kept at their ordinary level by the ordinary process of evaporation. Some lakes are raised to a great height above

the level of the sea. Lake Superior is 641 feet above the ocean. The waters of lakes are generally sweet, but there are some, such as the Caspian, &c., which are salt. All the great American lakes are of fresh water.

**LAKE OF THE WOODS, or DU BOIS**; a lake of North America, seventy miles long, and forty wide. Large quantities of oak, fir, pine, spruce, &c., grow on its banks; hence its name. It contains a few small islands, and communicates with lake Winnipeg, which discharges its waters into Hudson's bay. Lon. 95° 20' W.; lat. 54° 30' N.

**LANDE, JOSEPH JEROME LE FRANÇAIS DE**, one of the most distinguished astronomers of the last century, was born of a respectable family, at Bourgen Bresse, in France, July 11, 1732. Educated with a minute attention to religious duties, he displayed his abilities when very young, by composing sermons and mystical romances. The remarkable comet of 1744 first drew his attention to the heavenly bodies; and his taste for astronomy was fixed by the observations of father Beraud, mathematical professor at the college of Lyons, on the great eclipse of July 27, 1748. He wished to become a Jesuit, that he might devote himself entirely to study; but his friends, objecting to this plan, sent him to Paris, where he studied the law, and was admitted an advocate. He became acquainted with Delisle, who had established an observatory in the house in which he resided, and obtained permission to assist him in his operations. He also attended the lectures on astronomy delivered by Messier, at the *collège de France*, and obtained the friendly patronage of Lemonnier, who lectured on natural philosophy at the same college. The academy sent him to Berlin to make observations for the purpose of determining the parallax of the moon, while Lacaille went to the cape of Good Hope for the same purpose. At the sight of so young an astronomer (for he was scarcely nineteen years of age), Frederic the Great could not conceal his astonishment. Lalande, however, proved himself worthy of the choice of the academy at Paris, and was not only received at court, but was made a member of the academy of Berlin. After having finished his operations at Berlin, he was chosen member of the academy of sciences in Paris, in the year 1753. Thenceforward no volume of their transactions appeared which did not contain some important communications from him; nor did he confine his labours to astronomical subjects merely. The French are indebted to him also for an edition of Halley's tables, as well as for the historical account of the comet of 1759. For the identifying of this remarkable comet, he presented to Clairault the deepest and most ingenious calculations. As the editor of the *Connaissance des Temps*, he entirely changed the plan and management of this useful work, and thereby set a good example to his successors. In 1761, he produced a chart, which showed the phases of the remarkable transit of Venus over the sun's disk for all places on the globe. In 1764, he published his *Astronomie*—a classical work, which was afterwards printed in three volumes quarto, and reached the third edition, and of which he made an abridgment (*Abrégé d'Astronomie*, published at Paris in 1795)—a work which cannot be too highly recommended to lovers of this science. In 1765 and 1766, he made a journey to Italy; a description of which (in eight vols. 12mo) contains much valuable information. He composed all the astronomical articles for the great *Encyclopédie*, and also wrote them anew for the *Encyclopédie méthodique*. In 1761, he succeeded to his first instructor, Lemonnier, in the astronomical professorship of the *collège de France*, where he knew how to give to his lectures a peculiar

attraction. His lecture room was a kind of nursery, from which a multitude of his scholars were transplanted to the directorship and management of domestic and foreign observatories. His work *Des Canaux de Navigation et spécialement du Canal de Languedoc* (1778 folio) contains a general history of all the ancient and modern canals, which had previously been undertaken, accomplished, and even projected. Such a work had, till then, been a desideratum, and this is now of the greatest advantage to the engineer. His *Bibliographie astronomique* (1 vol. 4to.) is a copious catalogue of all the works that had ever appeared on the subject of astronomy. As he was a member of all the great academies, he formed, as it were, a common bond of union between them, while he communicated, from one to the other, whatever each one produced worthy of notice. His activity was remarkable. Lalande enjoyed for a long time a splendid reputation; but his imprudent freedom, the independence with which he expressed his opinion in the most turbulent times, the often offensive severity which he was accustomed to use against systems which deserved no notice, and the habit of publicly declaring his sentiments where he might better have been silent,—all this made him numerous enemies, who persecuted him, and succeeded so far, that his real merit has been called in question. His character was, in fact, a strange mixture of great and commendable qualities united with striking singularities, which may have proceeded from vanity and the desire to attract attention. Lalande, however, was kind, generous, full of feeling, and, in his own way, religious, although his enemies accused him of atheism. His death took place April 4, 1807.

LALLY, THOMAS ARTHUR, count; a brave, but imprudent and unfortunate Irish officer in the service of France. He was of a family which had followed the fortunes of James II., and, having entered the French army, he signalized himself so much in the battle of Fontenoy, that he was made a brigadier-general on the field of battle. He also drew up the plan of a descent upon Britain, which would have been tried but for the defeat of Charles Edward at Culloden. In 1756, he was selected to restore the French influence in India, for which purpose he was made governor of Pondicherry. It was soon perceived, however, that he wanted the prudence, moderation, and disinterestedness necessary for so distant and critical a scene of action; and, after a little partial success against the English, in the first instance, he was finally obliged to retire to Pondicherry, which was besieged and taken by the British, January 16, 1761, the garrison, with Lally, being made prisoners of war. On this catastrophe, a torrent of invective assailed the unfortunate leader from all quarters, he having offended every body concerned, by his haughty humour, and violent temper and conduct. He was even accused of having sold Pondicherry to the British, notwithstanding the avowed hatred which, as a Jacobite, he felt for them. He arrived a prisoner of war in Britain, in September, 1761, and, the following month, was allowed to return to France, where, after a long imprisonment, he was brought to trial for treachery, abuse of authority, and unjust exactions. Being found guilty, he was condemned to be decapitated, which sentence was executed May 6, 1766, in the sixty-eighth year of his age. In 1778, his son, Lally-Tollendal, obtained possession of the estates of his father, with a revival of the proceedings, which were manifestly unjust, count Lally being one of the victims to public clamour, like admiral Byng, and many more who have been sacrificed to the unpopularity of an incapable administration.

LALLY-TOLLENDAL, TROPHIME GERARD,

marquis of, son of the preceding, born at Paris, March 5, 1751, devoted himself to the military profession. He soon made himself known by his writings in defence of his father's memory, and embraced the cause of the revolution with alacrity, but, at the same time, with prudence. During the increasing popular excesses, he joined his friend Mounier in Switzerland. From hence he returned, but was arrested, and escaped almost by a miracle the massacre of September. He thereupon fled to England, and, while in that country, offered his services as the defender of Louis XVI., but was not accepted. After the 18th Brumaire, he returned to France, took an active part in public affairs, under Louis XVIII., and was by him called to the chamber of peers, where he has often defended moderate principles with true eloquence. He was also a member of the French academy. He died at Paris, in March, 1830.

LAMA (in the Tangutian dialect, *mother of souls, pastor of souls*) is, among the Mongols, the appellation of all the members of the priestly order; but among the Calmucs it signifies only the most distinguished. Hence the religion of the Mongols and Calmucs is called *Lamaism*. In this religion the Shigemooni is honoured as the highest God, and the Dalai-lama (i. e. the great lama), as his representative. He is at the head of both ecclesiastical and secular affairs in Thibet, which may be considered as a theocratical state. He is considered not as a mere visible representative of the divinity on earth, but as a real divinity himself, dwelling among men. The belief in his eternal existence is connected with the doctrine of the transmigration of souls. His worshippers believe that the divinity, as soon as it leaves the body of the Dalai-lama, immediately takes possession of some other body in a supernatural way, so that he only changes his exterior form, and not his actual existence. Among a people who possess such a regular hierarchical system, it is a matter of small consequence who stands at the head. The usual residence of the Dalai-lama is in two monasteries situated in the vicinity of the capital, Lassa, in each of which he dwells alternately. He is surrounded in every direction by a vast number of priests; but no woman is permitted to pass the night in the building where he lodges. This arises, undoubtedly from the purity which is attributed to him; for he is called the *immaculate*. The natives, as well as a great crowd of foreigners (for all the Mongol tribes in Russia acknowledge him), undertake fatiguing pilgrimages in order to pay their homage to him, and obtain his blessing. He receives them sitting upon a kind of altar, upon a large and splendid seat, with his legs crossed. The Tartars, sent to the inhabitants of Thibet, pay him the greatest reverence. They come to him from the most distant regions, and the princes, to whom he shows no more respect than to others, submit to the same ceremonies as their people. He salutes no one, never touches his head, rises up before no one, and is satisfied with laying his hand upon the head of his worshipper, who believes that he has thereby obtained the pardon of his sins. His worshippers believe that the supreme divinity lives in him, that he knows and sees every thing in the deepest recesses of the heart, and never needs to make inquiry in regard to any thing. If he does this, it is only that unbelievers and the evil-minded may not have cause for complaint. He sometimes distributes, it is said, little balls of consecrated dough, which the Tartars use in many superstitious practices; but it is not true, that balls made from his excrement are distributed, preserved in golden boxes, and even mixed with articles of food. His power was once greater than it is now, and he

appointed and deposed the khans; but he is now more dependant on the emperor of China, although the latter, in a religious respect, is subjected to him. Two Chinese mandarins, with a garrison of 1000 Chinese, are maintained in his capital, and, in the palace at Pekin, the Chinese emperor supports a subordinate lama, who is sent as a nuncio from Thibet. When the Dalai-lama dies, it is then necessary to discover where his spirit has chosen to be born anew. In this case, all must submit to the opinion of some of the lamas, who alone are acquainted with the signs by which he may be known, or, rather, who know what child the deceased has appointed for his successor. The worshippers of the lama are divided, in general, into two sects, known by the titles of the *yellow* and *red caps*. Each sect is under three lamas; the former is under the Dalai, Teeshoo, or Bogao, and Taranaut lamas; the latter, under the three shammas. The Dalai-lama is the most distinguished of all, and next to him is the Teeshoo-lama, who dwells at Teeshoo-Loomboo ten days' journey from Lassa. The three shammas dwell in separate monasteries, the most distinguished of which is at Tassasudon, the capital of Bootan. Subordinate to them are numerous priests of different ranks, who are held in great respect, who superintend instruction, and some of whom live in a state of celibacy, according to certain rules, similar to those of the Christian monks. At Lassa alone there are 3000 monasteries. The religion of the lama sprung up in Thibet, and knows no eternal, self-existent being. Their idols or Boorchans, 108 in number, are created beings, who ascended into the rank of gods before the present world was created, on account of their holiness. Shigemoomi, the chief object of worship, appeared in the world for the last time 1000 B. C., and instituted Lamaism, and now rules the world in its present state of misery. The earth is inhabited by degenerate spirits from the upper world. The human soul, after it has been subjected to a state of trial, and has passed a good or bad life, enters upon a higher or lower condition. This doctrine renders the worshippers of the lama benevolent and moral. Their idol worship consists in clamorous songs and prayers, accompanied with loud music, in splendid and festive processions, and in the solemnisation of certain festivals at fixed times, together with pilgrimages and personal castigations.

LAMA, in zoology. See *Llama*.

LAMARCK, JEAN BAPTISTE ANTOINE PIERRE MONET, chevalier de, was born in the year 1745, in Picardy, of a noble family, and was compelled, on account of an accident, to abandon the service, and devote his attention to study. He applied himself at first to medicine; afterwards, in consequence of hearing Jussieu's illustrations of botany, was led to the study of natural science. Jussieu, on a botanical excursion, in which Lamarck accompanied him, had imagined that the old method of instruction in this department left much to be wished for, and Lamarck determined to remedy this deficiency. He laboured with great diligence on a treatise in which he showed the defects of the old system, and proposed a new one for himself, which met with universal approbation. He then applied his new system to the plants of France, and delivered to the academy his *Flore française, ou Description succincte de toutes les plantes que croissent en France*. This work was adopted, by the recommendation of the academy, at the expense of the government, for the benefit of the youth (1780, under the date of 1778, in three vols.; second edition, 1793; and the third enlarged and revised by Decandolle, in 1805). Lamarck now devoted his whole attention to this science, and made several botanical excursions to Auvergne and into

Germany, in the last of which he was accompanied by the son of the great Buffon. On his return to Paris, he undertook the botanical department of the Encyclopædia, which Panckoucke was publishing, and applied himself to this task with such assiduity, that, in 1783, he produced the first half of the first volume, with an introduction, containing a sketch of the history of the science. He published the second volume in 1788. But a dispute between him and the publisher, in regard to the admission of certain articles, brought the undertaking to a stand, and there ended Lamarck's botanical career. Many of his botanical treatises were published in the *Memoirs of the Academy*, and in the *Journal d'Histoire naturelle*, edited by him, together with the abbé Haüy, Fourcroy, Bruquière, Oliver and Pelletier, which make us regret that their author ever abandoned this branch of science. At the breaking out of the revolution, he was the second professor in the royal *jardin des plantes*; but, in consequence of new arrangements, he was made professor in the department of zoology, in which he was soon as much distinguished as he had been in botany. His *Système des Animaux sans Vertèbres, ou Tableau général des Classes, des Ordres, et des Genres, de ces Animaux* (one vol., Paris, 1801), his *Philosophie zoologique*, and his *Histoire naturelle des Animaux sans Vertèbres*, are his principal works in this department of science. Lamarck's comprehensive mind was also directed towards physics, and he published, in 1794, *Recherches sur les Causes des principaux Faits physiques*, in which he exposes many false theories in this science. With the same view, he also wrote his *Refutation de la Théorie pneumatique*, &c., which appeared at Paris in 1796. He collected his meteorological observations in his *Annuaire météorologique*, which first appeared in 1799, and was continued to 1809.

LAMARQUE, MAXIMILIAN, was born at Saint-Sever, of rich and respectable parents, and, in 1792, entered the army as a private soldier, choosing to obtain promotion only by merit, and became captain of grenadiers in the celebrated corps of Latour d'Auvergne, known under the title of the *infernal column*. He was in the vanguard of the army of the Pyrenees, in 1793, under the command of general Moncey, and received, Feb. 3, two severe wounds, while, with a single company, he was sustaining the attack of a column of the Spanish army, that endeavoured to turn the French division. He afterwards marched against Fontarabia, at the head of 200 grenadiers, and, precipitating himself into the moat, drew down the drawbridge, and gained possession of the place. Eighty pieces of cannon, and 1800 prisoners, were the fruit of this *coup-de-main*, which procured Lamarque, then but twenty years old, the rank of adjutant-general. In 1801, he was made general of brigade, and distinguished himself at the battle of Hohenlinden. He then served in Spain, and in the campaign of 1805, so brilliantly terminated by the battle of Austerlitz. He was soon afterwards sent to Naples with the army under the command of Joseph Bonaparte, and, in crossing the mountains on the Neapolitan frontier, with eight soldiers, was attacked by a band of fifty robbers, under the orders of the ferocious Fra-Diavolo, against whom he successfully defended himself. He was sent, in 1807, against the insurgents of Calabria, and, near Marathæa, defeated a body of 1200 British that were sent to support them. He took the town, and made 1800 prisoners, which exploit gained him the rank of general of division. He was employed by Murat in 1808, and took the island of Caprea from the British, which was considered impregnable, and was defended by a garrison superior in numbers to the assailants. He afterwards joined the army in Germany, and at the

battle of Wagram, had four horses killed under him. He served in Russia and in Spain in 1812, and, after the evacuation of the Peninsula, returned to France, and was created a knight of St Louis, July 27, 1814. On the return of Napoleon, he was appointed to the first military division, as commander-in-chief of the army of the Loire. In his operations against the insurgents of La Vendée, he distinguished himself not less by his forbearance and humanity than by his decision, and, after obtaining some successes at La Roche-Serviere, he effected a pacification at Chollet. After the return of the Bourbons, he was comprised in the second article of the law of July 24, 1815, and retired to Saint-Sever, under the inspection of the minister of police. He afterwards took refuge at Brussels, but was ordered from thence by the king of the Netherlands, upon which he passed into Austria. In 1815, he published a Defence of General Maximilian Lamarque, in a manly, bold and candid tone. In 1818, he was permitted to return to France, and, in 1820, produced an able pamphlet On the Necessity of a Standing Army. General Lamarque was afterwards a conspicuous member of the chamber of deputies, and, in the late revolution in France, zealously adopted popular principles. He died at Paris in May, 1832.

LAMBERT, JOHN HENRY, an eminent mathematician and astronomer, was born at Muhlhausen in the Sundgau, a town then in alliance with the Swiss cantons, August 29, 1728. His father was a tailor, in humble circumstances, who intended him for his own business; but, being sent to a public school, he so distinguished himself, that an attempt was made to provide him with the means of studying theology, which, however, proved unsuccessful, and he was obliged to follow his father's employment. In this situation, he spent the greatest part of the night in study, and, obtaining an old mathematical treatise, discovered so much ardour and ingenuity, that several learned men were induced to instruct him gratis. He acquired a knowledge of mathematics, philosophy, and the Oriental languages in his native place. He afterwards became clerk to some iron works, and amanuensis to M. Iselin of Basle, who conducted a newspaper, and became his sincere and constant friend. In 1748, this gentleman recommended him to baron Salis, president of the Swiss convention, to become tutor to his children; and, aided by the excellent library of his new patron, and the scientific intercourse which he met with in his circle, he enlarged the sphere of his acquirements in an extraordinary degree. After living eight years at Coire, during which period his talents as a philosopher and mechanic were rendered manifest by various scientific compositions and inventions, he repaired, in 1756, with his pupils, to Gottingen, and soon after published his first separate work, entitled *De la Route de la Lumière par les Aïrs*. In 1758, he visited Paris with his charge, and became acquainted with D'Alembert and Messier. In 1759, he went to Augsburg, where he published his celebrated work *On Perspective*; and in the following year appeared his *Photometry*, by which he added a new branch to the science of mixed mathematics. In the three or four following years, he published *Letters on the Construction of the Universe*; a *Treatise on the principal Qualities of the Orbits of the Comets*; *Novum Organon*. In 1764, he visited Berlin, and was introduced to Frederic the Great, who admitted him a regular member of the academy of that capital—an appointment which enabled him to devote himself wholly to his favourite studies. He enriched the transactions of various societies with his papers and treatises, all of which bear the stamp of eminent and original genius. Most of his mathe-

matical pieces were collected, in three volumes, by himself. His death took place September 25, 1777, in his forty-ninth year, owing to a decline, produced by over-application. Lambert furnishes one of the most conspicuous examples on record of the mastery with great genius and energy will sometimes exert over untoward circumstances. In mathematics, logic, and metaphysics, he was highly distinguished. He was accustomed to labour from five in the morning till midnight. He discovered the theory of the speaking trumpet. Philosophy, and especially analytic logic, are greatly indebted to him for his *Novum Organon*, or *Thoughts on the Examination and Relations of Truth* (Leipsic, 1764, 2 vols.); his *Architektonik*, or *Theory of the first Principles in philosophical and mathematical knowledge* (Riga, 1771, 2 vols.).

LAMBETH; a village in Surry, England, on the borders of the river Thames, opposite to Westminster. Here is a palace belonging to the archbishop of Canterbury, a very large pile of building, containing a library of 25,000 volumes, and upwards of 1200 manuscripts. The kings of England, down to Henry VII., often resided at Lambeth, in a palace which no longer exists. Population in 1831, 67,465. See *London*.

LAMEGO; a city of Portugal, in Beira, in a plain near the Duero, surrounded by mountains, thirty-six miles E. of Oporto; long. 7° 27' W; lat. 41° 7' N.; population, 9000. It contains two cathedral churches, a hospital, four convents, a theological seminary, and a library. In this town the estates assembled (1144) to confirm the election of Alphonso Henriques, first king of Portugal, and enacted the fundamental laws of the kingdom. See *Portugal*.

LAMENTATIONS. See *Jeremiah*.

LAMETTRIE, JULIEN OFFRAY DE, a materialist and medical charlatan, was born at St Malo, in 1732, and studied medicine in Holland, under Boerhaave. He then went to Paris, where the duke de Gramont, colonel of the guard, appointed him physician to his regiment. He followed his patron to the siege of Freyburg, and was here taken dangerously ill. He believed that the spiritual power, which is called the soul, perishes with the body, and wrote a *Naturelle de l'Âme*. This work, which every where breathes the grossest materialism and scepticism, procured him many enemies, and was burned by the executioner, at the command of Parliament. On the death of his patron, he lost his place. He then turned his arms against his Parisian colleagues, and wrote, under the signature Altheus Democritus, his satire of *Pénélope ou Machiavel en Médecine* (Berlin, 1748), on account of which he was obliged to fly to Leyden. Here he published his *L'Homme Machine*. The philosophy of the author consists in constant assumptions of what he is attempting to prove, in perfect comparisons or analogies instead of proofs, some just observations from which general conclusions are illogically drawn, and assertions instead of doubts. Being persecuted in Holland, where his book was condemned to the flames, he went to Berlin, in 1748, and was made a reader to the king, and a member of the academy. He died in 1751, of a fever, which he treated after his own absurd system. The king of Prussia himself wrote his eulogy, which was read in the academy. We find, in the works of Lamettrie, spirit and a brilliant imagination, but little judgment, accuracy, or taste. His philosophical writings appeared at Berlin, in 1731, in two volumes. His writings, besides the above-mentioned, are *L'Homme Plante*, *L'Art de Jouir*, *De Discours sur le Bonheur*, and others. In the latter work, Lamettrie is, according to Diderot, an author

without judgment, one who confounds the ills of the wise and good with the torments of the wicked, and the slight evils of knowledge with the destructive consequences of ignorance—who betrays his frivolity in what he says, and the corruption of his heart in what he dares not speak out—who in one place asserts that man is evil by nature, and elsewhere derives man's duties and his happiness from the nature of his being—who seems to labour to console the criminal in his crimes, the vicious in his vices—and whose gross sophisms, dangerous on account of the jests wherewith he seasons them, betray a man ignorant of the very rudiments of moral philosophy. Voltaire, who had at first favoured him, retracted his encomiums. On his death bed, Lametrie manifested strong marks of penitence.

**LAMIA**; the name of an Athenian courtesan, celebrated for the charms of her person, and the brilliancy of her wit. She was, by profession, a flute-player. Hearing that her favourite instrument was carried to great perfection in Egypt, she travelled into that country, where she became the mistress of Ptolemy Soter. On the defeat of that prince by Demetrius Poliorcetes, about three centuries before the Christian era, Lamia fell into the hands of the conqueror, over whom, the handsomest man of the age, she soon acquired a complete ascendancy. Her influence procured from Demetrius great concessions in favour of her countrymen, the Athenians, who, in their gratitude, went so far as to raise a temple to her honour, under the denomination of *Venus Lamia*. Plutarch and Athenæus both bear ample testimony to the qualities of her mind; and, if the antique engraving on an amethyst, in the king of France's collection, give a true portrait of her features, her beauty is still less questionable. The exact time of her decease is uncertain.

**LAMIAE**; in fabulous history, certain monsters of Africa, who had the face and breasts of a woman, and the rest of the body like that of a serpent. They allured strangers to come to them, that they might devour them; and, though they were not endowed with the faculty of speech, yet their hissings were pleasing and agreeable. Some believed them to be witches, or rather evil spirits, who, under the form of a beautiful woman, enticed young children and devoured them. According to some, the fable of the *Lamia* is derived from the amours of Jupiter with a certain beautiful woman called *Lamia*, whom the jealousy of Juno rendered deformed, and whose children she destroyed; upon which *Lamia* became insane, and so desperate, that she ate up all the children that came in her way. These beings are also called *Lemures*. (q. v.)

**LAMIAN WAR**; a war carried on by the troops of Antipater (323 B. C.), after the death of Alexander, when the Greeks rose against Leonatus, who was sent to the fortress of *Lamia*, in Thessaly. The consequence of this war was the abolition of the Grecian democracies, and the reception of Macedonian garrisons into the cities. Athens was also obliged, to conclude a peace, to give up Demosthenes and Hyperides, the orators who had instigated them in this war. Demosthenes destroyed himself by poison.

**LAMOIGNON**. See *Maleherbes*.

**LAMOTTE VALOIS**, countess of, rendered notable by the affair of the necklace, represented herself the descendant of the family of Valois, by an illegitimate child of Henry II. Until the affair of the necklace, she had lived in misery and contempt, though she had employed all the arts of immorality and intrigue, to procure for herself rank and wealth. Being thus known to a great part of the nobility of Versailles and Paris, she astonished all who were

acquainted with the circumstances of her fortune, when, in 1784, she suddenly began to display an extravagance which could only be supported by great wealth. An intrigue soon became notorious, which attracted the attention of all Europe. The prince Louis de Rohan, cardinal bishop of Strasburg, and grand almoner, had fallen into disgrace, of which the reasons were not very satisfactorily known. The countess of Lamotte, informed of the desire of the cardinal to recover favour at court at any price, had falsely represented to him, that the queen, with whom she pretended to have a great, though secret influence, wished to possess a costly necklace, which was offered for sale, but at that time was not able immediately to advance the sum requisite for the purchase. If, therefore, he would purchase the necklace in his own name, and allow the queen to repay him by instalments, he would by so doing regain favour. The cardinal fell into this snare, purchased the necklace, and gave it to the countess of Lamotte, to be delivered by her to the queen. A bond, forged by the countess, was then given him for his security, settling the conditions of payment. In order to deceive the cardinal the more perfectly, the countess had concerted with a woman who was privy to the plot, that she should appear to him under the mask of the queen, in August, 1784, in the gardens at Versailles, and present him a box containing a rose and the queen's portrait. The time when the cardinal had promised to pay for the necklace now came, and, as he did not possess money sufficient for the purpose, he informed the jewellers, that the necklace was purchased for the queen. The jewellers, after waiting a long time without obtaining their money, applied to the king, and thereby gave a clue for the detection of the fraud. By the sentence of parliament, the deceived cardinal was acquitted, and the countess of Lamotte, convicted of having embezzled and sold the necklace, was sentenced to be branded, scourged, and perpetually imprisoned. After nine months, she escaped confinement, and fled to England, where, in conjunction with her husband, who had there sold the necklace, she published a pamphlet against the court of Versailles, and particularly against the queen. Villetta and Cagliostro, who had taken part in the deception, were banished the kingdom. The countess was found, after a nocturnal revel, precipitated from a third story window upon the pavements of London.

**LAMP**. The invention of lamps is ascribed to the Egyptians. In the festivals in honour of Minerva, at Sais, in Lower Egypt, great numbers of lamps were kept burning. They were known even in the times of Moses and Job. The Egyptians were also the first who placed burning lamps in the tombs with their dead, as an emblem of the immortality of the soul. From Egypt, the use of lamps was carried to Greece, where they were also consecrated to Minerva, the goddess of learning, as indicative of the nightly studies of the scholar. From Greece, the use of lamps passed to the Romans. The first person who is known to have published a collection of ancient lamps, is Fortunio Liceto, an Italian, whose chief design appears to have been to prove the possibility of the existence of inextinguishable, or, rather, perpetually-burning lamps. Pietro Santo Bartoli, a countryman of his, afterwards published at Rome, in the year 1691, the collection of Bellori; but these engravings are exceedingly ill executed and unfaithful. Passeri, however, another Italian, published, at the suggestion of the academy of Pesaro, a collection of 322 lamps which he possessed in his museum. The above-mentioned collections, however, have been much surpassed in beauty and interest by that of Portici. The sixth hall of that museum is entirely filled with lamps and candelabras discovered in the

houses of Pompeii and Herculaneum. Representations of these were published in 1792, in ninety-three copper-plates, exclusive of vignettes. They form the ninth volume of the *Antiquities of Herculaneum*. We find there represented and explained upwards of two hundred lamps and candelabras of bronze and terra-cotta. The ancients appear to have very early acquired the practice of using lamps. The use of oil was not perhaps known to the Romans in very remote ages, although the Greeks, unquestionably, were acquainted with it, as appears from several passages in Herodotus. We find, indeed, the figure of the lamp sculptured and engraved on many of the most ancient Greek vases. It is with a lamp that Mercury, as depicted on one of these, lights Jupiter, who is represented scaling with a ladder the chamber of Alcmena. Baked earth was the substance of which the earliest lamps were composed, but subsequently we find them of various metals—of bronze more particularly. A few ancient lamps of iron are also extant; but these are rare, either because that metal was little used for the purpose, or on account of its more ready destruction in the ground. There are four specimens in the museum of the king of Naples, at Portici, where there is likewise one specimen of a lamp of glass. It is entirely solid, and in one single piece. Pausanias mentions a golden lamp in the temple of Minerva, and St Augustine speaks of lamps of silver. No antique of either kind, however, has reached modern times. The testimony of Pliny, St Augustine, and others, has led to the belief that the ancients had perpetual lamps, and Liceti has composed his work to establish this supposition. Different authors mention instances of lamps, which, in modern times, have been found burning in ancient sepulchres, but were extinguished as soon as the external air was admitted. The most famous instance is that of the tomb of Tulliola, daughter of Cicero, discovered at Rome, in 1540. None of these instances, however, can be considered as proved. The idea probably arose from the inflammation of the hydrogen gas contained in these caverns, when explorers entered them with torches. The lamps or candlesticks made use of by the Jews, in their own houses, were generally put into a very high stand on the ground. The lamps supposed to have been used by the foolish virgins, &c., in the gospel, were of a different kind. According to critics and antiquaries, they were a sort of torches made of iron or potter's earth, wrapped about with old linen, and moistened, from time to time, with oil. (*Matt.* xxv., 1, 2.) The lamps of Gideon's soldiers were of the same kind. The candlestick, with seven branches, placed in the sanctuary by Moses, and those which Solomon afterwards prepared for the temple, are said to have been crystal lamps filled with oil, and fixed upon the branches. Among the Romans, also, it was customary to have the lamp either depending from the ceiling, or placed on a stand in the room, since the use of tables was not common to them, and their attitude in studying, as well as at their repasts, was a half-recumbent one, holding their scroll or tablets before them on their knees. These stands were often highly ornamented. The most common form of them was a tripod with lion's feet, from which sprang sometimes the shaft of a column, according to one of the orders of architecture, the disk placed to receive the lamp forming the capital. These vessels were generally ornamented with mythological or allegorical subjects, and their shape varied greatly. Sometimes it was a simple disk with a hole in the circumference, through which to pass the wick, and another in the middle, to pour the oil into. At other times they presented the appearance of a boat. Occasionally their extremity terminated in two or three divisions, according to the

number of beaks; but it would be endless to attempt to pursue these details. Inscriptions were likewise often found placed upon them. (See *Candelabra*.) Public illuminations on occasions of national rejoicing were common to the Romans. On the birthdays of their princes, on great religious solemnities, &c., they suspended lamps at the windows. Juvenal and Persius both make mention of this usage. Various motives have been assigned for the ancient practice of placing lamps in sepulchres. One of the most ingenious, and perhaps the most satisfactory, is that it was allegorical of the cessation of mortal life—of the separation of the soul, which the ancients regarded as an emanation of fire. On some sepulchral lamps we find sculptured the figure of the butterfly, in allusion, no doubt, to the equally cheerful and elegant metamorphosis of the escape of the spirit, in a more ardent semblance, from its chrysalis state. The early Christians adopted, in their monuments, this pagan usage together with many others, and the lamp has been found in the tombs of saints and martyrs, and of distinguished men who embraced Christianity. In these instances, it was, no doubt, meant still more to be illustrative of that divine flame by which they were inspired, and whose inward light guided them through the many savage persecutions suffered by the primitive followers of our holy faith. The shapes of ancient lamps, as well as other ancient utensils, have been imitated with much success by Mr Wedgwood. The principal works to be consulted on the subject of lamps are those already quoted, of Liceti, of Bellarmino, and of Passeri; *Antichità d'Ercolano*, volume 9 (Lucerne); a *Dissertation sur une Lampe antique trouvée à Munich en 1753*, written by the prince de St Sévère on the question of inextinguishable lamps; and the preliminary remarks to the description of antique lamps found at Nîmes, in vol. 3d of *Mémoires des Monumens Inédits*.

We now come to speak of the construction of the lamps of modern times, but before describing them it will be necessary to say a few words on the nature of flame. Various substances, during combustion, afford a permanent and luminous flame, the degree of illumination depending upon the nature of the substance. It was the opinion of Sir H. Davy, that the brilliancy of flame, was owing to the intensity of the combustion of the gaseous matter, towards the interior, in consequence of charcoal being produced and strongly ignited, before it is burned. Those bodies that, during combustion, emit chiefly carbon, or volatile matter, give out flame of little brilliancy, as hydrogen and sulphur; those, on the other hand, which emit solid substances, such as oil, yield a brilliant white flame. In a conical flame, as that of a candle, combustion takes place more intensely at the surface, where the inflammable matter comes into contact with the air. At the bottom of the flame there is a dark portion, where the volatile matter has not yet been wholly set on fire; while, in the middle the flame is brightest, in consequence of the volatile matter being brought to a white heat before it is burned.

In order to ensure a constant and steady flame, the supply of combustible matter must be adequate and uniform; wherefore it must either be in a liquid or gaseous state, so that it may approach the flame, as an uninterrupted current. The combustible may be made to approach the flame either by capillary action through means of wicks, or by mechanical pressure.

The requisite properties for a perfect lamp are—1st, It must be supplied with carbonaceous matter, and with oxygen; 2nd, It must convert the former into a gaseous state; and, 3rd, it must bring the gas, so produced, in contact with oxygen, at such a temperature, that the carbon will combine with the oxygen.

in the fullest degree, to produce the greatest quantity of flame without any smoke.

To make a lamp burn with a clear and steady light, the length of wick standing up above the tube or nozzle, which supports the wick, must be regulated according to its capacity for conducting the oil, otherwise the whole of the oil which it supplies will be volatilized by that portion of flame which surrounds the lower part of the wick. In this case, the upper part of the wick, which is in the centre of the flame, will burn to a charcoal or snuff.

A snuff in the centre of the flame, produces a smoke, and a great diminution of light, which it occasions, by increasing the body of the wick; and as the air cannot have free access to the wick in the centre of the flame, the gas there produced cannot burn immediately, but must rise upwards, and will inflame when it gets high enough to meet the air, provided it then retains a sufficient heat. This ascent of the vapour before it inflames, is the cause of the pyramidal form of the flame; the vapour arising from the central parts of the wick being obliged to rise to a greater height before it can meet with sufficient oxygen to burn. On the other hand, a wick, which is too little raised above the nozzle will not volatilize the oil so fast as it draws it up; still what is volatilized is perfectly burned, and smoke is not produced.

A torch is composed of the resinous part of fir or pine, and the turpentine, or melted rosin, oozes through the pores of the wood to the flame, in a slow and regular manner, producing a dull light. The candle is an improvement upon the torch, and consists, as every one knows, of a few threads of cotton or other fibrous substance called a wick, enveloped in a cylinder of tallow or wax. Flame being communicated to the wick, combustion begins, and the radiated heat melts the tallow nearest to the wick, and it ascends to the flame through the wick by capillary action, being converted into gas so soon as it reaches the surface, which gas enters into combustion, and a bright flame is the consequence. A common lamp acts on the same principle, but the combustible employed being a liquid, a vessel is necessary to contain it. The common liquid employed in this country is whale oil, on the continent oil of poppies, nuts, rape seed, and the inferior kinds of olive oil, are used. Naphtha is also used. In some cases the vessel is open at top, and the wick projects from a sort of beak in the side; but the usual plan now is to close the top of the vessel with a cover, and lead the wick up through a hole in the middle; but here a small opening must be left, to admit the pressure of the air, so that the oil may rise in the wick. In this latter construction, if the vessel be large, a dark broad shadow will be thrown below the lamp, and much light lost. To avoid this, lamps have been made with the vessel or reservoir containing the oil, placed at a considerable distance from the burner. Among contrivances of this nature, the Astral or Simulbral lamps, invented by count Rumford, are the most esteemed. In count Rumford's lamp, the oil is contained in a hollow circular ring, the oil being led to the burner, which is in the centre, by means of radiating tubes. The ring is placed somewhat below the level of the flame, and a small hole is made in the upper surface for the admission of air. The supply of oil has sometimes been effected upon the principle of Hero's fountain. In this lamp, it is placed in a vessel having a tube leading downwards for some distance, then turning up a little it enters another vessel. A syphon rises from the top of this second vessel, and enters a third vessel higher than the first, from which third vessel an inverted siphon is led up to the burner. Oil is put into the first, and falls gradually down into the second, and

oil is placed in the third, there being a column of air between the second and third vessels. As the oil from the third vessel becomes exhausted, the column of oil from the first vessel presses upon the column of air communicating with the second and third vessels, and thus raises the oil to supply the burner. Other lamps are constructed so as to keep the surface of the oil at one level, by placing it in one leg of an inverted syphon, and balancing it with some heavier fluid, such as salt water, in the other leg.

In France, the oil is kept at the proper level by pumping the oil up, either occasionally by the hand, or by clock work; a clumsy contrivance. This is much better accomplished in the simple and ingenious lamp of Mr Porter. In this lamp the oil is contained in an oblong box, having the wick tubes at one end, and being suspended on an axis, nearer the wick end than the other, so that when it is full, the additional quantity of oil at the longer end will just balance the additional weight of the wick tubes. It is clear that as the oil is burned away, the wick end of the box will fall, and the oil rise to the burner.

Fountain lamps are constructed on the same principle as the bird fountain used in cages. The large reservoir is open at the bottom, a tube being placed there at one side. This tube is immersed at the outer extremity, in a small cavity containing oil, nearly on a level with the burner. Whenever the oil in the cavity falls under the level of the top of the tube, a bubble of air enters, and rising to the top of the reservoir, presses down more oil to the cavity, and thus the wick is constantly supplied.

A very simple kind of lamp is used to burn all night in sick chambers: a small quantity of water is poured into a glass tumbler, and above that a quantity of oil. A bit of cork is now pierced, so as to admit a few threads of cotton to pass through it, and the cork being placed upon the oil will float, the cotton threads will draw up the oil by capillary action, and a feeble but clear light will be given. A glass tube of small bore will answer instead of the cotton threads.

The great defect of common lamps is that the wick being thick, the air can only come into contact with a comparatively small portion of the flame. This is in some measure rectified by spreading out the wick so as to form a broad thin flame. But the most important improvement in the form of wicks and burners was made by M. Argand of Geneva, in 1784. The annexed wood engraving is a sectional view of Argand's lamp. A is the oil

Fig. 1.

vessel, acting on the principle of the bird fountain, having a neck at the bottom, and being closed at the top by a lid, which is lifted when the vessel is to be supplied with oil, the neck being at that time held uppermost. The oil is poured in by the small opening *t*, which is uncovered by sliding the tube *Q*, and when filled, the tube is restored to its former position, and the vessel *A* placed in its seat *F*. When by the consumption of the oil the surface in *F* is lower than the opening, then a bubble of air ascends into *A*, and the oil falls, until the opening *t* is covered by the oil in *F*; as by reason of the heating of the air within the vessel *A*, more oil will come down than is necessary for the supply of the wick, which surplus oil is allowed to fall down to the cup *P*, through the tube *g*, which cup is screwed to the bottom of the tube *d*. The burner or cylindrical part, containing the cylindrical wick, consists of three concentric tubes, *d*, *f*, *g*. The tube *g* is fixed by solder to the bottom of the tube *d*, and the space between them is occupied by the cylindrical cotton wick steeped in oil. The oil flows from the large vessel through *N*, and enters the cavity between the exterior surface of the tube *g*, and the interior surface of the tube *d*, rising to the level of the opening *t*. There is a short tube, *i*, which receives the wick, and is made so as to slide easily up and down on the tube *g*. The wick tube has a projecting pin inwards, which fits into a spiral groove cut in the tube *k*, so that when the wick tube is turned round, the pin moving in the spiral groove, causes the wick tube to rise or fall, and consequently the wick itself. The wick tube is connected with the outer tube *f*, by means of a catch, so that by turning this latter tube, the height of the wick can be regulated at pleasure. On the outside of the tube *d*, a ring, *rs*, is fixed, which supports the glass chimney *R G*. There is a wire *s* attached to the tube *f*, and bent over the edge of the tube *d*, and *rs* is connected with four wires which attach it to a ring *q*, surrounding the tube *d*, by turning which ring, therefore, the wick is raised or depressed. The air which supports the combustion on the outside of the flame, enters through the holes *m m*, in the ring *rs*, and the combustion in the interior part of the flame, is supported by the air which enters the holes *o o*, and passes up through the tube *g*. The subjoined wood cut, fig. 2, represents the exterior form of an argand lamp, with count Rumford's circular ring oil vessel, in which lamp, there is besides the small chimney, a large hemispherical vessel, ground rough on the inner surface, and resting on the oil ring

Fig. 2.

Fig. 3.

Sir Humphry Davy invented a safety lamp for going light in mines where fire-damp prevails. He found that a lamp constructed with an envelope of wire gauze, the apertures of which occupy greater space than the solid wire, would not cause explosion in fire-damp. The wire gauze should not contain fewer than 784 apertures in the square inch, and the wire should be either iron or copper, but by no means brass. Fig. 3, exhibits a view of the safety lamp as commonly constructed. *A* is the oil column, *B* is a brass rim firmly attached to the wire gauze cylinder *F*; *C* is the feeder, through which oil is passed into the lamp; *E* is a wire which passes through a safe tube in order to trim the wick; *G* is a brass cap on the top of the cylinder of gauze, the cap bears about 3-4ths of an inch above the gauze cover of the cylinder; *I I* are strong wires to strengthen the lamp, and *K* is a ring to hang the lamp by.

Fig. 4, represents a self generating gas lamp. *I* is a hollow ring for containing oil on Count Rumford's principle. The oil passes from this funnel

Fig. 4.

down the tubes *B B*, and enters the upright tube to a height equal to the height of the ring. At the part of the upright tube there is a shallow cup or rounding it. At a distance of rather more than an inch above this, there is a thin brass cap fitted at the top of the tube *C*, the cap being narrow at the bottom, and ground so as to fit accurately on the tube; above this sort of ring, at the bottom of the cap, it widens into a bulb, perforated with twelve small holes, as jets, and the upper part is a straight tube closed at the top. There is a tube *D* at the bottom, which, by being turned round, acts in a screw, and raises or depresses the oil in the tube *C*, so that it stands at the proper level. Now, a small quantity of alcohol or common spirits being put into the cup, on a level with the ring, and set on fire, will heat the tube *C* to such a degree, that the oil within it will boil, and gas will be evolved. The gas rises into the cap on the top of the tube, not having any other way of escape, issues out of the holes in the side of the cap, and the alcohol continues still to burn, sets fire to the jets, and a series of beautiful clear lights is the result. The heat of the gas lights themselves, is sufficient to keep the oil boiling, so that the flame acts not only as a light, but as a self generator. A considerable quantity of carbon is deposited on the outside of the tube, which may be prevented by slipping on screw-down washers, which being stripped off when the lamp is trimmed, the former deposition of carbon will be removed.

**LAMPADEPHOROI** (Gr. *λαμπας*, a torch, and *φορος*, to carry). In the torch-races of the ancient Greeks, the successful competitor was called *λαμπαδοφορος*, and the race itself, *λαμπαδοδρομια*. These races took place in Athens, at the *Fulcanalia*, *Promethea*, *Panathenaea*, and some other festivals. The runners were three youths. It was decided by lot who should begin. He commenced his race, and, if his torch was extinguished before he reached the goal, he gave it to the second, and this one, in a similar case, to the third. He who carried the torch burning to the goal, was the victor (*λαμπαδοφορος*). If a youth ran too slow, in order to avoid extinguishing his torch, the spectators drove him on by beating him with the open hand. The poets often allude to the delivery of the torch from one to the other.

**LAMPBLACK.** See *Carbon*.

**LAMPREY** (*petromyzon*). This fish has a long and slender body, resembling that of the eel. The skin has no scales, but is covered with a glutinous mucus. The sea-lamprey, which is sometimes the largest species, grows to a very large size, having been seen of five or six pounds weight. Its colour is dusky, irregularly marked with dirty yellow. In the mouth are placed twenty rows of small teeth, disposed in circular order, and placed far back near the throat, four, five, and six in each row. The *branchiæ* are situated within seven apertures that exist on each side of the neck. This fish, as its name indicates, possesses the power of sucking, and adhering to stones. The mouth is of a round form, resembling that of a leech, and, like that animal, it can adhere to any substance with great firmness. The sea-lamprey, although properly an inhabitant of salt water, like the salmon and other marine fish, is found at certain seasons of the year in rivers. The lamprey was at one time considered as a great delicacy by the English; and a surfeit on them caused the death of Henry I. In the reign of Henry IV., so highly were they esteemed, that protections were granted to such vessels as might bring them in; and his successor issued a warrant to William of Nantes, for supplying him and his army with this article of food, wherever they might happen to march. The lamprey is still considered as a delicacy at certain seasons of the year, but has lost much of its value as an article of food. During cold weather, this fish conceals itself in the crevices of rocks; and it is a usual expedient with anglers to form pits extending to the water side in the vicinity of its haunts; into these a little blood is thrown, to induce the lamprey to come forth, when it is readily taken. The lamprey, so celebrated among the epicures of ancient Rome, appears to have been a fish of another genus—the *muræna*, or *murenophis*. This fish, with the bass (*lupus*), and a species of mullet (*myxus*), formed the pride of Roman feasts—the *tripatinum*. (See *Pliny, lib. 35, cap. 12.*) These lampreys were reared with the greatest care, and at an enormous expense, in artificial fish-ponds. Pliny gives some curious details on this head; he says, Lucullus formed a fish-pond, near Naples, of such size, that the fish it contained, after his death, sold for 4,000,000 of sesterces (170,000 dollars); but Hirrius was the first to build a pond for lampreys alone. On one occasion, when Cæsar gave an entertainment to the people, Hirrius furnished him with 6000 of these fish. They also appear to have been kept as pets; thus the celebrated orator Hortensius wept bitterly at the death of a lamprey, and Antonia, the wife of Drusus, ornamented one with jewels. The bite of the *muræna* was deemed so poisonous by the fishermen, that they adopted great caution to prevent its effects, seizing the animal by the head with a forceps, and rubbing its snout against some hard substance to

destroy its teeth, and beat it on the tail, where (as is now supposed with regard to eels), it was thought that the life resided. There are several other species of lampreys and murænas, some of which inhabit the American coasts and rivers, for information on which we refer to doctor Mitchell's papers on the *Fishes of New York* (New York Phil. Trans.) and Mr Lesueur's on *American Murænas* (Jour. Acad. Nat. Sci.)

**LANARK**, (derived by some from *Lan-ærig*, the bank of the river, by others from the British *Llan-erch*, a green or glade;) a royal burgh of Scotland, the capital of Lanarkshire, situated on an elevated piece of ground near the banks of the Clyde, thirty-one miles west from Edinburgh, and twenty-five south-east from Glasgow. It is supposed to be the Colonia of Ptolemy, and is known to have been of considerable note at a very early period, Kenneth II. having held a parliament here in 978. In 1244 the town was destroyed by fire, and in 1297, the heroic Wallace first raised the standard of liberty here, slew the English governor, and made himself master of the place. It was erected into a royal burgh by Alexander I., and its charters were finally confirmed by Charles I. in 1632. The chief employment of the inhabitants is weaving for the Glasgow manufacturers. In the neighbourhood, higher up the Clyde, stand the cotton-mills and village of *New Lanark*, founded by David Dale in 1785, and celebrated as the earliest subject of Mr Owen's philanthropic exertions. Population in 1831, of the town of Lanark, 4,266; of New Lanark, 1,901; of the surrounding parish, 1,505; total, 7,672.

**LANARKSHIRE**; a large and important county of Scotland, bounded on the east by the shires of Edinburgh and Peebles, on the west by those of Ayr and Renfrew, on the north by those of Dumbarton, Stirling, and Linlithgow, and on the south by the county of Dumfries. Its greatest length from Queensberry-hill on the south, to near the eastern extremity of the burgh of Renfrew on the north-west, is fifty-two miles; and its greatest breadth, nearly in a line at right angles to its length, from the confines of Peebles-shire on the east at Garvald-foot, to the source of the Avon, on the frontiers of Ayrshire on the west, is thirty-three miles. It contains an area of 926 square miles, or 471,278 Scots statute acres. Towards the south, the county is hilly and mountainous. A ridge of lofty mountains, called the *Lowthers*, stretches through the country from near the Clyde to the south-western boundary, where part of the chain separates Lanarkshire from the county of Dumfries. From the southern extremity of Lanarkshire another ridge runs northward for many miles betwixt and Peebles-shire. A third chain, farther to the north, crosses the county towards the west, about twenty miles from the southern limit. The eastern part of this chain is called the hills of Tinto, and the western part, separated from the eastern by the vale of Douglas, the Haughshaw hills. The general surface of this hilly district is about 1000 feet above the level of the sea. Many of the mountains are of a great height; Lowther Hill is 2,450 feet above the same level; Tinto 2,236 feet; Coulter-fell about the same height; and Cairn-table, on the borders of Ayrshire, measures 1,650 feet. To the northward of the hills of Tinto, Lanarkshire is, in general, a fine champaign and variegated country, declining to the north-west, and in many situations remarkable for its picturesque beauty and the grandeur of its scenes. Many beautiful vales stretch amongst the numerous rivers. The chief of these is the vale of Clyde, extending from about two miles above Lanark, to within three or four miles of Glasgow, every where remarkable for its natural

beauties, its numerous country seats, its waterfalls, romantic dells, orchards, hanging woods, and cultivated fields.

The principal river of the county, and in point of commercial importance the first in Scotland, is the Clyde; which, traversing the whole length of Lanarkshire, gives it the name of Clydesdale. It collects its supplies from no less than 1200 square miles of surface, including the areas described by its tributary streams. Its farthest source is situated near Queensberry-hill, at the southern extremity of the county, at the head of a rivulet called the Crookburn, flowing into the river Daer, and which, after a course of several miles, is joined by a stream called Little Clyde; this last has its rise near the mountain of Clydeslaw, in the vicinity of which the rivers Tweed and Annan have also their sources. The general direction of the river is towards the north-west. In its course, by a noble sweep, it winds around the base of the mountain of Tinto; then leaving the hilly district of the county, and entering the more cultivated division, at no great distance from the southern extremity of the vale of Clyde, it forms the celebrated waterfalls of Bonnington, Corra, Dundaff, and Stonebyres, in the vicinity of the town of Lanark. Continuing to flow through this fine vale, it passes Hamilton, Rutherglen, and the city of Glasgow, a few miles above which it first receives the influence of the tide; and then gliding onwards with a smooth and gentle current, passing Renfrew, Dumbarton, and Port-Glasgow, it forms the Frith of Clyde, nearly opposite to Greenock.

The earlier history of Lanarkshire will be found comprehended in the article *Glasgow*, to which the reader is referred. It formed a portion of the Roman province of Valentia, and afterwards of the British kingdom of Strath-Clyde, until that kingdom, in the ninth century, became incorporated with those of the Scots and Picts. The county of Lanark formerly included what is now called Renfrewshire; but in the reign of Robert III. that portion of it was disjoined from Lanark, and formed into a separate jurisdiction, in favour of his eldest son James, prince and steward of Scotland, by a charter of erection, dated at Perth, 10th December, 1404. At that time Lanark was distinguished by two divisions or wards, called the *Over ward* and the *Nether ward* of Clydesdale; the burgh of Lanark being the chief town and seat of justice of the former division, and the burgh of Rutherglen of the latter. These divisions continued till the last century, when they were formed into three wards, namely, the upper ward, with Lanark for its chief town and seat of justice; the middle ward, with Hamilton, and the lower ward, with Glasgow. For each of these wards there is a sheriff-substitute appointed by the sheriff-depute of the shire.

Lanarkshire contains excellent freestone, limestone, ironstone, coal, and granite. The most valuable freestone is found in the lower part of the district, with which the buildings in the city of Glasgow, and the adjacent country, are constructed. Limestone is to be met with in many places, but principally in those parts of the country lying to the northward of the Tinto hills. In almost all the limestone rocks, are to be met with shells and other fossils, which are sometimes very numerous, and of many different species. Ironstone is very abundant in some situations. It lies in regular strata above the limestone and coal; in others in contact with sandstone; and in others again, it is to be met with in the form of balls, which are of an excellent quality, yielding upwards of 50 per cent. of iron. The ironstone found here, is entirely used in the different furnaces in the county, particularly at those of Clyde,

Calder, Cleland, and Shotts. The richest mines are those of Calderwood and Crossbasket, in the parishes of Kilbride, and which have been long wrought to great advantage. The most valuable metallic ores are, however, situated in the southern part of the county, where lead has been wrought for more than two centuries. The principal mines are at Leadhills. The veins of lead vary in width from a few inches to fifteen feet. Silver is extracted from the lead, in the proportion of six to twelve ounces in the ton. In the same district of the county, gold is also found amongst the mountains in veins of quartz, or washed down into the sands of rivulets. Gold was first discovered here in the reign of James III. by one Cornelius Devossec, a lapidary of London; and a considerable quantity of those pieces called *uncers*, coined from it. In the reign of James V. 300 men are said to have been employed searching for the precious metal for several summers, and to have collected gold to the amount of £100,000 sterling. Lapis lazuli, and antimony, have also been found in small quantities. A more valuable mineral than either of these, is, however, found here in abundance, viz. coal. It has been calculated, that the coal stretches through this county in one solid mass, over nearly 110 square miles, or 55,000 acres; and taking all the strata of coal into account, the thickness cannot be less than five yards.

In Lanarkshire a great variety of soils exist, but the moorish and mountainous predominate. Even many of the more genial soils are cold from their substrata, and damp from the climate. The husbandry of the county is chiefly distinguished for its orchards and its breed of horses. The Clydesdale orchards lie chiefly between the lowest fall of the river and the mouth of the South Calder. Most of them are planted on steep hanging banks, and nothing can exceed in beauty and luxuriance this portion of the county. They consist chiefly of apple, pear, and plum trees, and are valued at about £2000 annually. The draught horses of Clydesdale have been long held in high estimation, and are considered superior to any in England. They first began to be improved by crosses from Flanders about 1760. Dealers from all parts of the country come to the Glasgow and Rutherglen fairs to purchase them.

At an early period, the inhabitants appear to have been much engaged in the buying and selling of wool, and the manufacture of coarse woollen cloth. In the early half of the last century, a great deal of fine linen and checks was made, and large quantities of yarn spun by the hand. This led to the establishment of manufactures of lawns and cambrics, which have been succeeded by cotton goods. The extent to which the cotton manufacture is now carried on in Lanarkshire may be seen by a reference to the article *Glasgow*. Population of Lanarkshire in 1755, 51,791; in 1791, 126,354; in 1801, 150,690; in 1811, 192,087; in 1821, 244,766; in 1831, 316,819.

LANCASHIRE, the county palatine of Lancaster, is bounded on the north by Cumberland and Westmoreland, on the east by Yorkshire, on the south by Cheshire and the river Mersey, and on the west by the Irish Sea. Its extreme length is seventy-four miles, and its breadth varies from fifteen to twenty-four miles. Its surface, according to the trigonometrical survey, contains 1631 square miles, or 1,171,840 statute acres, of which 370,000 are in a state of tillage, 450,000 in pasture, and nearly 400,000 in moors, mosses, and woodlands. The county is divided into the six hundreds of Lonsdale, Amounderness, Blackburn, Leyland, Salford, and West Derby. It lies in the ecclesiastical province of York, and in the diocese of Chester, which was

separated from that of Litchfield by Henry VIII.; it is divided into the two archdeaconries of Richmond and Chester, and is included in the northern circuit.

Before the conquest of Britain by the Romans, that part of the county bordering on Yorkshire was inhabited probably by the Brigantes, while other parts were occupied by the tribes of the Voluntii and the Siatuntii; and, in the later ages of the Roman empire, Lancashire was included in the province called *Maxima Cæsariensis*. The remains of the Roman roads are still discernible in various parts of the county; the principal of these was, according to some authorities, the more northern portion of the Watling Street, and it extended from the Mersey in a northern direction, near Preston, Garstang, and Lancaster, to Carlisle. By the invasion of the Saxons, the province became a scene of bloodshed and confusion. The banks of the river Douglas witnessed, it is said, four successful battles of the renowned British prince Arthur against these intruders. The Saxons established their kingdom of Deiri, which included Lancashire, about the year 547, under Ella. Forty years after, Aðelfrid, the king of Bernicia, the county seated between the Roman walls, having married Acca, the daughter of Ella, king of Deiri, expelled her infant brother Edwin from the throne, and united the two provinces into the kingdom of Northumberland. A short time after, however, he was dispossessed by Edwin, who was one of the most powerful princes of the heptarchy, and who, becoming a convert to Christianity, introduced the new faith into his dominions. Northumberland was united to the rest of the kingdoms of the heptarchy under Egbert in the year 827: it partook of its full share of suffering from the piratical Danes, and at the conquest fell under the iron yoke of William the Norman. The period when Lancashire was first formed into a county, and when the boundaries of its parishes were marked, cannot be ascertained with any precision. In the survey of Domesday book, Lancashire is not described under its proper title, but the two hundreds north of the Ribble are included in Yorkshire, and the country between the Ribble and Mersey is inserted under Cheshire. This latter portion was held by Edward the Confessor, and the chief of the northern part by Earl Tosti; nearly the whole of the county was bestowed by the conqueror on Roger of Poitou, who afterwards forfeited these immense possessions. The generality of topographers, following Camden's authority, have stated that the county was first made palatinate, with *jura regalia*, as fully enjoyed by the earl of Chester, by a patent to John of Gaunt, when created duke of Lancaster; but it is certain, from the patent rolls in the tower, that these privileges were conferred by a grant to the duke of Lancaster, father-in-law to John of Gaunt, in the 25th of Edward III. The extent of the duchy must not be confounded with the limits of the county, the former anciently comprising vast estates lying in various parts of the kingdom, the appanage of the duke, possessing its own courts, and governed by its own officers. Lancashire was distinguished in the sixteenth and seventeenth centuries by the prevalence of popular superstitions relative to witchcraft. In 1594, Ferdinand, earl of Derby, died, probably from the effect of poison, and his death and previous sufferings were attributed by himself and his attendants to magic and sorcery; in 1612, nineteen poor women were arraigned and tried as notorious witches at the summer assizes at Lancaster; and, in 1633, other persons were accused, in consequence of which an investigation took place before the king and his physicians, when the discrepancies in the evidence of the witnesses occasioned the acquittal of the prisoners. The national delusion on this subject, however, long

survived this period, though it has now happily disappeared before the progress of knowledge; and the phrase of "Lancashire witches" has of late years been applied by way of compliment to the females of this county on account of their personal charms. During the great civil war, Lancashire was the seat of various skirmishes, sieges, and battles, particularly that of Preston, 1648, in which Cromwell defeated the duke of Hamilton, who had intended to penetrate into England, and deliver the captive monarch. In the rebellion of 1715, Lancashire was again the seat of war, though the inhabitants were in general well affected to the house of Hanover. In 1745, the young chevalier passed through the county in his way to the south, but in a few weeks returned with some precipitation. Henceforward the most striking point in the history of Lancashire is the astonishing increase of its commerce and manufactures, as detailed in the description of the various towns in which they have been established.

The outline of the county of Lancaster is extremely irregular; it is divided from Yorkshire and Westmoreland by moors, mountains, and rivers, and on the west side the coast is indented by bays and harbours. There is a great variety of soil and surface, but in general it is not well adapted for cultivation; hence the ancient thinness of its population, shown by the comparatively small number of parishes into which it is divided. The northern detached part, commonly called the hundred of Furness, but belonging to that of Lonsdale, partakes of the romantic character of the neighbouring district of the lakes. It is a wild and rugged region, abounding in iron-ore and slate, and covered with groves of underwood, successively cut down and converted into charcoal for the supply of the iron furnaces. The county includes some mountain heights of considerable elevation, among which the most remarkable are Pendle Hill, two miles east of Clithero, according to the trigonometrical survey of England, 1803 feet above the level of the sea; Rivington Hill, near Bolton, 1545 feet; Wittle Hill, 1614 feet; and Conistone Fell, in Furness, 2577 feet. The more southern part of the county may be regarded as consisting of two unequal portions; the smaller one extending between the borders of Westmoreland and the Ribble, and the larger including the country between that river and the Mersey. Lancashire is watered by numerous rivers, of which the following are navigable:—the Mersey, the Ribble, the Lion, or Lune, the Irwell, the Douglas, the Wyre, the Ken, the Leven, the Dudden, and the Crake. The principal lakes are, Winandermere, between this county and Westmoreland; Conistone-mere, in the centre of the Fells of Furness; and Eastwaite Water, situated between the two preceding. Lancashire is not only furnished with navigable rivers, but also intersected by numerous canals. (See *Canals*.) The soil in the northern part of the county or hundred of Lonsdale, is less productive than elsewhere, being chiefly sands or marsh land; further south, about Garstang, the country is famous for a fine large breed of horned cattle; and the tract between the road from hence to Preston and the sea, called Fylde or Field, is level land, producing a large quantity of oats. The parts eastward of this district, comprising the old forests of Wyredale and Bowland, are mountainous, and generally barren. In the southern parts of the county, on the banks of the Tame and Irwell, are rich and fertile meadows; and in the neighbourhood of Manchester and other manufacturing towns, the land is highly cultivated. Lancashire is noted in the annals of gardening as having furnished the first potatoes which were raised in England; and what are called fancy flowers, especially the auricula, are here cultivated more generally than in any other

part of the country, except near the metropolis. The climate of Lancashire is humid, although, from the absence of fogs and stagnant waters, it is not unhealthy. The most important mineral products are coal, copper, lead, and iron. The great coal tract commences on the south of Prescot, and crossing the country in a north-easterly direction, passes into Yorkshire; but coal is likewise found in abundance near Manchester, and northwards beyond Lancaster. Cannel coal is met with near Wigan, and at other places, and sometimes in contact with the black coal, or slightly mixed with it, as at the pits near Layton Hall. Copper ore occurs in the rough barren mountains, towards the northern extremity of the High Furness or Fell district, and especially at Coniston, Muckle Gill, and Harttriggs; but it has not been discovered to the south of Lancaster sands in quantities sufficient to bear working with advantage. Lead ore is chiefly met with in the northern and north-eastern parts of the county, but it is by no means abundant. At Anglezark, near Chorley, is a lead mine, the ore of which, galena, is intermixed with carbonate of barytes. Iron ore is the principal product of the district of Furness; and though found in some other parts of the county, it is there only sufficiently plentiful to render the working of it profitable.

Lancashire is distinguished as the ground sent of the cotton manufacture; a full account of the rise and progress of which will be found in the article *Cotton Manufacture*. (See also the articles *Manchester* and *Liverpool*.) Fabrics of silk, wool, and linen, as well as cotton, are largely manufactured in this county, and here are carried on hat-making, calico-printing, bleaching, dyeing, machine-making, iron-founding, and the manufacture of paper, glass, and earthenware. Steam-carriages were also here first brought to perfection, and experiments with them on a large scale were first made on the rail-road between Liverpool and Manchester. Before Lancashire became a manufacturing county, its population was small. In the year 1700, it amounted to only 166,200; in 1750, it had increased to 297,400; in 1801, to 695,100; in 1811, to 828,300; in 1821, to 1,052,859; and in 1831 to 1,336,854.

LANCASTER, the county town of Lancashire, is situated within the hundred of Lonsdale South, on the bank of the river Lune or Lune, distant from London 239 miles N. N. W. Lancaster was a Roman station, as may be concluded from its commanding situation, the numerous relics here discovered, and its termination, *castræ*, which appellation was seldom given by the Saxons except to such places as had been occupied by the Romans. During the Anglo-Saxon rule, the history of Lancaster is exceedingly obscure. It may be supposed that it was considered of more importance than any other town of the district, from its giving name to the county; though it must be acknowledged that, in Doomsday Book, Lancaster is considered merely as a ville belonging to the manor of Halton, and consequently must have fallen to decay. At the period of the survey it had returned to the possession of William the Conqueror, from the defection of Roger of Poitou, to whom it had been originally given. The honour of Lancaster was restored to this baron by William Rufus, in whose reign the castle and the church were founded; but by his subsequent defection, under Henry I., he lost these vast possessions, which became afterwards the appanage of various nobles of different family, till they were finally conferred on the blood royal in the person of Edmund Crouchback, in 1266, by his father Henry III., with the title of earl of Lancaster. This prince left two sons, of whom the elder, Thomas, taking arms against Edward II., was defeated at Borough Bridge, and beheaded at Pontefract; but, his

attainder being reversed, the title descended to his brother Henry, who was succeeded in 1345 by his son Henry, the popular earl of Derby in the French wars of Edward III., and advanced by that monarch to the dukedom of Lancaster in 1351, with the same jura regalia as the earls palatine of Chester had ever enjoyed. His daughter Blanche marrying John of Gaunt, that prince, at the death of his father-in-law, was created by Edward III. duke of Lancaster. The duchy became consequently, a petty kingdom, and some of its original regulations are yet in force: it was vested by due succession in Henry IV., son of John of Gaunt, and in the crown it has ever since remained, but under the separate government of its own law officers, distinct from those of the nation at large. In the year 1322 Lancaster was entirely devastated by the Scots under Robert Bruce, and the castle itself was somewhat injured. This magnificent and celebrated structure is now used as the county prison. Placed on an elevation at a small distance from the Lune, it was admirably calculated to keep in check the enemies from the north. Its space embraces an area of 380 feet by 350, and it is supposed to be capable of containing 5000 men. The walls of this structure are of prodigious thickness, and its apartments of spacious dimensions: it is supposed to have been the work of Roger of Poitou. The gate-way was built by John of Gaunt; it consists of two semicircular towers, each surmounted by an octangular turret, and defended by a triple row of machicolations; in a niche, over the gate, is a modern statue of their founder. The castle presents a stately and threatening aspect: the walls were strengthened by round towers, which have been so far repaired as scarcely to be distinguished from the very extensive modern additions, which, at a certain distance only, from the sharpness of the new masonry, combine harmoniously with the original building. Within the area are the shire-hall, and the various appendages of the courts of justice. The castle has been used as the county prison since the age of Elizabeth. In one of the circular towers, called John of Gaunt's oven, is a collection of rolls, that is to say records, relating to the county. To the west, part of an ancient moat, formed by John of Gaunt, yet remains. A terrace surrounding more than half the castle affords a delightful promenade, presenting a view of the windings of the Lune, till it loses itself in the bay of Morecambe. On the whole, no county in England can boast of a gaol with all its concomitant parts so complete and grand as that of Lancaster. St Mary's church, situated at a small distance from the castle, is supposed to have been likewise founded by Roger de Poitou; it seems to have been rebuilt in the fifteenth century. The two subordinate chapels of St John's and St Anne's, in the town, present nothing remarkable. The Roman Catholics have a chapel here, and in Lancaster are several meeting-houses and chapels, for the usual classes of the dissenters, to which are attached various schools and charities. Among the public buildings are the town-hall, the custom-house, with a handsome portico of four Ionic columns, a theatre, the assembly rooms, and a bridge of five elliptical arches erected in 1785 by Mr Harrison of Chester. A little below are some remains of the old bridge; a mile higher up the river is the celebrated bridge aqueduct of the Lancaster canal. The county lunatic asylum is a quadrangular building, and is esteemed a model for similar institutions. The commerce of Lancaster, particularly the former West India trade, is now inconsiderable. A noble series of warehouses on the quay is nearly unoccupied. The Lune is navigable to Lancaster only for vessels below 250 tons, and the deserted port presents a striking contrast to the bustle and activity of Liverpool. Ex-

cellent ships are built at Lancaster, and it is celebrated for its cabinet work. The manufactures consist of cordage, sail-cloth, some cotton and worsted yarn, and candles. The town receives a considerable influx of company at the assizes held twice a year; also at the elections for knights of the shire, and at the annual races; and here are held the quarter sessions, with some other local courts of inferior jurisdiction. The parish of Lancaster is extensive, and contains several remote townships entirely isolated and disjoined from the body of the parish: population of borough in 1831, 12,613; of parish, 22,294.

LANCE; a weapon consisting of a long shaft, with a sharp point, much used, particularly before the invention of fire arms. It was common among the Greeks and Romans. The Macedonian phalanx was armed with it, and it was the chief weapon of the Roman infantry. The javelin, or *pilum*, was but secondary. The lance is found among almost all civilized tribes: it was the chief weapon in the middle ages, and is now considered one of the most effective arms of cavalry. The lance of the knight, in the middle ages, was of a peculiar form. Near the lower end, it was very thick, with a deep opening, in which the arm was placed when the lance was put in rest, preparatory to a charge. Immediately in front of the opening, the lance was from one to one and a half feet in diameter, and sloped off towards the upper end, which was from one half to three-fourths of an inch in diameter. From this weapon the small bands, of which the cavalry of the middle ages consisted, took their name. A lance denoted a man at arms (horseman completely armed) with four or five attendants. Among the French, in the fifteenth century, these attendants consisted of three archers, one *coutillier* (so named from the long, broad dirk in his belt), and one page or valet. The introduction of fire-arms gradually led to the disuse of the lance in the West of Europe, though it continued among the Turks, Albanians, Tartars, Cossacks, Poles, and Russians, and other Slavonic tribes, among whom it was borne by light-armed cavalry, on fleet horses. Frederic the Great, seeing the advantageous use made of this weapon by the Poles, gave it to a portion of his cavalry, and afterwards formed an entire regiment of lancers. The Austrians followed, and soon established three regiments of *Uhans*, as they were termed. After the partition of Poland, many Poles entered the French service, and a body of Polish lancers was established. The war with Russia, in which the efficiency of the lance in the hands of the Cossacks, particularly in 1812, was strikingly manifested, brought this weapon into still more repute, and the Prussians formed three regiments of *Uhans*. The French lancers were formed in 1813, to cope with the Cossacks. Almost all the armies of Europe now have regiments of lancers. To use the lance with effect, however, requires much practice. The lances now in use, among the European cavalry, have a shaft of ash or beech wood, eight, twelve, or even sixteen feet long, with a steel point, eight or ten inches long, and, to prevent this being bawn off, the shaft is guarded by two strips of iron, one and a half to two feet long, below which an iron ball is sometimes placed to prevent the lance point from penetrating too far. The other end has an iron cap, to prevent its splitting. The point has a small flag, intended, by its waving, to frighten the horses of the enemy. When not in use, the lance is carried in a leathern shoe, by the right stirrup, dependent by a leathern thong on the right arm. In use, it is carried under the right arm. This weapon requires a practised horseman. See *Pike*.

LANCELOT OF THE LAKE; the name of one of the paladins celebrated in the traditions and fa-

bles relating to king Arthur (q. v.), or the Round Table. According to tradition, Lancelot was the son of Ban, king of Brucic, and, after his father's death, was educated by the fairy Viviana (the Lady of the Lake). The youth having given proofs of great valour, she took him to Cramalat, to the court of king Arthur, and requested him to make him one of his knights, and to admit him to the number of the heroes of the Round Table. Arthur, with his sword (*escalibor*), dubbed him knight, and Lancelot subsequently distinguished himself by his extraordinary deeds and great heroism amongst all the paladins of the Round Table. His love for Genevra, the beautiful wife of Arthur, and his disregard of Morgana, a fairy, and the sister of Arthur, placed the knight in the most dangerous and marvellous situations, from which, however, he always extricated himself by his valour and the assistance of the Lady of the Lake. He finally succeeded to the throne of his ancestors, after having defeated king Claudas, the murderer of his father, but was slain by Mordrec, the nephew and murderer of Arthur, whom Lancelot wished to punish. In his last moments, Viviana appeared to him, and, with a gentle kiss, took the last breath from the lips of the dying hero, who was the sole survivor of the knights of the Round Table. His remains were taken to his castle, and there deposited near those of the beautiful Genevra. This tradition has been variously handled by poets.

LANCEROTTA; one of the Canary islands. See *Canaries*.

LAND, PROPERTY IN. The relations of landed property are among the most complicated and most important in civil society. They lie at the foundation of almost all the relations and institutions of the state. On their right direction depend the strength and vigour of the commonwealth. They mark the transitions from one step of refinement to another (hunting and fishing, raising of cattle, agriculture conducted by slaves and bondmen, or by freemen, with or without a right in the soil). These relations express the ancient hostility between various classes of people, between hunters, herdsmen, and husbandmen, between city and village, &c. Nevertheless, hardly any subject of law and politics has been investigated with so little profoundness. In no one has prejudice gained such an ascendancy, and resulted in such important consequences. Almost all modern constitutions have taken landed property for the basis of their most important institutions, and given the owners of land a power over the other members of society, the consequences of which are apparent. Distinguished writers have even gone so far as to call owners of land the only true citizens—the nation, properly so called; and all others who chance to have no immediate share in the soil of the state where they reside, are styled by them mere strangers—tenants at will—a homeless rabble, dependent on the good pleasure of their landlords—a class of people, who, in affairs of common interest, are scarcely permitted to hear, and never to speak; whose duty is obedience to their natural masters, the proprietors of the land. But, if these relations are carefully examined, this view is found to be connected with palpable errors.

1. It is wrong to suppose that the banding together of men in a state is connected inseparably with the appropriation of landed property, and that this constitutes the distinction between wandering hordes and civil society. Even nomadic nations have some general idea of the exclusive right of their descendants to the lands which they have been in the habit of periodically occupying, and where they have found support for themselves and their cattle. They esteem it an attack upon their essential rights, for

another family or tribe to usurp these pastures, just as hunters consider it a violation of their privileges, when their hunting grounds are contracted by the encroachment of settlers, or by the incursions of strangers in pursuit of game. Hence Abraham separated from Lot. (*Genesis*, xlii.) The various treaties of the European settlers with the savages of the American wilds clearly show how deeply the idea of the rights of tribes and families in the soil is rooted in nature, and how fully it is developed long before the rude inhabitants have united under a regular government.

2. The division of territory among private owners takes place much later, is not inseparably connected with the purposes of a state, and is incapable, at any time, of absolute perfection. We must remember, on the one hand, that a division of this nature takes place before the idea of the true purposes of a state is matured; and, on the other, experience shows, that even a very regularly constituted state may exist in connexion with the original community of property in the soil. But the assertion of the right of private property in the soil, before the assemblage of men, for common purposes, has given rise to states, is so rare, that perhaps history offers no precedent of it, except in the case of some Robinson Crusoe, who has claimed the ownership of some unappropriated territory on which chance had thrown him, and, what is more to the purpose, a proper ownership in the soil can arise only in and for the purposes of a state; and this right is always different from that which obtains in regard to movable property. The confusion of these two relations, in law so essentially different, arises from the circumstance that the same name is applied to both, and is the source of those numerous errors, the evil consequences of which are felt in every vein of the body politic.

3. Kant has particularly shown that genuine property (and a possession not dependent on actual occupation, with all the consequences that result from it) arises first in and by the state. Before him, men were led away, by the customary ideas of positive law, to regard the occupation of property as an act by which an object of nature becomes, once for all, united with the person of the possessor, in such a manner that every other person must abstain from the use of it, even though the owner should leave it unemployed (if it be a piece of land wholly uncultivated), or be without the ability suitably to use it (as if it includes a large district). But there is no reason, aside from the positive law of the land, why one man should be authorized to bind for ever the will of others; and it is impossible in regard to the soil, because, in this way, it would be made for ever dependent upon the will of the first possessor, and others might be excluded from the very means of existence. Hence private property in land is among the institutions which are first established by the state; but it must be observed, that these still remain subject to alteration whenever the good of the state seems to require it. Apart from the state, a man has no unalienable property but his own person, and a claim upon others for a regard to his personal dignity, which arises from the worth of his nature, and makes it unlawful for others to use him merely as the instrument of their own purposes, or to avail themselves of his powers, or the fruits of them, against his will. Labour is therefore the foundation of property, apart from the institutions of the state; and its visible sign, that is, the alteration of form produced by it, gives notice to others that they are to abstain from the use of the article thus appropriated. By labour a man connects a part of himself with a given subject; but this relation is not eternal; it continues only while the form impressed on it by such owner remains; for the labour bestowed

by men on natural materials is only an alteration of the relations of form and place; it leads to no new product. Man can create nothing new. This privilege nature has reserved to herself by eternal and unchangeable laws; but man can only alter the forms and relations of natural productions, and bring them into connections in which the creative power of nature shall become serviceable to his ends. He impresses upon things the stamp of his own ingenuity, and exercises that dominion of mind over matter, the extension of which is an important part of his destiny. There is therefore a kind of property independent of that given by the institutions of the state, but not unalienable. As a man possesses nothing in nature, but the labour which he incorporates with it, that is, the form which he gives it, this right ceases when the effects of the labour are lost, and the form vanishes. Nature has a tendency to efface the impressions of art: the human form loses its symmetry, the tamed beast returns to his native wildness, and the cultivated field to its former sterility. The effects of labour are lost; and if a second now appropriates the object, when it is relinquished by the first, he deprives one of the fruits of his labour, and there is no question of property.

4. This view of the subject shows that the state is not to be looked upon as a combination of landed proprietors; for they have become landed proprietors only by means of the state itself; and it is just as absurd to derive the existence of the state from something that received existence from it, as to consider nobility older than sovereignty, and independent of it. It is likewise unfounded in an historical point of view. In the history of all states, we return with the fullest certainty, to the period when the soil was common to all the inhabitants, and to the subsequent period, when it was regarded as the rightful possession of a certain family or community. The family occupation is obviously the oldest form of restricted possession, which unfolded itself first in the patriarchal government, and is to be seen in the original constitution of almost every state. The origin of family property can be traced only to the immediate gift of a higher power. Thus Jehovah promised to the family of Abraham the land lying on the banks of the Jordan; and the North American tribes ascribe the right of the red men to their hunting grounds to a special gift of the Great Spirit. Hence we see the reason why, in all the early divisions of territory, some important portion of the land, or a permanent tax, as the tenth of all the fruits, was preserved for the service of the national deities. From common property there arose, under the patriarchal dominion, the exclusive right of the founder of the family: first, while the oldest member is the representative of the whole, it belongs to him to divide the common soil among the different members. If the population increases, and circumstances prevent the sending out of colonies, or the wandering of a part of the family, nothing remains but to procure from the ground a richer supply of provisions by regular cultivation; and, when the wandering tribes, who before subsisted by hunting, submit to the more arduous labours of agriculture, a division of the territory into portions, which are secured to individuals by conditions more or less settled, cannot be avoided. But the farms under which this important change takes place are almost infinite. Sometimes the land is divided among individuals every year; sometimes it is assigned to the principal members of the stock, the elders of the tribe, and by them subdivided among the inferior members. This is seldom done, however, without a compensation. The compensation, for the most part, consists of a certain part of the productions of the soil, or of a sum of money, fixed without requir-

to the harvest. The idea of common property gradually died away, especially when private property grew up in particular cases, or in neighbouring tribes, along with the annual division; and the head of the tribe, instead of remaining the manager of the common property, became its exclusive possessor. This has been the state of things in most of the countries in the south of Asia; and we find traces of it till a very late period, even in Europe, in which a patriarchal government, but slightly modified by the general constitution of the country, has obtained, till modern times, in the Scottish Highlands. Every tribe there viewed itself as a family, and the eldest member, or laird, as the master. The territory of the clan was his; what was not retained for his own use, or the public, he divided in large portions among his nearer relations (tacksmen), who either cultivated it themselves, or distributed it in smaller portions among the people. But the grant to the tacksmen was only transient: when the family increased in numbers, they were forced to give place to the nearer relations of the laird. (See *Highlands*.) The condition of common property in the soil is very different, when the family union gives place to a regular community; and this is a general consequence, wherever a part of the race seek new habitations on account of their increasing numbers, and where, to overcome the opposition of the primitive settlers, collections of emigrants from several families enter into a political union. In the constitution of communities, the property of the whole belongs to the associates collectively (and commonly a portion to the divinities of the country and the head of the society); and on account of the military constitution of most early communities, which are constantly in a state of defence or of aggression, they are obliged to take measures that there shall always be a competent number of able-bodied warriors, and also that no one shall be suffered to accumulate too much by purchase or inheritance. Hence a number of lots are laid out, each sufficient to support a family of freemen, and laws are enacted to restrain the further division, as well as the amalgamation of the divisions previously made. This was the case particularly in Sparta, but the plan failed. In Rome, before the laws of the twelve tables, there was a similar institution, and the consequence was, that the lot of a Roman, or his family property, could not be taken from him, or sold by him to another. As Rome retained many relics of the patriarchal government, and these had an important influence upon all their civil institutions, it was impossible for the relations of landed property to be free from it. The community in general had a large landed property, which was daily increased by successful wars (the conquered being usually deprived of a part of their territory); but the ruling patrician families were the only real gainers by the addition. The soil was divided among them; and, in fact, it would have been of little use to that class of citizens who subsisted on the income of their original lot, because men were wanting for the purposes of agriculture. This want of labourers is shown by the fact, that the patricians forced a vast number of their plebeian debtors to labour for them; and these debtors were numerous; for the constant wars that harassed the Roman government reduced multitudes to the necessity of borrowing. Hence it was much for the advantage of this class of people that, in the twelve tables, in the famous passage which gave occasion for dispute even in the time of the Antonines, and which has been understood as referring to the division of the debtor's body, provision was made, in all probability, for the divisibility and alienability of the landed property of the citizens. At the same time, it is manifest, that the desire of

the plebeians to establish a new and more just division of land (by the agrarian laws), was founded on the principles of right. But after this important step was once taken, a more and more perfect freedom and divisibility of landed property found place in the Roman law, which forms a characteristic trait of their legislation. In the German states, the dissolution of the ancient family unions by the institution of societies, was the fundamental principle which manifested itself first in the relation of leaders and their personal retainers. In the new states established by successive conquests, extremely complicated relations grew up; as the ancient inhabitants were sometimes deprived of all their landed property, as in England, for example, and sometimes surrendered only a part of it, as in Italy and the south of France; and this division also took place with many diversities of form. In regard to the share in the land which belonged to the conqueror, we find again a general division: a certain portion of the whole fell to the chief, who had to apply it to the support of his immediate attendants; another portion was assigned to the attendants themselves, and, after certain subdivisions and tithings, it was given up to the community as common property. This common property was enjoyed, not unrestrictedly, but on condition of appearing to do military service. In a few instances, it long retained its character of common property. It was sometimes divided among the people by the head of the community for cultivation; and here and there was bestowed on individuals, on condition of military service. This peculiarity is the foundation of the indivisibility of land, which occurs in some constitutions, and the exclusion of females from the right of inheritance (in the *terra Salica* of the Franks.) To this community of property, or allodial possessions (in Saxon, *folkland*, or *reeveland*), are opposed the infeudments of princes, which were often the means employed by them to collect from the mass of the people, whether conquerors or conquered, a new retinue of more faithful personal attendants (Latin, *fideles*; Spanish, *hidalgos*), to whom they gave these lands in pay, instead of money. Hence arose the *thaneland*, and the more extensive grants by written contract, the *bookland* of the Saxons, the *feh-od* (land paid for services, instead of money, from the Gothic *faiha*, cattle, wealth, money, reward; hence the English *fee*), or feudal possessions. The intermixtures, substitutions, and modifications, which these relations subsequently underwent, it is not necessary for us to dwell upon. We need only show how, in the modern states of Europe, private property in the soil may be traced to common property, and the clear evidence which it bears of such an origin, in order to prove that it depends upon a grant on the part of the community, and that hence the owners of landed property have no right in the soil, but what is permitted by the state. What they receive from the state is not an acknowledgment and confirmation of a right, which they before possessed independently of such acknowledgment, but the right itself. It is no arbitrary right, but it stands in close connexion with certain duties, and its existence and continuance are subject to the state legislation. The owners of landed property do not constitute the people, but only a single class, bound, like the rest, to devote their all to the promotion of the public good.

5. History goes hand in hand with philosophy thus far: while the former contradicts the supposition that landed property is perfectly unrestricted, to be used at will, the latter rejects the idea of such a grant as illegal, and even void. These philosophical grounds, indeed, must not destroy any actually existing rights; but reason has no small voice in deciding

what is actually contained in the existing rights. To sound reason it is evident, that every person must be allowed some resting-place on the earth; hence, as long as any place is left capable of affording support to another individual, the proprietors cannot arbitrarily deprive a fellow being of that support. They are bound to use the soil in such a way as to promote the general good. For every right has some duty for its basis; and landed property is possessed of peculiar rights, only because it is pledged to furnish men with food. This duty becomes more important and pressing as the population increases; hence it is necessary for the state to attend the more carefully to the fulfilment of it; and the more sacred becomes the duty of those in whose hands the means are lodged. According to these premises, the states of Europe have regulated their conduct; they have not suffered ground capable of yielding income to lie unimproved; they have judiciously limited the cultivation of such plants as contribute nothing to the nourishment of the human species, as tobacco, for example; they have encouraged the cultivation of other plants; they have forbidden the exportation of articles which are needed in the state where they are raised; and, in some instances, their seal has led them into wrong principles in their commercial intercourse; above all, they have taken away all obstructions to the improved cultivation of the land. And these ordinances are imperiously demanded by the state of society; for the right of property in the soil has no other end than to promote the cultivation of it for the general good; and it is on such conditions only that the state has distributed the land among individuals. If it is found necessary to deprive a proprietor of landed property of any advantage accruing to him from such a possession, it is not maintained that he shall receive no compensation; but if a compensation is granted, the laws cannot be charged with interfering with his rights, if they impose restrictions upon him in the use of his ground. Hence the common good allows the state to repeal all laws which are a restraint upon the free use of the soil, as tithes; to promote its distribution by breaking up entails, &c., and to secure the cultivator, by not permitting him to be driven from the soil at the will of the landlord, or even by making temporary relations permanent; as the landed proprietors in Ireland, for example, were forced to substitute, in part, quit-rents in the room of leases for years. These ordinances concern the whole community; so that persons who are destitute of landed property have as good a right to be heard on this subject as the landed proprietors. Hence,

6. It is matter of serious reflection, that the constitutions of many modern states provide that the representative body shall be composed entirely of landed proprietors. This rests partly on usage, partly on principles intrinsically good, that men receive the greatest advantage, not from a hasty renunciation of ancient laws, although imperfect, but from slow and cautious advancement, and that it is far more necessary to preserve the existing institutions, and to build them up with judgment and care, than to think of rearing new edifices; for though the foundations of these may seem perfect, their advantages are not certain. But whether this end can be attained by an exclusive representation of landed proprietors, may well be made a question. How can the true wants of all classes be made manifest, if the representation be confined to one? For this reason, a variety in the condition and rank of representatives is highly desirable; and, in some representative governments, provision has been made to attain such an object. Necessary as it is to provide that the representatives shall consist of men interested in

preserving, and not in destroying, the settled order of things, it is equally necessary to avoid, as much as possible, the preponderance of men interested in maintaining old abuses, and to provide, as fully as possible, for representing the views of the great body of the people. It is not the soil, nor its possession, but the great interests of the whole community, which form the object of the state and of representative constitutions.

LAND, in the sea language, makes part of several compound terms: thus *laying the land* denotes that motion of a ship which increases its distance from the coast, so as to make it appear lower or smaller on account of the intermediate convexity of the sea.—*Raising the land* is produced by the motion of the vessel towards it.—*Land is shut in*, signifies that another part of land hinders the sight of that the ship came from. *Land to*; or so far from shore that it can only be just discerned.—*Land turns*; a wave that, in almost all hot countries, blows at certain times from the shore in the night.—*To set the land* that is, to see by the compass how it bears.—*Land breeze*; a current of air which, in many parts within the tropics, particularly in the West Indies, regularly sets from the land towards the sea during the night, and this even on opposite points of the coast.—*Land locked* is said of a harbour which is surrounded by land on all sides, so as to exclude the prospect of the sea, unless over some intervening land.—*To make the land*, is to discover it after having been out of sight of it for some time.—*Land-mark*; any mountain, rock, steeple, or the like, near the sea-coast, which serves to direct ships passing by how to steer, so as to avoid certain dangers, rocks, shoals, whirlpools, &c.

LANDS, PUBLIC. See *Public Lands*.

LANDAMMANN, in Switzerland (originally *Landammann*); the highest magistrate in the country contradistinguished from *Stadtmann*, the highest magistrate in the city. At present, the highest magistrate in the cantons of Uri, Schwyz, Unterwalden, Glarus, Zug, Appenzell, St Gall, Thurgau, Tessin, and Pays-de-Vaud, is called *Landammann*. Most cantons have two or more, who command alternately; some only one. The first magistrates of the other cantons are called *Schalthies* (mayor), *Burgmeister*, *Landhauptmann*, *Syndicus*, &c. The president of the diet of all Switzerland is also called *Landammann*.

LANDAU; a district of 530 square miles, with 101,600 inhabitants, and a fortified town of the Germanic confederacy, with 5700 inhabitants; lon. 10° E.; lat. 49° 13' N. It is under the sovereignty of Bavaria; was formerly a free imperial city, belonging to Lower Alsace. Vauban constructed the fortifications.

LANDECK; a town in Silesia, near which are some mineral springs. The waters contain sulphur of potash, lime, and nitrogen. The temperature is 86° Fah.

LANDER, RICHARD; the discoverer of the course of the Niger, was at first the servant of captain Clapperton, whom he accompanied on his second expedition into the interior of Africa. He came from the Bight of Benin with his master, after whose death at Soccatoo (April 13, 1827), he returned to the coast. His journal is published with Clapperton's. (See *Clapperton*.) In the spring of 1833, he set out with his brother John, on an exploring expedition, and was landed at Badagry, March 23, where he intended to proceed to lake Tchad. He died on the 2d February, 1834, at Fernando Po, of wounds received from the natives. The British government granted a pension of £70 a-year to his widow and of £50 a-year to his infant daughter. See *Niger*.

LANDES; a department in the south-west of France. See *Department*.

LANDINUS, CHRISTOPHER, an Italian scholar, philosopher, and poet, born at Florence in 1424, was patronized by Pietro de' Medici, and appointed tutor to his son, the afterwards celebrated Lorenzo, with whom an attachment highly honourable to both parties took place. Landinus, in his old age, became secretary to the seignior of Florence, and died in 1504. He left several Latin poems, and his notes on Virgil, Horace, and Dante are much esteemed. His philosophical opinions appear in his *Disputationes Camaldulenses* (1480, folio, and Strasburg, 1508).

LANDO, MICHEL; a wool-comber at Florence, who became, during the revolution of that republic, in 1378, *gonfaloniere* of the republic. Machiavelli, in the third book of his History of Florence, describes him as one of the wisest and greatest men, though from the lowest class. By his prudence and firmness, he put an end to disorder, deposed the existing magistrates, created a new nobility, and divided the people into three classes. This state of things, however, only lasted until 1381. (See Machiavelli's *History of Florence*.)

LANDRECIES, or LANDRECY; a fortress on the Sambre (navigable from this place), in the department Du Nord; lon. 3° 42' E.; lat. 50° 22' N.; with 3800 inhabitants. Its situation renders Landrecy important in any war between Germany and France. Francis I. captured it, but it was recovered by Charles V. In 1655, it was taken by Louis XIV., and was ceded to France by the peace of the Pyrenees, in 1659. In 1712, prince Eugene besieged it; but Marshal Villars delivered it. In 1794, Landrecy was taken by the Austrians, after a valiant defence, but recovered the same year. In 1815, the Prussians captured it after a short bombardment.

LANDSCAPE PAINTING. See *Painting*.

LAND'S END, in Cornwall; the western extremity of England. Lon. 5° 45' W.; lat. 50° 6' N.

LANDSHUT; a city in the Bavarian circle of the Iser, with 8000 inhabitants on the river Iser; lon. 12° 6' E.; lat. 48° 30' N. The city is well built; the spire of St Martin's church is 456 feet high. Landshut formerly contained the university called *Ludovico-Maximiliana*, which was transferred hither from Ingolstadt; but, in 1826, it was transferred to Munich. (q. v.)

LANDSHUT, in Silesia, government of Leignitz, at the foot of the Riesengebirge, on the Bober (3100 inhabitants), is important for its linen trade.

LANDSMANNSCHAFT. See *University*.

LANDSTURM. See *Levée-en-Masse*.

LANDWEHR. See *Militia*.

LANFRANC, a prelate of the eleventh century, distinguished by his learning and abilities, as well as by his opposition to Rome, was born in 1005, at Pavia, and, after having been for some time a professor of jurisprudence at Avranches, assumed the cowl, and was elected prior of the abbey of Bec in 1044. In 1059, he entered into a dispute with Berengarius of Tours, at Rome, respecting the doctrine of transubstantiation, and maintained the controversy against him, not only personally before the general council held in that city, but subsequently in his writings. Three years after, he exchanged his priory for the abbey of St Stephen, at Caen, in Normandy; and when William, the sovereign of that duchy, acquired the English throne by conquest, the interest of that prince procured his election, in 1070, to the archbishopric of Canterbury, then become vacant by the deposition of Stigand. In his superintendence of this diocese, he was early involved in a contest with Thomas, archbishop of York, respecting the primacy, which was decided in his favour.

Lanfranc was an able politician, as well as a munificent prelate. He died in 1089. His writings were printed in one volume, folio, 1647.

LANGDON, JOHN, an eminent American patriot, was born at Portsmouth, N. H., in the year 1739, and was educated in his native place. At an early age, he entered the counting house of a merchant, and afterwards owned and commanded a ship which was employed in the London and West India trade, but soon exchanged the seafaring life for the business exclusively of a merchant, in which he was highly successful. At the opening of the revolution, he took a decided part in behalf of the colonies. As early as 1774, when the mother country passed the Boston port bill, and menaced hostilities, Mr Langdon, with John Sullivan and Thomas Pickering, raised a troop, proceeded to the fort at Great Island, disarmed the garrison, and conveyed the arms and ammunition to a place of safety. The royal government would have prosecuted him, but was deterred by the resolution of the inhabitants to shield him at all hazards. In 1775, he was a delegate to the general congress of the colonies. In June, 1776, he resigned his seat in that body, for the place of navy-agent. In 1777, he was speaker of the assembly of New Hampshire, and, when means were wanted to support a regiment, Langdon gave all his hard money, pledged his plate, and applied to the same purpose the proceeds of seventy hogsheads of tobacco. A brigade was raised with the means which he furnished, and with that brigade general Stark achieved his memorable victory over the Hessians. In 1785, Mr Langdon was president of New Hampshire, and, in 1787, delegate in the convention that framed the federal constitution. Under this constitution, he was one of the first senators from New Hampshire. In 1805, he was elected governor of his state, and again in 1810. In 1801, president Jefferson solicited him in vain to accept the post of secretary of the navy at Washington. He died Sept. 18, 1819. Governor Langdon was a conspicuous and efficient public character. In the party politics of the Union, he acted with Mr Jefferson and his associates; but he was honoured and trusted on all sides. The influence of his name was great throughout the Union.

LANGELAND; an island of Denmark, in the south part of the Great Belt, between the islands of Laaland and Funen, about thirty miles in length, and from three to five in breadth; lon. 10° 50' E.; lat. 55° N.; population, about 11,200; square miles, 103. This island is fertile in every part. It is now only a county, but one of the best in the kingdom, and under the same governor as Funen. Rudkiøping is the chief town.

LANGLANDE, ROBERT; a secular priest, and fellow of Oriel college, Oxford, in the fourteenth century, who is supposed to have been the author of the curious poetical compositions, entitled, the Vision of Pierce Plowman, and Pierce Plowman's Crede. He is said to have been a disciple of Wicliffe; and his poems are satires on the vice and luxury of the monastic orders and Romish clergy in general. Editions of these works have been published by doctor T. D. Whitaker. (See Warton's *Hist. of Eng. Poetry*.)

LANGLES, LOUIS MATTHEW, a celebrated Oriental scholar, born at Peronne, in France, 1763, studied Arabic and Persian under M. Silvestre de Sacy, afterwards Mantchou, and published an alphabet of that language in 1787, with a dedication to the academy of inscriptions. This work was followed, in 1788, by a *Dictionnaire Mantchou-François*, after which he printed various pieces translated from the Arabic and Persian. In 1790, he published

Indian Fables and Tales, newly translated, with a preliminary discourse, and notes on the religion, manners, and literature of the Hindoos; and also the second volume of his *Manichou Dictionary*. He was in 1792, nominated keeper of the Oriental MSS. in the royal library; and, in 1793 he belonged to a temporary commission of arts, attached to the committee of public instruction. After the revolution in July, 1794, he became keeper of the literary *depôt*, established in the old convent of the Capuchins, *rue St Honoré*. To his zeal and influence were owing the creation and organization of a particular school for the Oriental living languages, in which he was professor of Persian. He wrote notes for a new edition of the *Travels of Pallas*, translated by Lapeyronie, which he published in 1795 (8 vols., 8vo, with an atlas). He was also the author of valuable additions to the travels of Thunberg, Norden, &c. After the executive directory had suppressed the temporary commission of arts, and dispersed, in various establishments, the objects which had been collected at the Capuchin convent, M. Langlès devoted himself entirely to the duties of his professorship, and to those which devolved on him as conservator of the Oriental MSS. in the national library. On the formation of the institute, he became a member, and belonged to the commission of literature, to which he presented many memoirs and notices of manuscripts. He also assisted in many periodical works. In 1796, in conjunction with MM. Daunou and Baudin des Ardennes, he made an abortive attempt to re-establish the *Journal des Savans*; and the *Magazin encyclopédique* contains a great number of notices and dissertations from the pen of M. Langlès. He died in Jan., 1824. He had formed a noble collection of books, manuscripts, engravings, &c.; and his house was the general resort of travellers, *cognoscenti*, and students.

LANGREL, or LANGRAGE; a particular kind of shot, formed of bolts, nails, and other pieces of iron, tied together, and forming a sort of cylinder, which corresponds with the bore of the cannon from which it is discharged, in order to wound or carry away the masts, or tear the sails and rigging of the adversary. It is seldom used but by privateers or merchantmen.

LANGTON, STEPHEN; a cardinal, and archbishop of Canterbury, in the reign of John, whose disputes with the papal see originated in his rejection of this prelate's appointment. By birth, Langton was an Englishman, but he received his education in the French metropolis. In the university of that city, he had risen gradually, through various subordinate offices, to the chancellorship, when, on going to Rome, the learning and abilities which had hitherto facilitated his advancement raised him so high in the favour of Innocent III., that the pontiff, in 1207, not only elevated him to the purple, but presented him to the vacant primacy of England, respecting the disposal of which the king was then at variance with the monks of Canterbury. John refused to confirm the nomination, seized on the temporalities of the see, and ordered the monks to depart the kingdom. A sentence of excommunication upon himself and his whole realm was the consequence; nor was it removed till the weak monarch, alarmed by the warlike preparations of France, and the general disaffection of his subjects, gave up every point in dispute, and reconciled himself to the church. Langton took possession of his diocese in 1213, and was a strenuous defender of the privileges of the English church. The first division of the chapters of the Bible in verses is attributed to him. De la Rue mentions him among the Anglo-Norman poets of the thirteenth century.

LANGUAGE. This word, originally derived from the Latin *lingua* (tongue), in its most general

sense, means the faculty which God has given to men of communicating their perceptions and ideas to one another, by means of articulate sounds. Metaphorically, its signification is extended to every other mode by which ideas may be made to pass from mind to mind. Thus we say, the "language of the eyes," the "language of signs," the "language of birds and beasts." Even silence, by a bold metaphor, has been assimilated to language by one of the most elegant British poets:—

"Come then, expressive silence, make his frame."  
T. BARNES.

In an analogous sense, philologists call the communication of ideas by writing, *written language*, in contradistinction to language properly so called, which they denominate *spoken language*. It is certain that ideas may be communicated by signs, representative of sounds, which word *representative* must not, however, be taken literally, because there is no point of contact between the sense of seeing and that of hearing; all that can be said is, that, by tacit convention certain visible signs are made to awaken in the mind the idea of certain audible sounds, which sounds, by another tacit agreement, awaken the ideas of physical objects or of moral perceptions. Thus the eye operates on the mind through the medium of the ear; but the process is so rapid, that it is not perceived at the time, and writing may be said even to be a quicker mode of communication than speech, for the eye can run over, and the mind comprehend, the sense of a page of a printed book, in a much shorter space of time than the words which it contains can be articulated. Still the passage of ideas from the eye to the mind is not immediate; the spoken words are interposed between, but the immortal mind of man, that knows neither time nor space, does not perceive them in its rapid flight; and by this we may form a faint idea of what the operations of the soul will be, when freed from the shackles of our perishable frames.

The same principle applies equally to those modes of writing which philologists have denominated *ideographic*, by which it would seem to be implied, that ideas are immediately transmitted through the eye to the mind. Among those is classed the Chinese. But it is well known that every one of the numerous characters of which that writing consists, awakens in the mind the idea of a syllable, which it is meant to represent; and that syllable, in speech, represents a spoken word or part of a word. Thus, in this instance, the ear (the mental ear) is also an intermediate agent between the eye and the mind. (See the article *Chinese Language, Writing, and Literature*; see also a letter from Peter S. Duponceau, Esq., of Philadelphia, to captain Basil Hall, in the *London Philosophical Magazine* for Jan., 1829, where this question is discussed at large.) The same may be said of the Egyptian hieroglyphics. For a long time, it was believed that every one of those signs was the representative of an idea, until the researches of the younger Champollion afforded the most complete proof of their having been chiefly used as alphabetical characters, although their forms indicate a different destination. It would seem that it was originally intended to employ them to represent ideas, not abstractedly, but through words or sentences of the spoken idiom; for wherever a language exists, and all nations have spoken before they wrote, ideas can only occur to the mind in the shapes given to them by the peculiar structure and grammatical forms of that language. That might easily have been done to a certain extent. There was no difficulty in devising signs to awaken in the mind the idea of the sun, the moon, a tree, a house, or other object, perceptible by the sense of sight: physical and even moral qualities might be expressed metaphorically.

as they are in speech ; and even some abstract ideas might be represented as they are with us by our algebraic characters. But this mode of communication was necessarily very limited, and its sense, as well as its method, could only be explained by means of spoken words. This led to an easier process, and the hieroglyphics were turned into alphabetical letters. A number of them continued to be employed in the former mode ; as, in our almanacs, we have characters representing the sun, the moon and her phases, various stars, and the signs of the zodiac. These are hieroglyphics, to all intents and purposes, and every written language (if we may use the term) has more or less of them. The Egyptians have employed them in greater abundance than any other nation. Still those signs awakened ideas in no other forms than those in which they presented themselves to the mind, when clothed in words ; hence we are informed by Champollion, that there were hieroglyphs significative of the articles which, in the Coptic language, are prefixed to substantives. But the article is a part of speech not at all necessary in language, since there are idioms (the Latin, for instance, and, amongst modern languages, the Russian) that are entirely without it ; so that it is evident that even hieroglyphic signs were invented to represent words in the first instance, and ideas through them. Of what is called the *Mexican picture-writing*, we know too little to speak very positively. Unfortunately, the key to those hieroglyphs, which was preserved for a long time after the conquest of Mexico, is now lost. Therefore we cannot say how they were connected with the spoken language. But that such a connection must have existed, it is impossible to doubt ; otherwise, the Mexicans could not, as it is known they did, have communicated, by mere pictures of visible objects, the history of their empire, from generation to generation. The few hieroglyphic signs which our northern Indians cut or paint on the bark of trees, to inform each other of the number of their enemies, of the course they are pursuing, and of the number of scalps they have taken in battle, are so limited in their objects, that they only serve to show the difficulty of establishing a similar mode of communication on a more extensive scale. It would soon produce confusion, unless a method were connected with it, based on the structure and on the grammatical forms of the spoken language. This alone could class the signs in the memory, and furnish a clew to their different significations, as applied to various objects, cases and circumstances. It must be otherwise, however, when men, in consequence of some natural defect, as the deaf and dumb, for instance, have no idea of sounds, and therefore are without a spoken language. Here their ideas are formed from the recollection of the perceptions which they have received through other senses than that of hearing. They, however, invent signs to communicate with each other, either through the organs of sight or by means of touch. It has been observed, that many of these signs seem to have been taught by nature, and are the same in countries far distant from each other. These are to sight and feeling what onomatopœias are to sound, and are much more numerous, because more abounding in analogies. Others of those signs are arbitrary, and that is where analogies either entirely fail, or are more obscure and less perceptible. If of them, however, are very limited, and, if the deaf and dumb were left to themselves, would not enable them to enlarge the circle of their ideas. At the admirable art by which they have been taught to understand our languages, through the application of the sense of sight, and to comprehend the mysteries of their structure and their forms, has opened to them a world of ideas, to which they were

before entirely strangers, and has enabled them to combine them with method, compare them with precision, and draw from them correct inferences. To them words are not sounds, but groups of little figures, which class themselves in their minds, and become a medium by which not only to increase the number of the visible signs by touch or gestures, through which they before communicated together, but to improve and methodise them to a degree which, without the knowledge of language, they never would have attained. This language of signs in our deaf and dumb asylums, has received a degree of perfection, which, in some respects, particularly in the rapidity with which ideas are communicated, places it above speech, although, in others, its inferiority cannot be denied. Those advantages it has derived from the knowledge of the forms and method of spoken language, obtained through its written image. It follows, from what has been said, that speech alone is properly entitled to the name of language, because it alone can class and methodize ideas, and clothe them in forms which help to discriminate their various shades, and which memory easily retains ; that written signs or characters, invented by men who can speak, will naturally awaken ideas, in the forms in which their language has clothed them, so as to convey them to the mind through those well known forms, and consequently through the words or sounds to which they have been given. Those who are deprived, by nature, of the sense of hearing, will make the best use they can of the senses which they possess. We have even known a young woman, born deaf and blind, who, to a certain degree, could understand and make herself understood, by means of touch ; but otherwise, speech is the basis of all other modes of communication between men, and all of them, whatever be their forms, reach the mind only through the recollection of ideas, as clothed in the words of a spoken language.

*Origin and Formation of Language.*—The origin of language is involved in deep obscurity. The greatest philosophers, among whom may be mentioned Leibnitz, J. J. Rousseau, Adam Smith, Dugald Stewart, and many others, have in vain exerted their powers to discover what it is most probable will ever remain to us a profound mystery, at least on this side of the grave. Theories have been accumulated upon theories, systems have been formed, and volumes have been written for and against them ; but it does not appear that we are much better informed, at present, than we were in the beginning. Human knowledge has its bounds, prescribed by the almighty Creator of the universe ; these bounds we may approach to a certain degree, but never pass. However, we may be assured of this undeniable truth, it is not the less certain that the same Being who has set limits to our knowledge has implanted in our souls an ardent desire to extend it as far as possible ; and, as those precise limits have not been revealed to us, and there remains a vast space of debatable ground, we are not prohibited from exerting our best faculties in order to extend our view of that ground as far as our imperfect judgment, aided by our imperfect senses, will permit ; and therefore inquiries of this kind will always be curious and interesting, how often soever they may have been tried in vain. Nor is it less curious to take a retrospective view of the aberrations of the human mind to which these inquiries have given rise. It is unfortunately too true, that, in pursuing them, men have much oftener reasoned *a priori*, than they have sought to come at the truth by means of fair induction from well ascertained facts. It is but lately that philologists have employed themselves in collecting facts, till then unobserved, by means of which some extension of our

knowledge may be gained, though we must not expect that we shall ever be able to penetrate into the secrets of Providence, which, if they were displayed before us it is probable that our weak minds could not ever comprehend. Philologists long bewildered themselves in search of the primitive language. The greatest number of the learned assigned that rank to the Hebrew, it being the language of the holy writings, as they have come down to us from the time of Esdras. But many solid objections have been made to that hypothesis, and it seems now to be generally abandoned. Others saw the primitive language in that of their own country, or in some other idiom of which they were particularly fond. Thus Van Gorp, a Fleming, better known as *Becan* or *Becanus*, was in favour of the Low Dutch, Webb was for the Chinese, Reading for the Abyssinian, Stiernhielm and Ruilbeckius for the Swedish, Salmasius, Boxhorn and Aurelius for the Scythian, Erici for the Greek, Hugo for the Latin, the Maronites for the Syriac. In our day, don Juan Bautista de Erro y Aspiroz, who not long since was one of the ministers of state to the late king of Spain, in a work entitled *El Mundo primitivo, ó Examen Filosófico de la Antigüedad y Cultura de la Nación Bascongada* (printed at Madrid, in 1815), claims that honour for the Basque, which, however, in a former work, entitled, *Alfabeto de la Lengua primitiva de Espanna* (Madrid, 1806), he had only, and with more reason, supposed to be the primitive language of Spain. A partial translation of these works was published at Boston, in 1829, by a learned American, George W. Erving, esquire, late minister of the United States to the court of Spain, and will be read with interest, because, in the midst of his national prejudices, the Spanish author discovers a truly philosophic mind, particularly where he maintains with great cogency of argument, that, because men in the beginning had but few wants, it does not follow that they had few ideas, and that their language was destitute of form or method. (*El Mundo primitivo*, p. 37.) The admirable syntax of the languages of the American Indians has sufficiently proved the correctness of this proposition, which now seems to be generally admitted, though it was at first received with great distrust by the learned world. We shall presently expatiate somewhat more at large upon this subject.

That there was a primitive language, which was spoken by the first parents of mankind, is a fact attested by our Holy Scriptures, and which philosophy is not willing to deny. But what has become of that language, and where is it now to be found? Grotius was of opinion, that though it exists at present nowhere in its original form, yet that traces of it may be found in all the languages now spoken. This was a bold assertion, and which could not proceed from actual observation of facts; for what man ever did, what man ever could, compare all the languages of the earth, so as to ascertain whether or not there are to be found in them traces of a primitive idiom, and, what is still more difficult, to point out what these traces are? One man, however, was found,—a man of extensive learning and erudition, and, at the same time, a pure and an elegant writer, who thought he had discovered the primitive language. This was the celebrated Count de Gébélín, well known as the author of a large work, published at Paris (from 1773 to 1784), containing nine quarto volumes, entitled *Le Monde primitif, analysé et comparé avec le Monde moderne*. This curious work contains etymological dictionaries of the Latin and French languages, in which the author assumes to derive all the words of those idioms from his pretended primitive tongue. He considered speech as an instinct, and every language as a dialect of that

which he called "primitive, inspired by God himself—natural, necessary, universal, and imperishable." So far may a man be carried, by the spirit of system, and enthusiasm for a favourite hypothesis. It needs not be said that Gébélín's imperishable language has perished with him; yet his books may still be read with advantage, because, like Don Quixote, when he is not mounted on his hobby-horse, he shows himself a man of judgment, and of profound thought. Count Lanjuinais has abridged and enriched with notes one of his volumes, entitled *Histoire naturelle de la Parole*—a valuable system of general grammar, held in high esteem by philologists. What gave the greatest appearance of probability to the proposition advanced by Grotius, and many others after him,—that the remains of the primitive tongue are to be found and discerned in all existing languages—a the astonishing affinities which have been discovered between the languages of Europe and those of Western Asia, so that even the German and the Sanscrit have been classed together under the generic name *Germano-Indian*. These affinities really do exist, to a degree that would hardly be believed, if the well-ascertained fact were not too stubborn to be resisted. But as soon as we have crossed the Ganges, and proceed towards China, these analogies vanish, and we find languages entirely different from those of the West, not only in etymology, but in their grammatical forms. In the interior of Africa, in the Australian islands, and on the whole of the American continent, we find idioms of different structure, having characters of their own, and in which it would be vain to seek for traces of the primitive tongue. The late professor Barton, of Philadelphia, and after him professor Vater, of Königsberg, endeavoured to find affinities between the American languages and those of the Tartars and Samoiëds; but their researches produced no decisive results. Here and there they found a few words, which seemed to sound alike, but in such small numbers, and so scattered among the numerous idioms of those nations, that it was not possible to infer even the probability of a former connexion between them; and it is more natural to suppose that chance produced those accidental similarities. See *New Views of the Origin of the Tribes and Nations of America*, by B. S. Barton, Philadelphia, 1797, 1798; and *Untersuchungen über Amerika's Bevölkerung*, von J. S. Vater, Leipzig, 1800.

If we were only to attend to the etymological part of languages, that is to say, to the words of which they are composed, considered merely in relation to the sounds which they produce when uttered, we might still doubt whether the primitive idiom might not yet exist in all of them, corrupted and disguised by time and a variety of accidents which may easily be imagined; but we have at last turned our thoughts to the internal structure of the various modes of speech; and the immense differences which exist, and appear to have existed from time immemorial, between them, lead us irresistibly to infer, which, at first view, would seem to contradict the Mosaic account of the creation, but which we think may still be reconciled with it on scriptural grounds. Were it otherwise, we would not be deterred from our philosophical investigations, convinced as we are that religion and philosophy are sisters, and, though at first they may appear to be opposed, they will, in the end, be reconciled to each other.—When we consider the great variety which exists in the structure or organization—if we may so express ourselves—of the different languages of the earth, and the length of time that has elapsed since that variety has begun to exist, we are at a loss to comprehend how they can all have been derived from one primitive source. We see, in the first place, the Chinese and

its kindred dialects completely monosyllabic ; that is to say, that every syllable of which they are composed, with very few exceptions, has an appropriate meaning and conveys, by itself, to the mind, either a simple or a compound idea. At the opposite end of the grammatical scale, we find the languages of the Indians of the American continent polysyllabic in the extreme, composed of words some of them of an enormous length, while their component syllables have, when separately taken, no meaning whatsoever. The Sanscrit, in Asiatic India, and in the vicinity of China, is also an eminently polysyllabic language, though the roots of its words may be more easily traced than those of the idioms of America. The Sanscrit abounds in grammatical forms, by means of which accessory ideas are conveyed to the mind by regular inflections, evidently the result of a preconceived system. The Chinese has none of those forms : every syllable, every word, conveys a detached idea ; and it wants those connecting vocables which, in other languages, bind the discourse together, and help the hearer to understand the sense of a period. The same differences exist, in a greater or less degree, in all the languages of the earth, ancient as well as modern. No two of them, it is believed, have exactly the same manner of conveying ideas from mind to mind in the form of words ; and, though they may have the same grammatical character in a general point of view, they differ in the details. That is not, however, what we are considering. We mean to speak only of those great and essential differences, in consequence of which languages may be divided into strongly distinguished classes, such as the *monosyllabic* and the *polysyllabic*, the *atactic*, that is to say, those that are devoid of connecting words and of grammatical forms, and the *syntactic*, which possess these in greater or lesser abundance. These differences, it will be said, may have gradually taken place in the course of time, and prove nothing against the common origin from *one* primitive language. Unfortunately for this objection, they may be traced back so far, and have continued so long, that it is impossible to suppose that they may have been thus successively produced. Taking, for instance, only two of the languages of the old world—the Chinese and the Sanscrit,—or, if it be alleged that the latter is no longer spoken, we will take those languages of India which are known to be mediately or immediately derived from it, and which may fairly be considered as its continuation. Now, the Chinese and the languages of India are known to have existed at least 4000 years, the one monosyllabic and atactic ; the other, or the others, polysyllabic and syntactic. It does not appear that, in all that period of time, they have at all approached nearer to each other, and, in their general structure and character, they remain now as they were as far back as we can trace them. The same might be said of the Hebrew and the class of languages called *Semitic*, of the Basque, the Greek, the Teutonic, the Slavonic, the Coptic, the Berber of mount Atlas, and the barbarous languages, as they are called, of Asia, Africa, Polynesia, and America, all of which are more or less ancient, and some of which may be traced as far back as the Chinese and Sanscrit ; and their origin is lost in the night of time. Their organic differences have remained the same, not only for ages, but thousands of ages.

From these facts an inference forces itself irresistibly upon the mind, which is, that in all languages there is a strong tendency to preserve their original structure. From the most remote time that the memory of man can reach, we have never seen a monosyllabic language become polysyllabic, or *vice versa*. Why have not the Chinese, and the Sanscrit

or its cognate languages, in the course of 4000 years, approximated in the least to each other ? Has the Tartar conquest made the least alteration in the structure of the former idiom ? How has the Basque preserved its grammatical forms, different as they are from those of any other language, and surrounded as that handful of ancient Iberians is, and has been for so many ages, by idioms of a character entirely opposite ? How comes it that the polysynthetic forms of the languages of America extend from one end of that vast continent to the other, and that one general grammatical system pervades them all, and appears to have been, from the beginning of time, peculiar to the races of American red men ? The strong tendency of languages to preserve their organic structure can alone account, in a satisfactory manner, for these phenomena. If such a tendency be admitted,—and we do not see how it can be reasonably denied,—it must have existed in the primitive language, as well as in those that are supposed to have been derived from it. But when we see that these have preserved their grammatical characters unchanged for more than 4000 years, we cannot believe that, in the 2000 years preceding, according to the generally received chronology, which makes the world about 6000 years old, language should have suffered so many changes in its organic structure as to form new languages, so essentially and so entirely different from each other in that respect, to say nothing of the difference which exists in the etymology of words ; for between the Chinese and the Cherokee, for instance, it will be difficult to find the least etymological affinity ; and, if the distance of place is assigned as the cause, we will instance the Bengalee—a language spoken in a country not far from China, and which differs from the Chinese full as much as the Mohawk and the Potawatamée. We are therefore forced into the conclusion, that all the languages which exist on the face of the earth are not derived from one, but that they must be divided into classes or genera, to which must be assigned separate and distinct origins. It is not our business to reconcile this theory with the Mosaic records ; we think, however, it may be easily done by supposing (to the contrary of which there is nothing in Scripture) that, at the confusion of tongues, the primitive language, its words and its forms, were entirely effaced from the memory of man, and men were left to their own resources to form new ones, which they did without reference to any pre-existing model. We can in this manner very easily account for all the differences, grammatical as well as etymological, that exist between languages. As to the former, we need only look to the various capacities of the human mind. As the physical eye perceives objects differently, and ascribes to them different shapes and colours, according to the strength of the organ and the point of view from which it contemplates them, so the eye of the mind receives ideas or mental perceptions, according to its various capacities, and to different attending circumstances. What we call ideas, are rapid perceptions, continually fitting before the mental eye. Like objects viewed through the kaleidoscope, they pass before us in ever-changing shapes, and, in endeavouring to fix them on the memory by articulate sounds, the appearance of the moment will decide the form to be given to those representative signs. The man of quick perceptions will try to retain the idea of a whole physical or moral object, or, perhaps, a whole group of objects, in his memory, by means of one single word : another, of slower comprehension, seeing or perceiving a part only, will appropriate a word or a syllable to the expression of that part, and another and another to each of the

other parts that he will successively perceive. In this manner, syntactic and atactic idioms have been respectively formed; the impulse first given has been followed, and thus languages have received various organic or grammatical characters and forms. Let us give an example: At the first formation of a language, one man, by signs or otherwise, asks another to do something; the other, anxious to express his consent at once, and conceiving the whole idea, answers, *Volo*. Another man, whose mind is slower in its operations, divides the idea, and answers in two words, *Ego volo*, or *I will*. Another demand is made, to which the first man does not agree; he answers, *Nolo*; the other says, *Ego non volo*, or *I will not*. Applying this hypothesis to all languages, and their different forms, it will be perceived how, in the beginning, they were framed, and how their various structures have been more or less regular, and more or less elegant in their grammatical analogies, according to the tempers and capacities of the nations that first formed them, and of the men that took the lead in that formation, who may not always have been the most sensible of the whole band; for it is to be presumed that, in those early times, as in our day, the affairs of men were not always directed by the ablest, but oftener, perhaps, by the most forward and the most presuming individual. As to the mechanical or physical part of language, that must have depended on the climate and on the peculiar organizations of individuals.

Although the component sounds of all languages appear very few, they are very numerous, if we consider their almost imperceptible shades and modes of utterance. Hence the difficulties that occur everywhere in acquiring the pronunciation of foreign idioms. Although the organs of speech are the same in all men and races of men, great differences are produced in their utterance of sounds, by the early habit of more or less contracting or expanding certain of the muscles of which those organs are composed. Opening or shutting the mouth, letting out the air more or less freely through the lungs, and other similar causes, produce infinite varieties in vocal sounds and consonant articulations, analogous to those that we perceive in musical instruments, which, like the human voice, are operated upon by touch or pressure, or by the impulsion and expulsion of air. The flute does not produce the same sound with the clarinet or French horn, nor the harpsichord with the violin. Even instruments of the same kind produce different effects, according to the manner in which they are played upon. It is so with the human organs. The first sounds that were uttered, when each language was first invented, gave tone and colour to the rest, and that depended on the first individuals who uttered those sounds, and whom the others imitated or followed. The habits, once fixed, could not easily afterwards be altered. Each language, therefore, had its own articulations, its own accent, and its own tones.

Philosophers have, in general, been of opinion that the invention of languages was a very difficult task, and that it required a very long time—ages, perhaps—to bring an idiom to perfection. We are inclined to be of the contrary opinion. God has given to man, as he has to other animals, all the faculties that are necessary to attain the ends of his creation. These faculties, in animals, we call *instinct*; and by whatever high-sounding names our pride may induce us to call them in ourselves, they are, after all, no more than a power given by the Almighty Being. He made man a social animal, because that was necessary to the purposes of his creation; for the same purposes, it was necessary that men should under-

stand each other, that they should exchange plans, projects and ideas. God, therefore, gave them the means of so doing, and these means consisted of physical organs and mental faculties equal to the task. By means of these faculties, they soon found words by which to convey their perceptions of natural and moral objects to one another, and means to retain them in their memory by some method or order of classification, without which they would have been lost in a confusion of articulate sounds. Hence it has happened that there is no language, however barbarous or uncivilized may be the nation that speaks it, that is not systematically arranged; none, so short, that has not a method of its own, or, in other words, a grammar. They are all reducible to certain grammatical principles, and none has yet been found that cannot be so reduced. The American Philosophical Society has proved to a demonstration, that the languages of the aborigines of America are rich in words and in grammatical forms, and it has been said, that it would rather seem that they were composed by philosophers in their closets, than by savages in the wilderness. (See *Report to the Historical and Literary Committee and Correspondence between Mr Duponceau and Mr Heckerfelder*, in the *Historical Transactions of the American Philosophical Society* vol. 1.) When the writer to whom we allude made use of this expression, we believe that he sought to accommodate himself to ideas generally received, for he must have known that languages are not made by philosophers in their closets, and he must have been aware of the failure of all those who attempted to invent what they called a *philosophical language*. Leibnitz, it is said, once had such an idea; but it is certain that he never tried to carry it into execution; or, if he did, he soon abandoned the senseless project. To such a degree was the presumption of the learned raised, about the middle of the seventeenth century, that it was thought, that an universal language could be made for the use of all mankind. One Bacher, having heard a German prince say, that he would give 300 crowns to him who should discover such a language, wrote a treatise, in which he asserted, and tried to prove, that he had made the discovery. He presented it to the prince, who paid him with compliments, and an invitation to dinner. The work is entitled *Character præ Notitia Linguarum universæ* (Frankfort, 1661), and is now very scarce. In 1680, John Wilkins, dean of Rippon, and afterwards bishop of Chester, published a thick folio volume, entitled an *Essay towards a real Character and Philosophical Language*, which contained an alphabet, a grammar, and a dictionary of his supposed perfect idiom. Afterwards, a M. Faiguet, who is called, in the *French Encyclopædia*, *trésorier de France*, but who, in fact, was only a receiver of public moneys in some provincial town, wrote, for that compilation, a scheme of a philosophical language, with which the editors did not disdain to swell their work, and which remains there as a monument of the folly and presumption of mankind. The productions of this writer and of bishop Wilkins, show the superiority of nature over philosophy. Nature invents, philosophy constructs. These philosophers had no idea of grammatical forms except those of the languages that they knew, and this is to say, those that they had learned at college, and those they had received from their masters. Therefore, neither the monosyllabic system of the Chinese, nor the polysynthetic of the Americans, ever occurred to their minds; all the improvements that they could think of on the forms which they were familiar with, was, to apply to them the principles of little minds, *uniformity*. To show how they went to work, we will give a few short samples of their respective inventions. M. Faiguet thus invents, as

his philosophical language, the substantive verb to be:

Infinitive.	Indicative Present.
Être = <i>as</i>	Je suis = <i>jo as</i>
Avoir été = <i>as</i>	Tues = <i>to as</i>
Devoir être = <i>as</i>	Il est = <i>lo as</i>
Êtant = <i>soit</i>	Nous sommes = <i>no as</i>
	Vous êtes = <i>vo as</i>
	Ils sont = <i>so sa</i>

It is needless to proceed farther: every one will see that the structure of the French language is servilely imitated, with a little of the Latin; and the only improvement, or rather alteration, is a tiresome uniformity in the termination of words. Bishop Wilkins's system is more metaphysical, and of course more complicated. He affects an antithetical arrangement of his words, according to the ideas which they express; thus he says, if *Du* signifies *God*, then *ida* must signify its opposite, or an *idol*; if *dab* be *spirit*, *odab* will be *body*; if *dad* be *heaven*, *odad* will signify *hell*. With respect to dissyllables, if *pida* be *presence*, *pid-as* will be *absence*; if *tadu* be *power*, *tadu-will* be *impotence*, &c. His numerals are as follows:

Pobal, 10;	pobol, 30;	pobel, 30.
Pobar, 100;	pobar, 200;	pobar, 300.
Pobam, 1000;	pobom, 2000;	pobem, 3000.
Poban, 100,000;	pobon, 200,000;	poben, 300,000.

One thousand	six hundred	sixty	six.
Pobam	pobur	pobul	pobu.

His arrangement of words in regular rows of prefixed syllables and terminations, is very different from the order which nature follows in all her works, in the structure of languages as in every thing else. She aims not at a childish uniformity. Hers is not the garden where "grove nods at grove; each alley has a brother," She delights on the contrary, in "pleasing intricacies," and every where introduces an "artful wildness," to "perplex" while it embellishes the scene. But not so presumptuous man. Under the mask of a false philosophy, he sets himself up as a rival to nature, which he neither knows nor understands. True philosophy, in a more humble spirit, observes and studies her noble works, contented to admire, and not presuming to imitate.

All those who have attempted to invent a new language, have taken for their models those that they were most familiar with. Father Lami, however, the author of an esteemed French work upon rhetoric, speaking of the possibility of composing a fictitious idiom, proposes, as a type, the language of the Mongul Tartars, probably to make a show of some little knowledge he had of that tongue. But none of these writers thought of framing a language on abstract principles, founded on the most natural arrangement and concatenation of ideas: even the transitive verbs of the Hebrew and other Oriental languages, including in one word the idea of the objective as well as of the governing pronoun, does not appear to have occurred to their minds. It would have been in vain, however, that they should have sought for a system of grammatical forms more natural than another, since, as we have before observed, all the existing grammatical systems, differing as they do from each other, are equally the work of nature, operating through the minds of men, possessing various physical and moral qualities, and producing different results, though all equally tending to the same end—the intercourse of human minds with each other, through the medium of the organs of speech.

We will not, therefore, stop to inquire whether any of the existing languages are more perfect than the others. Perfection is relative to its object. Whatever is adequate to the end for which it was made, cannot be improved but with respect to some

new objects, to which the times or circumstances require that it should be adapted. And that improvement in language is the work of nature, not of philosophy, literature, or science. Necessity sometimes, and sometimes caprice, introduces new words into a language, and chance directs the choice. The same process takes place in the improvement of languages, or rather in the additions made to them, as in their formation. Words are borrowed from neighbouring idioms, or framed by analogy from those in common use, by the first man who thinks he has occasion for them, and they are adopted, or not, by the multitude, as chance or fashion directs. Words are often introduced without necessity, and without much regard to euphony, or the genius of the idiom. It has lately become fashionable to say *approval* for *approbation*, *withdrawal* instead of *withdrawing*; and many other similar new-coined words are gradually coming into use. These innovations make the language more copious, not more perfect. The synonyms, in process of time, assume shades of difference in their meaning, which are not thought of when the words are first used. But we are constantly asked whether the Greek, that enchants us so much in the works of Homer and Pindar, is not a more perfect language than, for instance, the Iroquois, or the Algonkin. We answer, that it is not. We must not confound *perfection* with *cultivation*. The wild rose that grows in our forests is not less a perfect flower than that which adorns our gardens. The latter is more pleasing to our fastidious senses; but will even the most skilful gardener dare to say that he has perfected the work of his Creator? Languages are instruments which have come perfect from the heads of the makers. But they are played on better or worse by different artists. Homer played well on the Greek: he would have played equally well on the Iroquois. If we are to judge of the perfection of a language by the method and regularity of its grammatical forms, that of the Lenni Lenape, of which we have an excellent grammar, by Zeisberger, published in the third volume of the new series of the American Philosophical Transactions, is far superior to our own English, the most anomalous of all idioms, made up almost entirely of monosyllables, full of sibilants and inarticulate vowel sounds; in short, a language which, *a priori*, would be probably pronounced barbarous and uncouth—but hear that instrument played upon by Milton, Shakspeare, Dryden, Pope! If you think that it is the superior perfection of the language that ravishes your senses, and carries you up to the third heavens, you will be much mistaken. It is only the talent of the immortal artists. It is the art of the gardener, who has cultivated this wild tree, and made it produce delicious fruits. But the perfection of a language does not consist in the regularity or in the anomaly of its forms, in its being compounded of monosyllables or polysyllables, or of such or such consonant or vowel sounds predominating in its utterance. Nature in this, as in all her other works, delights in variety. The imperial lily and the humble violet are alike perfect flowers; the barren pine, the stately oak, and the fragrant orange-tree, are alike perfect plants, various in their organization and in their structure, but all adequate to the end for which they were created. Languages were made for the purpose of communication between men, and all are adequate to that end. We have heard that the Chinese language is so imperfect, that men are obliged, in conversation, in order to explain their meaning, to trace, with their fingers, in the air, the figure of written characters. This is exaggerated. We have seen sensible and intelligent Chinese, who have assured us that they never are at a loss to explain their ideas by spoken words. It happens,

sometimes, even in speaking English, that when we use a word which, being differently written, has different meanings, we spell that word, to show in what sense we understand it. The Chinese probably do the same, by means of their characters, but not to the extent that the love of the marvellous, or incorrect information, has induced some writers to maintain. In the same manner, those who have lived long among the Indians, all concur in assuring us that those nations converse with one another, on all subjects, in their own idioms, with the greatest ease. Our missionaries preach to them, and find no difficulty in making them understand the abstract doctrines of our religion; and what must dispel every doubt upon this point is, that the whole of the Old and New Testaments has been translated, by the venerable Eliot, into the language of the Massachusetts Indians.

Let us cease, therefore, to speak of the comparative perfection of languages with respect to each other. They are various instruments formed by nature, which genius may cultivate and render more pleasing to our senses, but not more adequate to their end, and the organization of which no talent can change, and no genius can imitate. If it be true, as we firmly believe, that languages were various in their original formation, after the traces of the primitive language had, by the divine will, been entirely obliterated from the minds of men, it becomes needless to inquire whether the first language was monosyllabic or polysyllabic, and whether the first words were formed by *onomatopœia*—from an imitation of natural sounds. No doubt there are, in every language, words which have been formed by that kind of process, even in modern times, as, for instance, the word *bomb*. But it does not follow that this has been a general rule. In most of the Indian languages, the word which signifies *thunder* has no resemblance to the noise made by that explosion: for instance, in the Chickasaw, it is *elloha*; Creek, *tenitke*; Huron, *inon*; Cadoes, *deshinin*; Nootka, *twa*; and there are many other languages in which, in that word, no symptoms of *onomatopœia* appear. It is curious, however, to find that, in the language of the Arkansas, the word for *thunder* is *tonno*, and in that of the Yaos, called by De Laet *Javini* (a people of Guiana, now extinct), it is *tonimeru*. Chance will produce such similarities, which, when thus isolated, prove nothing for or against the affinity of languages, or their derivation from each other.

LANGUAGES. See *Philology*.

LANGUEDOC; before the revolution, a large province of France, divided into Upper and Lower; bounded east by the Rhone, which separates it from Dauphiny, the county of Venaissin, and Provence; south by Roussillon and the Mediterranean; west by Gascony, and north by Forez, Quercy and Rouergue. Its extent was about 270 miles in length, and 120 in breadth. The land is, in general, very fertile in grain, fruits, and wine. Toulouse was the capital of Upper, and Montpellier the capital of Lower Languedoc. It is now divided into the eight following departments:

Department.	Chief Towns.
Gard, .. ..	Nîmes.
Hérault, .. ..	Montpellier.
Ardèche, .. ..	Privas.
Lozère, .. ..	Mende.
Tarn, .. ..	Alby.
Upper Garonne, .. ..	Toulouse.
Aude, .. ..	Carcassonne.
Upper Loire, .. ..	Le Puy.

(See *Departments*.)

The celebrated canal of Languedoc commences at Cette, and joins the Garonne near Toulouse, forming a communication between the Mediterranean and the Atlantic. It was constructed in the reign of

Louis XIV., and is about 140 miles in length. See *Canals*.

LANIARD, or LANNIERS; a short piece of rope or line, fastened to several machines in a ship, and serving to secure them in a particular place, or to manage them more conveniently: such are the laniards of the gun-ports, the laniards of the bows, the laniard of the cat-hook, &c. The principal laniards used in a ship are those employed to extend the shrouds and stays of the mast by the communication with the dead-eyes and bitts, so as to form a sort of mechanical power resembling that of a tackle.

LANIGERA; the specific appellation of the chinchilla of South America. The animal which furnishes the beautiful fur known by the name of *chinchilla*, has, until very recently, been almost entirely unknown to naturalists, except through the imperfect account given by the abbé Molina in his natural history of Chile. Living specimens have occasionally been brought to Europe. Unfortunately, however, these specimens all died about the period of their arrival, and no opportunity was allowed of examining them alive. The British magickal society have recently been more fortunate in receiving a living specimen in good health, from which they have published a beautiful representation of the animal, accompanied by an accurate description of its characters. This we copy from the first number of the *Delineation of the Garden and Menagerie of the Zoological Society*, along with Molina's account of the habits of the animal. The length of the body in this specimen is about nine inches, and that of the tail nearly five. Its proportions are close-set, and its limbs comparatively short, the posterior being considerably larger than the anterior. The fur is long, close, somewhat crisped and entangled; grayish or ashy-coloured above, and paler beneath. The form of the head resembles that of the rabbit. The eyes are full, large, and black, and the ears broad, naked, rounded at the tips, and nearly as long as the head. The mustaches are plentiful and very long, the longest being twice the length of the head, some of them black, and others white. Four short toes, with a distinct rudiment of a thumb, terminate the anterior feet: and the posterior are furnished with the same number; three of them long, the middle more produced than the two lateral ones, and the fourth external to the others, very short, and placed to the behind. On all these toes the claws are short, and nearly hidden by tufts of bristly hairs. The tail is about half the length of the body, of equal thickness throughout, and covered with long bushy hairs. It is usually kept turned up towards the back, but can be reverted, as in the squirrels. The *chinchilla*, says Molina, is another species of field-rat, of great estimation for the extreme fineness of its wool, of a rich fur, as delicate as the silken webs of the garden spiders, may be so termed. It is of an active and sufficiently long for spinning. The little comb which produces it is six inches long from the base of the root of the tail, with small, pointed teeth, a few mangle, teeth like the house rat, and a tail of moderate length, clothed with a delicate fur. It lives in burrows under ground, in the open country of the northern provinces of Chile, and is found being in company with others of its species. It feeds upon the roots of various bushy plants which grow abundantly in those parts, and produces twice a year, five or six young ones. It is so docile and mild in temper, that, if taken into the hands, neither bites nor tries to escape. If placed in a bosom, it remains there as quiet as if it were in its own nest. This extraordinary species may produce

be due to its pusillanimity. As it is peculiarly cleanly, there can be no fear of its soiling the clothes of those who handle it, or of its communicating any bad smell to them, for it is entirely free from that ill odour which characterizes the other species of rats. For this reason it might well be kept in houses with no annoyance, and at a trifling expense, which would be abundantly repaid by the profits on its wool. The ancient Peruvians, who were far more industrious than the moderns, made of this wool coverlets for beds and valuable stuffs. To the account of its habits given by Molina, we can only add, that it usually sits on its haunches, and is even able to raise itself up and stand upon its hinder feet. It feeds in a sitting posture, grasping its food, and conveying it to its mouth by means of its fore paws. In its temper it is generally mild and tractable, but it will not always suffer itself to be handled without resistance, and sometimes bites the hand which attempts to fondle it, when not in a humour to be played with. Although a native of the Alpine valleys of Chile, and, consequently, subjected, in its own country, to the effects of a low temperature of the atmosphere, against which its thick coat affords an admirable protection, it was thought necessary to keep it, during the winter, in a moderately warm room, and a piece of flannel was even introduced into its sleeping apartment, for its greater comfort; but this indulgence was most pertinaciously rejected, and, as often as the flannel was replaced, so often was it dragged by the little animal into the outer compartment of the cage, where it amused itself with pulling it about, rolling it up, and slaking it with its feet and teeth. In other respects, it has exhibited but little playfulness, and gives few signs of activity, seldom disturbing its usual quietude by any sudden or extraordinary gambols, but occasionally displaying strong symptoms of alarm when startled by any unusual occurrence. It is, in fact, a remarkably tranquil and peaceable animal, unless when its timidity gets the better of its gentleness.

A second individual of this interesting species has lately been added to the collection by the kindness of lady Knighton, in whose possession it had remained for twelve months previous. This specimen is larger in size and rougher in its fur than the one above described: its colour is also less uniformly gray, deriving a somewhat mottled appearance from the numerous blackish spots which are scattered over the back and sides. It is possible this may be the Peruvian variety, mentioned in the extract from Schmidtmeyer's Travels, as furnishing a less delicate and valuable fur than the Chilian animal. It is equally good tempered and mild in its disposition, and, probably in consequence of having been domiciliated in a private house, instead of having been exhibited in a public collection, is much more tame and playful. In its late abode, it was frequently suffered to run about the room, when it would show off its agility by leaping to the height of the table. Its food consisted principally of dry herbage, such as hay and clover, on which it appears to have thriven greatly. That of the society's original specimen has hitherto been chiefly grain of various kinds, and succulent roots. When the new comer was first introduced, it was placed in the same cage with the other specimen; but the latter appeared by no means disposed to submit to the presence of the intruder. A ferocious kind of scuffling fight immediately ensued between them, and the latter would unquestionably have fallen a victim, had it not been rescued. Since that time, they have inhabited separate cages, placed side by side. Such an isolated fact can, of course, have little weight in opposition to the testimony of

Molina, that the chinchilla is fond of company. It is, nevertheless, a remarkable circumstance, and deserves to be mentioned in illustration of the habits of these animals.

LANJUINAIS, JEAN DENIS, count de, peer of France, member of the academy of inscriptions and belles-lettres for thirty-eight years, a staunch defender of liberal institutions, was born March 12, 1753, at Rennes, of respectable parents. In 1771, he became an advocate in Rennes; in 1775, professor of the canon law; in 1779, member of the estates of Brittany; in 1789, member of the third estate in the constituent assembly, and, at a later period, of the convention. He was the first in the states general, who, in the report on the state of things in his province (Brittany), gave a faithful picture of the oppressions committed by the nobility, and declared the following measures to be the general wish of the nation—the abolition of feudal rights; the abolition of the nobility, and the establishment of a representative constitutional government; offering, at the same time, in the name of his constituency—the *sénéchaussée* of Rennes—to give up its privileges of exemption from several taxes, &c., though enjoyed from ancient times. He opposed, with courage and energy, the arrogant pretensions of the privileged class and the intrigues of Mirabeau, and, at a later period, resisted, with equal firmness, the violence of the Mountain party. The object of his wishes was constitutional liberty; and, when the republic was proclaimed, and Louis XVI. was denounced, he was as zealous in defence of the rights of his prince as he had been, and continued to be, for the rights of the nation. Attacked by the Maratists, and even threatened in the convention by a crowd of insurgents, he displayed great courage and dignity. He afterwards retired to Rennes, where, proscribed by the Jacobins, he lived eight months in concealment. He owed his preservation to his faithful wife, and the heroic fidelity of his servant, Julie Poirier, whom Legouvé has celebrated in his poem *Mérite des Femmes*. After the downfall of the terrorists, Lanjuinais again took his seat in the convention. Soon after, he was chosen president, and opposed the usurpations of Bonaparte. March 22, 1800, he was made senator. Though he had opposed the consulate for life, and the elevation of Bonaparte to the throne, the emperor named him commander of the legion of honour, and created him count. In 1814, Lanjuinais voted for the deposition of Napoleon and the establishment of the provisory government, and aided in preparing the constitution proposed by the senate. Louis XVIII. made him a peer, June 4, 1814. During the hundred days, he repeatedly refused to take the oath of allegiance to Napoleon, and voted against the *acte additionnel*. Napoleon approved of his election, by the city of Paris, to the house of representatives, and his elevation by that body to the place of their president. After the second restoration, Lanjuinais opposed, in the chamber of peers, all the extravagant and arrogant pretensions of the clergy, defended the liberty of the press and individual freedom, the law of election and the charter. He voted against the war with Spain, against the reduction of the *rentes*, and the septennial elections of the chamber. The speeches and writings of count Lanjuinais are profound and comprehensive. Among the latter are his *Mémoires sur la Religion*, which is directed against the extension of the ecclesiastical jurisdiction; his *Constitutions de la Nation Française* (2 vols., 1819); his work on the three Concordates, and some historical essays, chiefly in the *Revue encyclopédique*. In 1806, he was elected a member of the institute, in the class of inscriptions and belles-lettres; and, in 1816, the king confirmed him in this place. Lanjuinais died January 13, 1827.

LANSDOWNE, WILLIAM PETTY, marquis of, was born in 1737. He succeeded to the Irish title of earl of Shelburne, on the death of his father, in 1761, and, in 1763, obtained the office of president of the board of trade, which he resigned to join the opposition led by Mr Pitt (lord Chatham), with whom he returned to office in 1766. When a change of ministry took place, in 1768, he was again displaced, and continued to be a parliamentary antagonist of ministers till 1782, when he was nominated secretary of state for the foreign department. On the death of the premier, the marquis of Rockingham, he was succeeded by lord Shelburne, who was soon obliged to give way to the coalition between lord North and Mr Fox. In 1784, he became an English peer, by the titles of marquis of Lansdowne and earl of Wycombe. He now employed himself in the cultivation of science and literature, and collected a valuable library, the MSS. belonging to which were, after his death, purchased for the British museum. His death took place in 1805. Lord Lansdowne was twice married. By his second wife, lady Louisa Fitzpatrick, he became the father of the present marquis.

LANTERN (*laterna*, Lat.; *lanterne*, Fr.); a common contrivance to carry a lamp or candle in, being a kind of cover usually made of tin, with sashes of some transparent matter, as glass, horn, &c., to transmit the light. Theopompus, a Greek comic poet, and Empedocles of Agrigentum, are the first who have spoken of this kind of illumination. In the *Antiquités d'Herculanum*, vol. viii., will be found represented a collection of ancient lanterns, one of which, of a round form, was discovered in one of the great roads of Herculaneum, in 1760, and another, 1764, at Pompeii, in the vestibule of a house, by the side of a human skeleton. The use to which these instruments were put was various. A modern author has stated, without sufficient proof, however, that the games of the circus, at Rome, and the sacred games in Greece, were celebrated by this kind of light. Plutarch expressly says that they were used in augury. It is more certain still that they were common among the military, and were always carried before any troops who had to march by night. These were borne upon the top of a pike, and were constructed of a fashion to throw light only behind them.

*Dark Lantern*; one with only a single opening, which may also be closed up when the light is to be entirely hidden, or opened when there is occasion for its assistance to discover some object.—See *Magic Lantern*.

*Fest of Lanterns*, in China; a celebrated feast held on the 15th day of the first month, and thus denominated from the immense number of lanterns hung out of the houses, and in the streets, the number of which has been reported even to exceed 200,000,000. Some of these have been valued at 2000 crowns. They are adorned with gilding, painting, jappanning, sculpture, &c. The size of many of these lanterns is represented to be quite huge: some reach nearly thirty feet in diameter. They are constructed so as to resemble halls or chambers; and two or three such machines together would make a handsome house; so that the Chinese eat, lodge, receive visits, have balls, and act plays, in a lantern. They light up in them an infinite number of torches or lamps, which at a distance, have a beautiful effect. In these they exhibit various kinds of shows to divert the people. Besides these enormous machines, there is a multitude of smaller ones, which usually consist of six faces or lights, each about four feet high, and one and a half broad, framed in wood, finely gilt and adorned: over these they stretch a fine transparent silk, curiously painted with flowers, trees, and some-

times with human figures: the painting is very extraordinary, and the colours extremely bright; and when the torches are lighted, the appearance is exceedingly striking and lively.

In architecture, *lantern* signifies a little dome raised over the roof of a building, to give light, and serve as a sort of crowning to the fabric. The same term is likewise used for a square cage of carpentry placed over the ridge of a corridor or gallery, between two rows of shops (as in the royal exchange, London), to illumine them.

The *lantern*, on ship-board, is a well-known machine, of which there are many in a ship, particularly for the purpose of directing the course of other ships in a fleet or convoy; such as the poop and up-lantern.

LANTERN FLY (*fulgora*); a genus of insects, belonging to the *Hemiptera*, and closely allied to the locusts and grasshoppers, from which it is distinguished by the great prolongation of the head. Few circumstances are more remarkable than the phosphoric light emitted by some insects, as by the glow-worm and fire-fly, but more especially by the species under consideration. This is said to possess the lucid quality in so eminent a degree, as to be used by the inhabitants of the countries where they are found, for the purposes of illumination. The largest of these insects is the *F. lateralis*, which is found in great abundance in South America. Madame Mercur gave an entertaining account of the alarm into which she was thrown by the light produced from them, when she was apprised of their shining nature. It appears the Indians brought her a number of the lantern flies shut up in a box. During the night, they made such a noise, that they awoke her, and induced her to open the box, when, to her astonishment and alarm, a strong light proceeded from it, and as many of the insects as left it, so many flames appeared. There are many other species of these flies, one of which—the Chinese—almost equals the South American in splendour. In both of those, the light proceeds from the elongated and hollow part of the head, so other portion of the animal being luminous. A full account of all the species will be found in Fabricius, *Sp. Rhynch.*, and Olivier, *Encycl. Method.*, article *Fulgora*.

LANZI, LUIGI, the celebrated archaeologist, was born at Treia, in the Mark of Ancona, in June, 1731, and became a pupil of the Jesuits, and a member of the order. He made himself master of the whole field of classical studies, and the ruins of Rome awakened his curiosity to the examination of the remains of ancient art, in treating of which he evinced profound learning and critical acumen. From Rome, Lanzi went to Florence, and made himself acquainted with all the masterpieces of art collected there. In 1782, he published a *Guida della Galleria di Firenze*, on which he laboured during the rest of his life. This work not only satisfied the inquirer by its extensive learning, but amused the mere searcher after pleasure, by its pleasing descriptions. He was chosen president of the *Accademia*, in 1807, on account of the purity of his language. A patriotic feeling had engaged Lanzi in the study of Etruscan antiquity, which was then little cultivated. Learned Tuscans, in the middle of the eighteenth century, had attempted to elevate Etruscan civilization, by maintaining that the Etruscan religion and mythology were entirely unaffected by Grecian influence. Lanzi's researches led him to form a different opinion. The remains of the Etruscan language and art denoted, in his opinion, a Grecian origin, and disclaiming all national vanity, he openly maintained the prevailing influence of Greece on Etruscan civilization. German scholars have adopted his opinion.

A critical method and profound erudition render his *Saggio di Lingua Etrusca e di altre antiche d'Italia, per servire alla Storia de' Popoli, delle Lingue e delle Belle Arti* (Rome, 1789, 3 vols.), a classical work. Lanzi next undertook a history of the art of painting in Italy, at the suggestion of the grand-duke of Tuscany (who died in 1824); and this work is of equal merit with that just mentioned. The charms of his style render this erudite production highly attractive. Of this *Storia pittorica dell'Italia dal Risorgimento delle Belle Arti fin presso al Fine del XVIII. Secolo*, the third edition (Bassano, 1809, 6 vols.) deserves the preference, as containing his own last additions. The first edition appeared in 1795, the fourth in 1822 (Florence; English, by Thomas Roscoe, London, 1828). His *Inquiries respecting the Etruscan Vases*, so called (Florence, 1806), is a work of great learning, the most valuable treasures of which have been still more generally diffused by Millin. He also published *Latin Inscriptions, which are much esteemed*, a translation of Hesiod's *Works and Days*, and some theological productions, the fruit of his last years. Since his death, which took place March 30, 1811, some of them have been collected by the cavalier Onofrio Boni, in the *Opere Postume* (Florence, 1817, 2 vols., 4to). Inghirami published, in 1824, a new edition, with corrections and additions, of Lanzi's *Notizie della Scultura degli Antichi*, with engravings. As a man, Lanzi was amiable, and readily assisted others in their researches and learned labours. He was buried in the church of Santa Croce, at Florence, where the remains of so many great men repose. Onofrio Boni of Crotone has written an *Elogio dell' Ab. D. Luigi Lanzi*, and the abbate J. B. Zannoni, sub-librarian at Florence, a biography of this distinguished man.

LAOCOON, a priest of Neptune (according to some, of Apollo), at Troy, after the pretended retreat of the Greeks, was sacrificing a bull to Neptune, on the shore, when two enormous serpents appeared swimming from the island of Tenedos, and advanced towards the altar. The people fled; but Laocoon and his sons fell victims to the monsters. The sons were first attacked, and then the father, who attempted to defend them. Wreathing themselves round him, the serpents raised their heads high above him, while, in his agony, he endeavoured to extricate himself from their folds. They then hastened to the temple of Pallas, where, placing themselves at the foot of the goddess, they hid themselves under her shield. The people saw, in this omen, Laocoon's punishment for his impiety, in having pierced with his spear the wooden horse, which was consecrated to Minerva. Thus Virgil (*Æn.* ii. 199) relates the story. Other authors, for instance, Hyginus, give different accounts, though agreeing in the main points. The story has frequently furnished a subject to the poets. Sophocles introduced it into a tragedy. But it is chiefly interesting to us, as having given occasion to one of the finest works of sculpture—the group of Laocoon, now in the Vatican. This was discovered in 1506, by some persons digging in a vineyard, on the site of the baths of Titus. Pope Julius II. bought it for an annual pension, and placed it in the Belvedere, in the Vatican, where it has again been placed since its restoration from Paris. The reservation is perfect, except that the right arm of Laocoon was wanting: this was restored by a skillful pupil of Michael Angelo. This group is so perfect a work, so grand, so instructive for the student of the fine arts, that many authors of all nations, particularly Germans, have written on it; of whom we may mention Goethe, Heyne, Lessing, Hirt, Herder. It is a most difficult subject. It represents three persons in group, but in different attitudes of struggling or fear,

according to their ages, and the mental anguish of the father. All connoisseurs declare the group perfect, the product of the most thorough knowledge of anatomy, of character, and of ideal perfection. According to Pliny, it was the common opinion that this group was made of one stone, by the sculptors Agesander, Polydorus, and Athenodorus, all three natives of Rhodes, and the two latter probably sons of the former. Doubts exist respecting the era of this work. Maffei places it in the eighty-eighth Olympiad, or the first years of the Peloponnesian war; Winckelmann, in the time of Lysippus and Alexander; Lessing makes it probable that those three artists lived under the first emperors. It may be fairly doubted whether the statue, mentioned by Pliny, is the same which we now have; at least, acute observers have found that the group does not consist of one block, though the junctions are very carefully concealed. To this it may be answered, that they were not, perhaps, perceptible in the time of Pliny. Several copies exist of this matchless production; one in bronze, from a model by Giacompo Tatti or Sansovino, which was carried to France. Bacio Bandinelli made a copy, which is in the Medici gallery, at Florence. The group is placed on a pedestal, about the height of a man, which seems to be too low, Laocoon being above the natural size. Lessing wrote a work, called *Laocoon*, or the Boundaries of Painting and Poetry, in which he draws illustrations from this subject, because it has been handled by a poet and by plastic artists.

LAODICE; 1. a daughter of Priam and Hecuba, who became enamoured of Acamas, son of Theseus, when he came, with Diomedes, from the Greeks to Troy, on an embassy, to demand the restoration of Helen. She had a son by Acamas, whom she called Munitus. She afterwards married Helicaon, son of Antenor, and Telephus, king of Mysia. Some called her Astyoche. According to the Greek scholiast of Lycophron, Laodice threw herself down from the top of a tower, and was killed, when Troy was sacked by the Greeks.

2. One of the Oceanides.

3. A daughter of Cinyras, by whom Elatus had some children.

4. A daughter of Agamemnon, called also *Electra*.

5. A sister of Mithridates, who married Ariarathes, king of Cappadocia, and afterwards her own brother, Mithridates. During the absence of Mithridates, she prostituted herself to her servants, believing that her husband was dead; but when she saw her expectations frustrated, she attempted to poison Mithridates, for which she was put to death.

6. A queen of Cappadocia, put to death by her subjects for poisoning five of her children.

7. A sister and wife of Antiochus II. She put to death Berenice, whom her husband had married. She was murdered by order of Ptolemy Euergetes.

8. A daughter of Demetrius, shamefully put to death by Ammonius, the tyrannical minister of the vicious Alexander Bala, king of Syria.

9. A daughter of Seleucus.

10. The mother of Seleucus.

LAODICEA; a city of Asia, on the borders of Caria, Phrygia, and Lydia, celebrated for its commerce and the fine wool of its sheep. It was originally called *Diopolis*, and afterwards *Rhoas*. It received the name of *Laodicea*, in honour of Laodice, the wife of Antiochus. There were several other places of the same name.

LAOMEDON; in fabulous history, the son of Ilus, king of Troy. He married Strymo, called by some *Placia* or *Leucippe*, by whom he had Podarces, afterwards known by the name of *Priam*, and Hesione. He built the walls of Troy, and was assisted by

Apollo and Neptune, whom Jupiter had banished from heaven, and condemned to be subservient to the will of Laomedon for one year. When the walls were finished, Laomedon refused to reward the labours of the gods; and, soon after, his territories were laid waste by the sea, or Neptune, and his subjects were visited by a pestilence sent by Apollo. Sacrifices were offered to the offended divinities, but the calamities of the Trojans increased, and nothing could appease the gods, according to the words of the oracle, but annually to expose to a sea-monster a Trojan virgin. Whenever the monster appeared, the marriageable maidens were assembled, and one was doomed to death, by lot, for the good of her country. When this calamity had continued for five or six years, the lot fell upon Hesione, Laomedon's daughter. The king was unwilling to part with a daughter whom he loved with uncommon tenderness, but his refusal would irritate more strongly the wrath of the gods. In the midst of this fear and hesitation, Hercules came, and offered to deliver the Trojans from this public calamity, if Laomedon would promise to reward him with a number of fine horses. The king consented; but, when the monster was destroyed, he refused to fulfil his engagements, upon which Hercules besieged Troy, and took it by force of arms. Laomedon was put to death after a reign of twenty-nine years; his daughter Hesione was given in marriage to Telamon, one of the conqueror's attendants, and Podarces was ransomed by the Trojans, and placed upon his father's throne. According to Hyginus, the wrath of Neptune and Apollo was kindled against Laomedon because he refused to offer on their altars, as a sacrifice, all the first-born of his cattle, according to a vow he had made.

LAON, BATTLE OF, March 9, 1814. See *Châtillon*.

LA PARLE; the chief village of a French colony in the south of Africa. About 150 years ago, a number of French Protestants fled to that distant corner of the world, to worship freely, according to the dictates of their consciences. In 1739, the Dutch prohibited preaching in French; Dutch is therefore, at present, the chief language. The colony consists of about 4000 whites of French descent, and 6000 Hottentot slaves. The whites still possess the greatest attachment to France, though for so long a time separated from the civilised world. The colony has lately attracted attention through French missionaries, and may become important in the propagation of Christianity in that region.

LAPÉROUSE, JOHN FRANCIS GALAUP DE; a French navigator, distinguished for his talents, and still more remarkable for the mystery attending his fate. He was born at Albi, in Languedoc, in 1741, and entered, at an early age, into the naval service of his country. During the American war, he had the command of an expedition sent to Hudson's bay, when he destroyed the trading establishments of the British. After the restoration of peace, the French government having determined on the prosecution of a voyage of discovery, M. de Lapérouse was fixed on to conduct the undertaking. Two vessels—the *Boussole* and the *Astrolabe*—were placed under his command; and, leaving France in 1785, he proceeded to the South sea, and, having visited the coast of California, and other places farther north, he crossed the Pacific, to continue his researches on the eastern coasts and islands of Asia. In April, 1787, the ships sailed from Manilla towards the north; and, after passing the islands of Formosa, Quelpaert, the coasts of Corea and Japan, they sailed between Chinese Tartary and Saghalien, without being able to determine whether it was

an island or a peninsula; returning south, discovered the straits which bear the name of *Lapérouse*, and, sailing north on the eastern coast of Saghalien, at length, September 6, arrived at the harbour of St Peter and St Paul, on the coast of Kamtschatka. There they staid to refit the ships, and experienced the utmost hospitality from the Russian local authorities. From St Peter and St Paul, Lapérouse sent copies of his journals, &c., to France, by M. de Lesseps, who proceeded over land across Siberia to Petersburg. From these papers was drawn up the relation of his voyage, published at Paris (1797, four volumes 4to.), an English translation of which appeared in 1798 (three volumes 8vo.). September 30, the vessels sailed in search of further discoveries. They crossed the equinoctial line without meeting with any land, till December 1, when they saw the Navigator's islands, and, a few days after, they landed at Maouma, one of this group. Here M. de Langle, the captain of the *Astrolabe*, M. Lamanon, the naturalist attached to the expedition, and ten other persons, were killed; a what appears to have been an unprovoked attack of the natives. After this misfortune, Lapérouse visited Otolava, an island near Maouma, and then steered for the English colony in New South Wales. January 23, 1788, they made the coast of New Holland, and, on the 26th, anchored in Botany Bay. They left Botany Bay in March, and, in a letter which the commodore wrote February 7, he stated his intention to continue his researches till December, when he expected, after visiting the Friendly islands, to arrive at the Isle of France. This was the latest intelligence received of the fate of the expedition; and M. d'Entrecasteaux, who was despatched by the French government, in 1791, in search of Lapérouse, was unable to trace the course he had taken, or gain any clue to the catastrophe which had befallen him and his companions. In 1825, the attention of the public was excited towards this mysterious affair, by a story published by the French minister of the navy, purporting that an American captain had declared that he had seen, in the hands of one of the crew of an island in the tract between Louisiana and New Caledonia, a cross of the order of St Louis, and some medals, which appeared to have been procured from the shipwreck of Lapérouse. In consequence of this information, the commander of a vessel which sailed from Toulon, in April, 1826, on a voyage of discovery, received orders to make researches in the quarter specified, in order to restore to their country any of the shipwrecked crew who might yet remain in existence. Other intelligence, relative to the wreck of two large vessels, on two different islands of the New Hebrides, was obtained by captain Dillon, the commander of an English vessel at Turoia, in his passage from Valparaiso to Pondicherry, in May, 1826, in consequence of which he was sent back to ascertain the truth of the matter. The first discovered by him on this mission, were that two ships struck on a reef at Mallicolo, 11° 4' latitude, 160° 20' E. longitude; one of them immediately went down, and all on board perished; some of the crew of the other escaped, part of whom were murdered by the savages; the remainder in a small vessel, and set sail from Mallicolo; but what became of them is not known. It is not, indeed, certain that these were the vessels of Lapérouse.

LAPIDARY, in the preparation of gems in sculpture; an artifice who cuts precious stones. This art is of great antiquity. There are various machines employed in the cutting of precious stones, according to their quality. The *Jauchel*, which

extremely hard, is cut in a wheel of soft steel turned by a mill, with diamond dust, tempered with olive-oil, which also serves to polish it.

**LAPIDARY STYLE** (from the Latin *lapis*, stone); that which is proper for inscriptions on monuments. Hence the phrase is sometimes used for a laconic, expressive style.

**LAPIDOLITE.** See *Mica*.

**LAPIS LAZULI.** This superb mineral, which has been seen regularly crystallized only in a few instances, occurs massive, of a rich azure-blue colour; fracture uneven; scratches glass; opaque; easily broken; specific gravity, 2.85. In a strong heat, it intumesces, and melts into a yellowish-black mass. It consists, by one analysis, of 46 silex, 28 lime, 14.5 alumine, 3 oxide of iron, 6.5 sulphate of lime, and 2 water; but a later and more interesting research has given 34 silex, 33 alumine, 3 sulphur, and 22 soda. The finest specimens are brought from China, Persia, and Great Bucharia. It is much esteemed for ornamental purposes, especially for inlaid work. The most splendid exhibition of this rare substance is made in the celebrated marble palace built by Catharine, at St Petersburg, for her favourite Orlov, in which, according to Patrin, there are entire apartments inlaid with lapis lazuli. The ancients were in the habit of engraving upon it, of whose works several specimens are to be seen in the royal library at Paris. But its chief value consists in its affording the very precious pigment called *ultramarine*. (q. v.)

**LAPITHÆ**; a people of Thessaly. The chief of the Lapithæ assembled to celebrate the nuptials of Peirithoos, one of their number. The Centaurs were also invited to partake the festivity, which was interrupted by the violence of the Centaurs. The Lapithæ resented the injury. Many of the Centaurs were slain, and they, at last, were obliged to retire. (See *Pirithoos* and *Centaurs*.) Hesiod (*Scut*) and Ovid (*Met.* xii.) have described the battle of the Centaurs and Lapithæ.

**LAPLACE, PIERRE SIMON**, marquis de, a celebrated mathematician and astronomer, was born at Beaumont-en-Auge, in the department of Calvados, in March, 1749. The circumstances of his parents were extremely humble, and he was indebted for the means of acquiring his early instruction to the generosity of some rich individuals to whom his uncommon talents and astonishing aptitude for mathematical studies had accidentally become known. The expectations which had been formed of him were quickly realized by the great rapidity of his progress, which was such that at a very early age he was appointed a professor of the mathematics in the college of his native town. This field, however, soon appeared too confined for his aspiring views, and he abandoned it in a short time in order to prosecute his studies with greater advantages, and seek his fortune in Paris. In the capital, the brilliant talents of the young geometer soon procured him protectors; among others d'Alembert, who admitted him to his friendship, and in some measure directed his first steps in the career of the sciences. Laplace profited so well by the counsels and lessons of this illustrious master, that in a short time he signalized himself by the capital discovery of the invariability of the mean distances of the planets from the sun, and by the establishment of some theories of great importance in analysis. His first essays were made under the auspices of the president Saron, to whom he dedicated his works, and who defrayed the expense of their publication. Through this high patronage, which he had sufficient dexterity to turn to the greatest account, he was appointed to succeed Bezout in the situation of examiner of the royal corps of artillery; an office which

left him sufficient leisure to prosecute the studies which he had commenced with such distinguished success. At the early age of twenty-four he was admitted into the Academy of Sciences, and from this time devoted himself with ardour to the composition of a series of memoirs on the most important questions of physical astronomy, and to the development in all their details, of the consequences that result from the general laws which regulate the system of the universe. Besides these and other researches connected with the improvement and extension of mathematical science, his attention was turned successfully to the investigation of the principles, and to the experimental researches of chemistry; and, associated with his illustrious and unfortunate friend, Lavoisier, he was the first to repeat in France the experiments of Cavendish to effect the decomposition of water. During the Revolution, when distinguished excellence of any kind was considered by those who had possessed themselves of the executive power of the state as a sufficient cause for proscription, Laplace was several times in danger of meeting a premature fate. It must, however, be admitted that he was not one of those retiring unobtrusive sons of genius who gladly relinquish the objects of political ambition for the calm pursuits of philosophy; on the contrary, he entered into all the frenzies of that distracted period with the same enthusiasm which he displayed in his other occupations; and the extravagant and even ridiculous excess to which he carried his professions in favour of liberty, equality, and republicanism, especially when contrasted with the suppleness and subserviency of his subsequent political conduct, greatly diminished the respect which would have been willingly yielded to his profound genius and distinguished services in the cause of science. At the establishment of the Polytechnic School he was appointed one of the professors in that admirably conceived institution. In 1796 he did homage to the Council of Five Hundred by presenting to them his *Exposition du Système de Monde*; a work which was received by the scientific world in general with unbounded admiration. In 1799, he was nominated by the Consuls to the ministry of the interior. In this situation he soon found, probably, that the effects of human passions are not so easily submitted to the calculus as those of the forces of nature; at all events his success as a minister of state was by no means commensurate with his high reputation as a mathematician. Bonaparte, who himself aspired to the renown of science, and who always manifested the most friendly dispositions towards Laplace, said of him, in reference to the inaptitude which he displayed in the management of practical matters, that he never seized any question in its true point of view, that he sought for subtleties in every thing, that his ideas were problematical, and that, in short, he carried into the administration the spirit of the infinitesimal calculus. The same year he was called to a place in the senate: of which body he was subsequently vice-chancellor and president. In 1806, he was raised to the dignity of Count of the Empire. But although he was indebted for all these offices and honours to the personal favour of Bonaparte, yet, on the emperor's reverse of fortune in 1814, he was one of the first to push matters to extremity against his ancient benefactor, and to vote for the overthrow of the imperial power, and the establishment of a provisional government. On the re-establishment of the Bourbons, the facility with which he had deserted his former master, and his zeal in the service of the restored dynasty, were rewarded with the title of marquis, and a seat in the chamber of peers. How different the fate of his amiable and more upright and consistent colleague Monge, who,

on the same occasion, was stript of his employments, and had his name erased from the list of the Institute, because he had the magnanimity to respect, in his fallen fortunes, the man whom he had professed to reverence and admire in the plenitude of his power. In 1816, Laplace was named a member of the French Academy, an honour to which he was eminently entitled by the admirable clearness, and purity, and elegance of his style. He died in March, 1827, full of years and glory. His principal works are his *Traité de Mécanique céleste* (1799—1805, four vols., 4to); his *Théorie du Mouvement des Planètes*; *Essai sur les Probabilités*; and *Théorie analytique des Probabilités*.

**LAPLAND**; the most northern country in Europe, bounded north by the Arctic ocean, east by the White sea, south by Sweden, and west by Norway and the Atlantic. Its extreme breadth is estimated to be 500 miles, and its length, from cape Orlof, on the White sea, to the entrance of Saltersford, on the Atlantic, about 700. Lapland is divided into three parts, called *Russian*, *Swedish*, and *Danish*, or *Norwegian*. The part of Lapland lying along the northern shore of the gulf of Bothnia, consists of an extensive plain, abounding in immense forests of spruce and Scots fir; but at the distance of eighty miles from that inland sea, the ground becomes gradually elevated, and is at last full of lofty mountains, which rise, between the latitude of  $67^{\circ}$  and  $68^{\circ} 30'$ , to a height of from 5500 to 6200 feet, which, in this hyperborean region, is 2700 feet above the line of perpetual congelation. The principal rivers are the Torneo, the Kemi, the Lulea, and Pitea. The Yana, the principal river in the north-east, and the Alten, the principal in the north-west, both run into the Northern ocean. In lakes, Lapland, particularly its mountainous part, abounds. In the maritime districts, there prevails an approach to uniformity of temperature; the winters are not severe, but the summers are raw and foggy; while, in the interior, the winter is intensely cold, but the heat of summer is steady and fructifying. The mean annual temperature at the North Cape (lat.  $71^{\circ} 11' 30''$ ) is six degrees higher than at Enontekis, in the interior (in lat.  $68^{\circ} 30'$ ); yet, at the latter, the thermometer rises, in July, to  $64^{\circ}$ , while, at the Cape, it seldom reaches  $50^{\circ}$ . Lapland abounds in iron; and copper, lead, zinc and arsenic are not uncommon. Barley, or big, is the most common grain. In the low ground, rye is likewise cultivated, and occasionally oats. The berry-bearing plants also are numerous. The most common animals are hares; the others are bears, martens, gluttons, beavers, otters, ermines, squirrels, lemmings (or mountain rats), foxes, and wolves. The domestic quadrupeds are oxen, cows, dogs, sheep and goats. The reindeer is the most valuable animal in Lapland. It serves as the principal beast of burden; its milk is highly valued, and its flesh supplies the chief nourishment of the inhabitants. The mountain Laplanders have no fixed habitation, but wander about in quest of food for their flocks of reindeer, and lodge in tents or huts, which are usually about nine feet in height, and twelve in length. Their diet is chiefly of animal food. During winter, they carry on some traffic with the Swedes. This takes place at Torneo, and other towns on the gulf of Bothnia, and consists in exchanging skins, furs, dried fish, venison, and gloves, for flannel, cloth, hemp, copper, iron, and various utensils, but particularly for spirituous liquors, meal, salt and tobacco. The Laplanders, or, as they call themselves *Same*, (*Laplander*, or *Lappe*, being merely a nickname), are a nation of Finnish extraction. The population is estimated thus: 1900 in Swedish Lapland, nearly 5000 in Norwegian, and 8800 in Russian. Besides these, there are in the country several colonies of

Swedes, Norwegians and Fions. The whole population of the country, which is as large as France, cannot exceed 65,000. The height of the Laplanders is between four and five feet; often less. They are of a dark complexion, with black hair; strong, handy and active. They are naturally gentle and mild; have no characteristic vices nor virtues. Generally speaking, they have little excitability, but love their country, and are happy in their way. They can make twine of the sinews of the reindeer, weave coverings for their tents, knit gloves, make wooden utensils, canoes, sledges, and the necessary articles of dress. The dress of both sexes is nearly the same, that of the women is almost solely distinguished by their ornaments. Both sexes wear caps, coats, trousers and boots, either of leather or fur and canvas cloth. In summer, they live in tents; in winter, in huts built of poles covered with birch twigs and earth, having at the top a hole for the smoke. They live on fish and the flesh of reindeer. According to their food, the Laplanders are divided into *Reindeer Laplanders* or *Mountain Laplanders*, and *Fishing Laplanders*. The former wander from pasture to pasture with their reindeer. A wealthy *Laplander* possesses a thousand or more of these animals, which are used to draw the sledges, and to carry loads. The *Fishing Laplanders*, however, who possess few or no reindeer, live almost entirely on fish. They kill saibles and birds, and catch the eider-duck, as do also the *Reindeer Laplanders*, if, by disease or other misfortunes, they lose their reindeer. The *Laplanders* formerly worshipped fetiches. At present, they are all baptised, but they have mixed their old superstitions with Christianity, which has been forced upon them; and it is not uncommon for a *Laplander* to be baptised whenever he comes to a populous place where there are missionaries.

**LAPO**, ARNOLPH, a celebrated sculptor and architect, born at Florence, 1232, first introduced a better taste into architecture by his great works, and very happily united solidity and grace. He began the building of the cathedral of Florence (to which Brunelleschi afterwards added the admirable dome), the strong walls of Florence, the convent at Assisi, and several churches and other edifices at Florence. He died in 1300.

**LAPSE**, in ecclesiastical law; a slip or omission of a patron to present a clerk to a benefice within six months of its being void; in which case, the benefice is said to be in *lapse*, or *lapsed*, and the right of presentation devolves to the ordinary.

**LAPSED LEGACY** is where the legatee dies before the testator, or where a legacy is given upon a future contingency, and the legatee dies before the contingency happens.

**LAPSIDED**; the state of a ship which is built in such a manner as to have one side heavier than the other, and, by consequence, to retain a constant heel or inclination towards the heavier; unless when she is brought upright by placing a greater quantity of the cargo or ballast on the other side.

**LAPWING** (*tringa vanellus*, Lin.). This bird is about the size of a pigeon, and belongs to the snipe and plover tribe. It is found in Europe in large flocks, except during the pairing season, when it separates for the purposes of incubation. The female lays five eggs, of a dirty olive, spotted with black: she makes no nest, but deposits them upon a little dry grass, rudely scraped together: the young birds run about very soon after they are hatched. During this period, the old ones are very assiduous in their attention to their charge: on the approach of any person to the place of their deposit, they flutter round his head with great inquietude, and if he persists in advancing, they will endeavour to dash

him away, by running off as if lame, and inviting pursuit. These birds have a singular mode of collecting their food, which consists of worms. When they observe the small elevation in the ground which the worm makes before it returns below ground, in the morning, by emptying itself, they gently open it at top with their bill, and tap on the ground, at the side of it. This attracts the worm to the surface, when it becomes the prey of the ingenious hunter. These birds are very lively and active, being almost continually in motion, sporting and frolicking in the air, in all directions, and assuming a variety of attitudes. They run along the ground very nimbly, and spring and bound from spot to spot with great agility. In the month of October, they are very fat, and are then said to be excellent eating. Their eggs are considered a great delicacy, and bring high prices in the London markets.

**LAQUERING**; the laying on metals coloured or transparent varnishes, to produce the appearance of a different colour in the metal, or to preserve it from rust. Thus laquered brass appears gilt, and tin is made yellow. Seed-lac is the chief composition for laquers, but turpentine makes a cheaper laquer.

**LARBOARD**; a name given by seamen to the left side of a ship, when the spectator's face is turned in the direction of the head.

**Larboard-Tack** is when a ship is close-hauled, with the wind blowing on her larboard side.

**LARCENY** is the fraudulent taking by a person of the goods of another, without his consent, with the intent, on the part of the taker, to appropriate them to his own use. As to the taking, the mere removing of the goods is sufficient to constitute the crime; as, where the thief took down goods and put them into a parcel, for the purpose of carrying them away, but was detected and arrested before carrying them away, this was held to be a sufficient taking to constitute larceny. But, where a person only changed the position of a package of cloth, by raising it on end, for the purpose of taking out the cloth from the pile, and was detected in his purpose before he had opened the bale, this was held not to be a sufficient taking to amount to this offence. The doctrine, in this respect, is, that, to make the crime of larceny, a person committing it must get the article into his possession. The intent is a material circumstance; and, if one person takes the goods of another openly, before his eyes, though with the design of appropriating them to his own use, it is not larceny, but only trespass; so, if goods be taken by negligence or mistake, it is not larceny; as if sheep stray into one's field, and he shears them by mistake, as his own. The necessity of an intention to steal, in order to constitute larceny, is illustrated by the case of a servant assisting some thieves to steal his master's goods, with the consent of his master, merely that the thieves, who had previously formed the design of committing the theft, might be detected: it was held that larceny on the part of the servant, but it was held to be so on the part of the others, though it was acted, in their behalf, that the taking was not without the consent of the master, it being essential to larceny, that it should be committed against the owner's consent; but the court held it to come under the description of crime, for the thieves had previously formed the design of stealing the goods, and the master did not consent to their appropriating them to their own use, but only to their proceeding so far that they might be detected and convicted of the crime.

A person has property in goods, and a right to possession of them, he cannot, in general, commit the crime of larceny in taking them, but, if he only has the custody of them, and no property in them,

he may steal them. Thus, if a bailee or lessee of chattels appropriates them to his own use, it is not, in general, larceny. Yet it has been held that, when a common carrier, having charge of a package or box of goods, opens it and takes out a part of the goods, with the intent to steal them, this is theft. But the common law makes a very subtle distinction in this respect; for, though breaking the package, and taking a part, with the design of appropriating the articles, is theft, yet selling the whole package entire has been held not to be so, but only the violation of a trust. The cases where a chattel is taken by a person to whom it has been intrusted, and who converts it to his own use, present very nice discriminations of larceny from mere breaches of trust, in regard to which the distinction is made by various circumstances. If the person gets possession of the goods under a false pretence, with the design of stealing them, yet, if they come into his possession on a contract or trust, it has been held, in many cases, not to be a larceny; as, where a horse was bargained for at a fair, and the purchaser rode him off, saying he would return directly and pay the purchase money, but did not come back at all, having intended to swindle the vender, it was held not to be theft. If, however, the purpose for which the article was intrusted to another is accomplished, and he afterwards converts it to his own use, with the intention of stealing it, this is larceny; as, where a horse was let to go to a certain place and back, and the hirer, having gone and returned, then sold the horse, it was held to be theft, for, the particular purpose for which the horse had been intrusted to him, had been served. And the courts generally lean towards construing the offence to be a larceny, and not merely a trespass, where the party gains possession by some false pretence, with the original intent to steal; and with good reason, since it is adding a breach of trust to the crime of larceny. If the owner does not part with the possession of the goods, though the person, intending to steal them, contrives to bring them within his reach by some false pretence, this raises no doubt of its being a larceny; as, where one sent to a hosier's for a quantity of stockings, under pretence of wishing to purchase some, and having selected a part out of a parcel brought by a servant, which he pretended he was going to purchase, under some pretence, sent the servant away, and then decamped with the whole parcel, it was held to be larceny, for the owner had never intrusted him with the parcel, or consented to part with the possession. The same construction was put upon the case, when a servant was sent with some goods to a certain person, and another, pretending to be the person to whom they were sent, received them, with the intent of stealing them. The cases of ring-dropping are instances of it; such getting possession of money or goods by false pretences, being held to be larceny, though the goods come into the possession of the thief by consent of the owner; that is, when a person, in company with another, pretends to find a ring, which was previously dropped for the purpose, and the companion, being imposed upon, proposes to share in the good fortune, to which the finder consents; but not having money, proposes to his companion to take the ring, giving cash, a watch, or something of half the supposed value of the ring, as a pledge, until he can dispose of the ring, when its value is to be equally divided. The transfer having been made, the swindler goes off with the article that he has received, and his companion finds the ring is of little value. This is held to be larceny.

As to the kinds of things, the taking of which is larceny, they must, according to the common law, be personal property, it being a maxim that, though

real estate may be trespassed upon, it cannot be stolen; and so fixtures, and whatever is a part of the *realty*, as it is called, could not be subjects of larceny. Thus it was held that a standing tree, fruit upon the tree, ore in a mine, a fence, lead, brass, or other metal, attached to a building, a copper boiler set in bricks, and whatever else would pass by a conveyance of an estate, was not a subject of larceny, and the taking of such things was only a trespass on the real estate. But this distinction is mostly abolished by statutes, for which there was the stronger reason, as many of these things were such as were peculiarly exposed to be stolen. So, again, by the common law, the feloniously taking of written instruments, they not being considered as property, but merely as evidence of contracts, was held not to be larceny; but this doctrine has been partially abrogated by statutes, and the felonious taking of bonds, bills of exchange, &c., is larceny. As to animals, birds, &c., the felonious taking of domesticated ones is felony; but it is not so with those esteemed to be of a wild nature, as bears, foxes, &c., although they may belong to, or have been purchased by some individual, unless they are tamed, or are in the possession and under the control of some one. The felonious taking of a hive of bees is held to be larceny, unless it be a wild hive in the forest, the taking of which is held not to be larceny. Nothing can be stolen which is not a subject of property; but the crime of larceny is not confined to the depriving the owner of the possession of the article. It is sufficient to constitute the offence, to take the article from the possession of one having only a special property, as a carrier or other bailee; and it is a sufficient allegation of the ownership, in the indictment, to state that the article belonged to such person having a special property. In regard to shrouds and coffins of lead, or other materials of value, the question of ownership has heretofore been made, and they are held to belong to the heirs, executors, or legatees of the person deceased, and it may be so alleged in the indictment.

Larceny was formerly divided in England into two kinds, *grand* and *petty*; the former being the stealing of an article over the value of one shilling, the latter, that of an article not over that value. But this distinction was abolished by a statute of 7 and 8 George IV. In England, the punishment for grand larceny was death; but, most frequently, of late years, it has been commuted for transportation; and, now, the punishment of all simple larceny, of whatever value, is, by the statute above-mentioned, imprisonment or transportation. Great discretion is necessarily left with the court, in regard to the punishment for this offence. Some species of larceny, as from the person, are more severely punished than others, by the English law; and a larceny committed in a dwelling-house, by night, is generally considered an aggravated crime, and is punished accordingly. A severer punishment is awarded, on a second or third conviction of the same offender.

LARCH (*larix*); a genus of plants, included, by many able botanists, together with the spruces, under *pinus*; and, indeed, there seems to be no essential difference in the parts of fructification; the leaves, however, are in separate sheaths, and differ from those both of pines and spruces, in being fasciculate and deciduous. The American larch, or hackmatack, is a noble tree, with a straight trunk, often rising to the height of 100 feet, and giving out numerous slender branches. It is a native of Canada, the northern parts of the United States of America, and the higher regions of the Alleghany mountains. Its southern limit along the sea-coast may be placed at about latitude 41°; but it is not very abundant

even in Vermont, New Hampshire, and Maine. In Canada, according to Michaux, it constitutes extensive masses of forest on the upper parts of the Saguenai, and about lake Mistassini; and it was observed, by major Long, as far westward as lake Winnipeg. The wood, though heavy, is very highly valued, being remarkably strong and durable, and far superior to that of any pine or spruce. In Mass. it is always used for the knees of vessels, where it can be procured. The European larch, a tree very similar in stature and appearance, but having none of double the size, is found throughout Siberia, and in most of the northern and mountainous parts of Europe. It is, however, entirely wanting in Britain and the Pyrenees. The wood is used for a variety of purposes, and is exceedingly durable. An instance is recorded of a vessel built of cypress and larch, which must have remained under water for a thousand years, and the timber of which had become so hard as to resist, entirely, the tools of the workmen. It is much used, in naval architecture, for making the frame-work of vessels, being capable of sustaining much greater pressure even than oak; and in Switzerland, entire houses have been constructed of it, which, however, have the disadvantage of becoming brown, or even black, with age. It affords excellent staves for casks, capable of holding spirituous liquor. The article of commerce called *l'encens turpentine* is obtained from this tree; and a single individual will yield seven or eight pounds annually, for forty or fifty years. The wood, however, is injured by the process. The cedar-like cedar of Lebanon, the largest and most majestic of the *conifera* of the eastern continent, is also a species of larch. Besides mount Lebanon, where the few remaining stocks are preserved with religious veneration, it inhabits Siberia and the Himalaya mountains. The cones are much larger than those of the preceding species. The wood is said to be soft, and of very little value.

LARCHER, PETER HENRY, an eminent French scholar and translator, was born at Dijon, October 12, 1726. He was an intense student of Greek literature, and an assiduous collector of early editions. His first translation was the *Æneid* of Euripides, which attracted little attention; but he became a contributor to several literary journals, and translated from the English the *Mistaken Scribbler*, from Pope's *Miscellanies*, and *See John Pringle's Observations on the Diseases of the Army*. He also wrote notes to the French version of *Robinson Crusoe*. He followed with a translation of the *Comedies* of Chereas and Callirhoe, which was printed in the *Bibliothèque des Romans*. In 1765, a difference took place between him and Voltaire, on whose *Philosophy of History* he published remarks under the title of a Supplement; to which the latter replied in his well known *Défense de son Œuvre*. Larcher rejoined in a *Réponse à la Défense de son Oncle*, with which the controversy closed on his part; but not so with the merciless wit of his opponent. He soon after undertook a translation of Herodotus, and, in 1774, published his *Essai sur l'usage de l'encens*, to which the academy of inscriptions awarded their prize. His translation of Xenophon led to his being elected into that academy. His Herodotus was published in 1786, of which a new and very improved edition appeared in 1802. He was subsequently received into the academy, but finally appointed professor of Greek in the same university, but was too aged for active service. He died December 22, 1812, and was regretted as an accomplished scholar and amiable man.

LARD; the fat of swine, which differs in its constitution from that of almost every other quadruped, as

it covers the animal all over, and forms a thick, distinct, and continued layer betwixt the flesh and the skin, somewhat like the blubber in whales, applicable to various purposes, both culinary and medicinal, and particularly to the composition of ointments. The usual mode of preparation is, to melt it in a jar placed in a kettle of water, and in this state to boil it, and run it into bladders that have been cleaned with great care. The smaller the bladders are, the better the lard will keep. The fat which adheres to the parts connected with the intestines, differs from common lard, and is preferable for the greasing of carriage wheels.

LARDNER, NATHANIEL; a learned divine, born 1684, at Hawkhurst, in Kent. At the age of sixteen, he was sent to the university of Utrecht, and afterwards to that of Leyden. He returned to England in 1703, and commenced a preacher about the age of twenty-five. In 1713, he went to reside in the family of lady Treby, as domestic chaplain, and tutor to her son, whom he afterwards accompanied on a tour through part of France and the Netherlands. In 1723, he was engaged, in conjunction with other ministers, in carrying on a course of lectures at a chapel in the old Jewry, London. In 1727, he published in 2 vols., 8vo, the first part of the *Credibility of the Gospel History*: the twelfth part appeared in 1755, and was followed by three supplementary volumes, comprising a history of the apostles and evangelists, with observations on the New Testament. The university of Aberdeen, in 1745, conferred on him the degree of D. D. In the latter part of his life, he retired to Hawkhurst, where he died, July 24, 1768, at the age of eighty-four. Besides his principal work, he was the author of *Jewish and Heathen Testimonies to the Truth of the Christian Religion* (1764—67, 4 vols., 4to); the *History of the Heretics of the two first Centuries* (4to, 1780); a *Vindication of three of our Saviour's Miracles*, and other theological compositions. A collective edition of his works, with his life by doctor Kippis, was published in 1788 (11 vols., 8vo.)

LARES (*familiares*) were the domestic and family tutelary gods among the Romans. They were images of wood, stone and metal, and generally stood upon the hearth in a kind of shrine (*lararium*). The higher classes had them also in their bedchambers or private *lararia* (domestic chapels). On important occasions, a young pig, a lamb, or a calf, was sacrificed to them. From these domestic *lares* must be distinguished those which were publicly worshipped by the whole state, by a city or class of men. Silvanus was the general *lar* of the peasants, and Mars of the soldiery. The public *lares* were twin sons of Mercury and the nymph Lara. At Rome, in the beginning of May, a festival was solemnized in honour of them, and of the reigning emperor, who was considered a public *lar*. See *Penates*.

LARISSA, a city of Thessaly, on the Peneus, celebrated in ancient times for its bull-fights, which were conducted in the same manner as they are at present in Madrid, was the rendezvous place of Julius Cæsar's army before the battle of Pharsalia. It is now the largest, richest, and most populous city in Thessaly, and the seat of a Greek archbishopric, with 4000 houses, and 25,000 inhabitants, of whom about one fourth are Greeks. It has houses for dyeing, manufactures of morocco leather, considerable commerce, and some attention is paid to the cultivation of the vine. It was the head-quarters and centre of the military operations of the Turks against the Greeks from the time of Ali Pacha, who laid the foundation of his power in Larissa. From this city Ali, Kourschid Pacha, and all the other seraskiers who succeeded him, commenced their campaigns against Livadin and Epirus.

LARIVE, J. MAUDUIT DE, one of the most distinguished tragic actors of France, after Lekain and Talma, was born in 1749, at La Rochelle. Having made his *début* in Lyons, he appeared in Paris, in 1771. He was particularly distinguished in heroic parts. During the reign of terror, he was arrested, and saved only by a secretary of the committee of public safety, who destroyed the proofs against him and the other actors. Before new documents could be collected, Robespierre was overthrown. Geoffroy's *critiques*, and Talma's rising fame induced him to leave the stage rather early. He bought a country-seat in the valley of Montmorency, and was elected mayor of the place. In 1806, he went, for a short time, to the court of Joseph Bonaparte then king of Naples, to establish a French theatre in his capital. In 1816, he appeared once more in the part of Tancred, though sixty-seven years old, for a charitable purpose, with great success. Larive died in 1822. Of his several works, the most important is his *Cours de Déclamation* (3 vols., Paris, 1804—1810).

LARK (*alauda*). In this genus of birds, the bill is straight, slender, bending a little towards the end, and sharp-pointed; the nostrils are covered with feathers, and the tongue bifid. The toes are free, the hinder one thickest, and nearly equal to the outer. There are several species which deserve notice.

The sky-lark (*A. arvensis*), which is the most harmonious of this musical family, is almost universally diffused throughout Europe, is every where extremely prolific, and sought for. These birds are easily tamed, and become so familiar as to eat from the hand. The sky-lark commences his song early in the spring, and continues it during the whole summer, and is one of those few birds that chant whilst on the wing. When it first rises from the earth, its notes are feeble and interrupted; as it ascends, however, they gradually swell to their full tone, and, long after the bird has reached a height where it is lost to the eye, it still continues to charm the ear with its melody. It mounts almost perpendicularly, and by successive springs, and descends in an oblique direction, unless threatened with danger, when it drops like a stone. The female forms her nest on the ground, generally between two clods of earth, and lines it with dry grass. She lays four or five eggs, which are hatched in about a fortnight, and she generally produces two broods in the year. In the autumn, when these birds assemble in flocks, they are taken in vast numbers. Pennant states that as many as 4000 dozen have been caught near Dunstable alone.

The wood-lark (*A. arborea*) is distinguished by its small size and less distinct colours. It is generally found near the borders of woods, perches on trees, and sings during the night, so as sometimes to be mistaken for the nightingale. When kept in a cage, near one of the latter birds, it often strives to excel it, and, if not speedily removed, will fall a victim to emulation. The female lays five eggs, of a dusky colour, interspersed with deep brown spots, and like the former species, raises two broods in the year.

There is but one true lark, the shore-lark (*A. alpestris*), found in America, and this is also an inhabitant of Europe, though it is much more common, and migrates farther south, in America. It is of a reddish drab colour, with a whitish tint beneath; a broad patch on the breast and under each eye, as well as the lateral tail feathers black.

The brown lark of Wilson properly belongs to the genus *anthus*. This bird, however, possesses many of the habits of the lark, as that of singing when rising on the wing, seldom perching on trees, building on the ground, &c. The brown lark is also an

inhabitant of both continents. It is of a pale rufous colour beneath, with the breast spotted with black; tail feathers blackish, the outer half white; the second, white at tip. It is usually found in open fields, cultivated grounds, &c., near the water, and feeds exclusively on insects.

The meadow-lark, which Wilson classed with the *alauda*, does not belong to this genus, being a *sturnus*, or rather a *sturnella* (Viell), a genus somewhat allied to *alauda*. See *Meadow-Lark*.

**LARKSPUR** (*delphinium*); a genus of plants allied to the ranunculus and columbine, distinguished by its petaloid calyx, the superior leaflet of which terminates in a long spur. The stem is herbaceous, bearing alternate leaves, which are usually very much divided; and the flowers are disposed in terminal racemes. Some of the species are common in our gardens, where they are cultivated for the beauty and brilliant colours of their flowers, the prevailing tint of which is blue. Fifty species are known, all belonging to the northern hemisphere, and most of them to the regions around the Mediterranean and Black seas. Few only inhabit North America.

**LAROCHE-JACQUELIN**. See *Roche Jacquelin*, and *La Vendée*.

**LA ROMANA**, MARQUIS DE. See *Romana*.

**LARTA**. See *Arta*.

**LARVÆ**; a name given to evil spirits and apparitions, which, according to the notions of the Romans, issued from their graves in the night, and came to terrify the world. The word properly signifies a *mask*, whose horrid and uncouth appearance serves to frighten children. See *Lemures*.

**LASCARIS**; the name of two noble Greeks of the fifteenth century, descendants of the imperial family, and both natives of Constantinople, who, on the taking of that capital by the Turks, in 1453, fled to Italy.

*Constantine*, the elder, settled first at Milan, where he was received into the grand-duke's household, as tutor to his daughter. He afterwards visited Rome and Naples, in which latter city he opened a school of eloquence, and, finally, took up his abode at Messina, whither the fame of his literary attainments, especially in the Greek language, attracted many distinguished disciples, and, among others, the celebrated Pietro Bembo, afterwards known as the cardinal of that name. He was the author of a Greek Grammar, and of some other works in that language and in Latin, which were first printed at Milan, in 1476, and again at Venice, in 1495, at the Aldine press. He died about the close of the century.

*John*, the younger of the two, surnamed *Rhyndacenus*, took up his residence at Padua, under the protection of Lorenzo de' Medici, who distinguished him by his favour, and despatched him into Greece, to purchase valuable manuscripts. The sultan's orders gained him access to the libraries, so that he accomplished his mission much to the satisfaction of his employer, and enriched the Florentine collection with the fruits of his researches. In 1494, he quitted Italy, and entered the service of Louis XII. of France, who made him his envoy to the Venetian senate; but, on the elevation of John de' Medici to the papedom, by the title of Leo X., Lascaris went to Rome, at the invitation of that pontiff, and, on the foundation of his Greek college there, was appointed its first principal, and superintendent of the Greek press. To promote the ends of this institution, of which the ascertaining and preserving the true pronunciation of the Greek language was one of the chief, Lascaris made a second journey into Greece, and brought back with him some youths of good families, who were to communicate and receive instruction. The remainder of his life was divided

between Paris, where he assisted Francis I. in forming the royal library, and Rome, in which latter city he died of the gout, at the age of ninety, in 1536. He published a translation of Polybius and of the Argonautics of Apollonius, together with a *Greek Anthology* (1494, folio); annotations on the works of Sophocles and Homer; four of the plays of Euripides, and a collection of epigrams and apophthegms in Greek and Latin (Paris, 4to, 1527).

**LASCARS**; native Indian sailors, many of whom are in the service of the East India company.

**LAS CASAS**. See *Casas*.

**LASCY**, PIERRE, count de; a military officer, born in Ireland, in 1678. After the conquest of Ireland by William III., he entered the French service. After the peace of Ryswick, he entered into the Austrian army and served against the Turks. He was first employed by the king of Poland, and then by Peter the Great of Russia. In 1709, he was wounded at Pultowa; and he assisted in the taking of Rapa, of which he was made governor. He was made a lieutenant-general in 1720. Catharine I. appointed him governor of Livonia. He died in 1751, having attained the rank of field-marshal. The prince de Ligne published a collection of the works, and a journal of the campaigns, of marshal Lascy.

**LASCY**, JOSEPH FRANCIS MARIACE, count de, one of the foregoing, was born at Petersburg in 1722. In 1744, he entered into the Austrian service, and made a campaign in Italy. He gradually rose to the rank of general, after having displayed his military talents at the battles of Lowositz, Breun, and Hochkirchen; and, in 1760, he penetrated to Berlin, at the head of 15,000 men; for which bold exploit, he was made a commander of the order of Maria Theresa, and, in 1762 received the baton of marshal. Under Joseph II., he was a member of the council of war at Vienna, and was the author of the military regulations adopted by that prince. He was employed against the Turks in 1788, and again after the death of Laudohn. He died at Vienna, November 30, 1801.

**LASHER** (*cottus scorpius*); a formidable-looking and singular fish, belonging to the great order of *acanthopterygiens* (Cuvier). It is about half a foot long, having the head and anterior part much larger in proportion than the posterior. The head is blackish, the black variegated with pale and black patches, placed transversely; sides divided by a rough longitudinal line, below which they are yellow, becoming whiter as they approach the belly. The gill-covers and head are furnished with formidable spines, which are capable of inflicting a painful wound, which circumstances appears to have been well known to the ancients: "*Et capitis duntaxat scorpius scitu*." This fish has the faculty of swelling out its gill-covers and cheeks to an enormous size. It is found in all parts of the southern Atlantic ocean, being very frequent about Newfoundland and the Eastern States, where it is called *sculpin*. In Greenland, it forms a favourite article of food.

**LASSA**; a city of Asia, the capital of Goozistan. It is little known to Europeans. It is chiefly distinguished as the residence of the Dala-han, or the great head of the Shaman religion. *Monges* &c. are usually crowded with royal and noble personages, from all parts of Asia, who come to present their homage, and to offer splendid presents to the earthly divinity. Lon. 91° 6' E.; lat. 33° 35' N. See *Lama*.

**LASSO**, ORLANDO DI (Orlando Lassus); one of the greatest musicians of the sixteenth century. He was born at Mons, in Hainaut, in 1530. Thomas (De Thou) relates that he was carried with some o-

child, on account of his fine voice. Ferd. Gonsaga, viceroy of Sicily, took him to Italy and had him instructed in music. Having lost his voice in his eighteenth year, he was occupied three years in Naples as a teacher of music. He then became chapel-master in the Lateran church in Rome. Here he remained two years, and then returned to his native country to see his parents, whom, however, he did not find living. He then travelled, with Julius Cæsar Brancaccio, to England and France, and again lived, for some years, in Antwerp, whence he went to Munich as chapel-master to Albert duke of Bavaria. Charles IX. of France invited him to Paris; but Lasso learned, on his way to that city, the death of the king, and was immediately re-established in his place by duke William. He remained in this office till his death. Orlando was equally celebrated for his sacred and his secular music. He was the improver of figured counterpoint. His productions were numerous, but are, at present, rarely to be met with. His sons published a collection of his *motets* under the name *Magnum Opus Musicum* (Munich, 1604, 17 volumes, folio). In the royal library at Munich, is the richest collection of his works.

LATAKIA (anciently *Laodicea*); a seaport in Syria, fifty miles south Antioch, seventy south-west Aleppo, lon. 35° 44' E.; lat. 35° 32' N.; population, in 1810, about 10,000; since reduced to 4000. It is a Greek bishop's see. It is situated at the base, and on the south side of a small peninsula, which projects half a league into the sea. Its port, like all the others on this coast, is a sort of basin, environed by a mole, the entrance of which is very narrow. It might contain twenty-five or thirty vessels, but the Turks have suffered it to be so choked up as scarcely to admit four. Ships of above 400 tons cannot ride there, and hardly a year passes, that one is not stranded in the entrance. Notwithstanding this, Latakia carries on a great commerce, consisting chiefly of tobacco, of which upwards of twenty cargoes are annually sent to Damietta. The returns from thence are rice, which is bartered, in Upper Syria, for oil and cottons. This place is subject to violent earthquakes. One, in 1796, destroyed a great part of the city, and 2000 of the inhabitants; another, in 1822, overthrew a third of the buildings.

LATERAN; a square in Rome, so called from an ancient Roman family of the same name. Nero put to death the last possessor, Plautius Lateranus, and seized his estates. Thus the Lateran palace became the property of the emperor. Constantine the Great gave it to the popes, who occupied it for 1000 years, till the removal of their residence from Rome to Avignon. The church of St John of Lateran, connected with this palace, was built by Constantine. It is the episcopal church of the pope, and the principal church of Rome; hence the inscription over the principal door—"Omnium urbis et orbis ecclesiarum mater et caput" (the mother and head of all the churches of the city and the world). It is also called *Lateran*. Its great antiquity, the recollection of seven councils which have been held in it, the rare relics which are preserved in it, and its splendid architecture, render this church particularly worthy of veneration. At the portal is the balcony, from which the pope bestows his blessing upon the people. The chief altar of this church, none but the pope can read mass; for within it is a wooden one of great antiquity, upon which the apostle Peter is said to have read mass. In this church, also, are to be seen two stools of red marble, which have an opening in the middle of the seat, and which are said to have been used for the investigation of the sex of the newly created pope; but, in the baths of Caracalla, where they were found, they were probably put to an entirely

different use. At the present time, every newly elected pope takes solemn possession of this church, accompanied by a cavalcade. Upon the Lateran Place stands a chapel, to which belongs the *Scala santa* (a staircase of twenty-eight steps, which is said to have come from the house of Pilate, and which believers ascend on their knees), and the chapel of *San Giovanni in Fonte*, built by the emperor Constantine, the cupola of which consists of eight porphyry pillars, considered the most beautiful in Rome.

LATE WAKE; a ceremony formerly used at funerals, in some parts of the Highlands of Scotland. The evening after the death of any person, the relations and friends of the deceased met at the house, attended by a bagpipe or fiddle. The nearest of kin, wife, son or daughter, opened a melancholy ball, dancing and *greeting* (i. e. crying violently) at the same time, and this continued till daylight; but with gambols and frolics, among the younger part of the company. If the corpse remained unburied for two nights, the same rites were renewed. An anecdote is told of a disconsolate widow, who, on the opening of the ball, being asked by the piper what tune he should play, said, "Oh, mak it a light spring (lively tune), for my heart is heavy."

LATIMER, HUGH, an eminent English prelate and reformer in the sixteenth century, was the son of a respectable yeoman at Thurcaston, in Leicestershire, where he was born about the year 1470. He received his early education at a country school, whence he was removed to Cambridge in his fourteenth year. He first became openly obnoxious to the enemies of innovation, by a series of discourses, in which he dwelt upon the uncertainty of tradition, the vanity of works of supererogation, and the pride and usurpation of the Roman hierarchy. At length, the bishop of Ely interdicted his preaching within the jurisdiction of the university; but doctor Barnes, prior of the Augustines, being friendly to the reformation, licensed Latimer to preach in his chapel, which was exempt from episcopal interference. The progress of the new opinions was represented to cardinal Wolsey, who, at the importunity of archbishop Warham, created a court of bishops and deacons to put the laws in execution against heretics. Before this court, Bilney, and Latimer were summoned, and the former, who was deemed the principal, being induced to recant, the whole were set at liberty; and Latimer was licensed, by the bishop of London, to preach throughout England. Bilney afterwards disclaimed his abjuration, and suffered martyrdom at Norwich. The fate of his friend by no means intimidated Latimer, who had the courage to write a letter of remonstrance to Henry VIII., on the evil of prohibiting the use of the Bible in English. Although this epistle produced no effect, Henry presented the writer to the living of West Kinton, in Wiltshire. The ascendancy of Anne Boleyn, and rise of Thomas Cromwell, proved favourable to Latimer, and he was, in 1535, appointed bishop of Worcester. It was then the custom for bishops to make presents, on new-year's day, to the king, and, among the rest, Latimer waited at court with his gift, which, instead of a purse of gold, was a New Testament, having the leaf turned down to this passage—"Whoremongers and adulterers God will judge." Henry was not, however, offended; and, when the sturdy prelate was, some time after, called before him to answer for some passages in a sermon which he had preached at court, he defended himself so honestly, that he was dismissed with a smile. The fall of Anne Boleyn and Cromwell prepared the way for reverses, and the six articles being carried in parliament, Latimer resigned his bishopric, rather

than hold any office in a church which enforced such terms of communion, and retired into the country. Here he remained in privacy, until obliged to repair to London for medical advice. There he was discovered by the emissaries of Gardiner, and imprisoned for the remainder of Henry's reign. On the accession of Edward, he was released, and became highly popular at court by his preaching, during that reign, but never could be induced to resume his episcopal functions. He took up his abode with archbishop Cranmer at Lambeth, where his chief employment was to hear complaints and procure redress for the poor. Soon after Mary ascended the throne, Latimer was cited to appear before the council, in doing which, an opportunity was afforded him to quit the kingdom. He, however, prepared with alacrity to obey the citation, and, as he passed through Smithfield, exclaimed, "This place has long groaned for me." About the same time, Cranmer and bishop Ridley were also committed to the Tower, and the three prelates were confined in the same room. From the Tower they were conveyed to Oxford, and confined in the common prison, preparatory to a disputation, in which Latimer behaved with intrepidity and simplicity, refusing to deliver any thing more than a free confession of his opinions. The three prelates, although condemned, remained in prison sixteen months, chiefly because the statutes under which they had been tried had been formally repealed. In 1555, however, new and more sanguinary laws having been enacted, in support of the Roman religion, a commission was issued by cardinal Pole, the pope's legate, to try Latimer and Ridley for heresy. Much pains were taken, during this second trial, to induce them to sign articles of subscription, which they steadfastly refused, and were, in consequence, delivered over to the secular arm, and condemned to the flames. This sentence was put in execution about a fortnight after their condemnation, Oct. 16, 1555. At the place of execution, having thrown off the old gown which was wrapped about him, Latimer appeared in a shroud, prepared for the purpose, and, with his fellow-sufferer, was fastened to the stake with an iron chain. A fagot, ready kindled, was then placed at Ridley's feet, to whom Latimer exclaimed, "Be of good comfort, master Ridley, and play the man. We shall this day light such a candle, by God's grace, in England, as, I trust, shall never be put out." He then recommended his soul to God, and, with firmness and composure, expired. His preaching was popular in his own times, in which his simplicity, familiarity, and drollery were highly estimated.

**LATIN EMPIRE.** See *Byzantine Empire*.

**LATIN LANGUAGE.** See *Roman Language and Literature*.

**LATINS** (*Latini*); an ancient people of Latium in Italy, who sprang from a mixture of the aborigines with Arcadian-Pelasgian and Trojan colonists. The derivation of their name is unknown. It is not probable that they received it from king Latinus. Janus, Saturn, Picus, and Faunus, who were deified by their subjects, are represented to have been the most ancient Latin kings. These names were probably appellations of the old Pelasgian divinities. During the reign of Faunus, Hercules and Evander are said to have arrived in Latium; the latter taught the aborigines the use of the alphabet, music, and other arts, and also succeeded Faunus in the government. About sixty years afterwards lived king Latinus, at whose court Æneas (q. v.) arrived, married his daughter Lavinia, and succeeded to his throne. The city of Alba Longa was built by Ascanius, the son of Æneas by a former marriage, and made the seat of the Latin kings. Henceforward we know nothing

of the history of Latium, whose kings all bore the surname of *Sylvius*, until Romulus and Remus laid the foundations of a new city. Jealousy kindled a war between these two sister states, the Latin and the Roman, which terminated with the subjugation of the Latins and the demolition of their capital. Rome became the capital of all Latium, where king Servius united the Latins with the Romans in a permanent confederacy. From this epoch, we may date the beginning of the greatness and splendour of Rome; for, without the valour and friendship of the Latins, she would never have obtained the dominion of the world. Tarquinius Superbus endeavoured to draw this alliance still closer; but, after his banishment, he excited the Latins to rise against Rome. This war of the Romans with the Latins, the first since the alliance which had been made between them, was decided in favour of Rome by the valor of the dictator, and the treaty was renewed. In the year of Rome 414, there was a still more dangerous rupture between them. The Latins made war upon the Samnites, who implored the assistance of the Romans. A dispute arose between Rome and Latium, in which the latter went so far as to demand that one consul and half of the senate should be Latins. This demand was indignantly rejected by the Romans, and, in the war which followed, the Latins were reduced after a very severe struggle. When the Romans had nearly obtained the dominion of the world, the Latins made another attempt to regain their freedom, by engaging in the Social war (A. U. C. 663), and they succeeded so far as to recover many of their privileges. (See *Rome and Latium*.) Niebuhr's History of Rome (introduction chapter) contains a critical examination of the acts of the Latins.

**LATINUS**; a son of Faunus by Marica. He was king of the aborigines in Italy. He married Anula, by whom he had a son and a daughter. The son died in his infancy, and the daughter, called Lavinia, was secretly promised in marriage, by her mother, to Turnus, king of the Rutuli, one of her most powerful admirers. The gods opposed this union, and the oracle declared that Lavinia must become the wife of a foreign prince. The arrival of Æneas in Italy seemed favourable to this prediction, and Latium, by offering his daughter to the foreign prince, and making him his friend and ally, seemed to have fulfilled the commands of the oracle. Turnus, however, disapproved of the conduct of Latium; he claimed Lavinia as his lawful wife, and prepared to support his cause by arms. Æneas took up arms in his own defence, and Latium was the seat of the war. After mutual losses, it was agreed that the quarrel should be decided by a combat between the two rivals, and Latinus promised his daughter to the conqueror. Æneas obtained the victory, and married Lavinia. Latinus soon after died, and was succeeded by his son-in-law. This is the form of the legend in the *Æneid*; other accounts are different.

**LATITUDE**, GEOGRAPHICAL; the distance of a place, on the surface of the earth, from the equator, measured by that arc of the meridian of the place which is intercepted between the place and the equator. Geographical latitude is either north or south, according as the place, reckoned from the equator of the earth, lies towards the north or the south pole. Latitude is the measure of the angle formed by a vertical line drawn from the place to the centre of the earth and the plane of the equator. Since, however, this vertical line, if continued to the heavens, passes through the zenith of that place, and the plane of the terrestrial equator, continued to the heavens, meets the celestial equator, the latitude of a place is also determined by the distance between

the celestial equator and the zenith, or, in other words, by the complement of the altitude of the equator; and, as the complement of the altitude of the equator is the altitude of the pole, the latitude of a place is equal to the altitude of the pole at that place. Places situated in the equator itself have neither latitude nor altitude, because their two poles lie in the horizon. Nor can the latitude of a place be more than 90°, because the altitude can never exceed 90°, that is to say, because the pole, at the most, can only be in the zenith itself. Latitudes, together with longitudes (q. v.), serve to fix the situation of places on the globe, and their distance from each other. The determination of local positions is the foundation of geography, and of the correct projection of maps.—In astronomy, *latitude* is used to signify the distance of a heavenly body from the ecliptic, which distance is measured by the arc of a great circle (circle of latitude), perpendicular to the ecliptic, which is intercepted between the ecliptic and the body. Here, also, latitude is north and south. A heavenly body in the ecliptic has no latitude, for which reason the sun has no latitude, and that of the planets is very small. The latitude of a heavenly body can never exceed 90°. It is determined by the right ascension and declination. The latitude of stars is laid down in the list of the fixed stars. An extensive list of the geographical latitudes of places is contained in the Berlin Collection of Astronomical Tables, vol. i. p. 43, et seq.

*Heliocentric latitude of a planet*, is its latitude or distance from the ecliptic, such as it would appear from the sun. This, when the planet comes to the same point of its orbit, is always the same, or unchangeable.

*Geocentric latitude of a planet*, is its latitude as seen from the earth. This, though the planet be in the same point of its orbit, is not always the same, but alters according to the position of the earth in respect to the planet. The latitude of a star is altered only by the aberration of light, and the secular variation of latitude.

LATITUDINARIAN, among divines, denotes a person of moderation with regard to religious opinions, in contradistinction to the rigid adherents to particular doctrines. This name was first given, by way of distinction, to those excellent persons, in England, who, about the middle and towards the close of the seventeenth century, endeavoured to allay the contests that prevailed between the more violent Episcopalians on the one hand, and the more rigid Presbyterians and Independents on the other, and also between the Arminians and Calvinists. At present, it generally denotes one who departs, in opinion, from the strict principles of orthodoxy.

LATIUM; the principal country of ancient Italy, and the residence of the Latins. The limits, which appear to have been changed at different periods, are generally represented to be the Tiber on the north, and the promontory of Circeii (Monte Circello) on the south; but this is probably too extensive. According to Strabo, there were, besides the Latins, Rutuli, Volsci, Hernici, and Æqui in this region. The actual extent of Latium, at the time of the building of Rome, may have amounted, at the most, to about forty-six miles in diameter, and the actual boundaries were probably the Tiber on the west, the Anio on the north, mount Algidum on the east, and, on the south, the city of Ardea, which was situated at the distance of 160 stadia from Rome. Latium afterwards extended to the river Liris (Garigliano), but the northern and eastern boundaries remained the same. In the earliest times, there was a large aul grove situated on the coast, at the mouth of the Tiber, which extended as far as the city of Lau-

rentum. This grove not only gave the name to the city, but also to the surrounding country, which was hence called *Laurentinus ager*, and the inhabitants were styled *Laurentes*. This grove is said to have been standing in the time of the emperor Commodus. Between the Tiber and the city of Laurentum was the place where Æneas pitched his camp, which bore the name of Troy. To the eastward of this place, twenty-four stadia from the Tiber, was the city of Laurentum. Farther on, lay the little river Numicus and the sources of the Juturna; and still farther to the east, was situated the city of Lavinium. Beyond the sources of the Numicus and the Juturna, was the mountain upon which, thirty years after the building of Lavinium, was placed the city of Alba Longa. Behind this, towards the Hernici, lay Aricia; still farther above, in the extreme north-easterly corner of Latium, was the city of Præneste; towards the northern extremity of the same province, was the city of Tibur, and between these two cities and Rome, were Gabii and Tusculum. All these cities were colonies of Alba Longa. The first colony of the Romans was Ostia, established by Ancus Martius, below Rome. In the time of the Romans, Latium was very thinly inhabited; and, 100 years after the building of Rome, complaints began to be made on account of the desolation of the country and its unhealthy atmosphere. With the enormous wealth which the Romans acquired from the conquest of Greece and Asia, villas, which contained great numbers of slaves, were built in this desolate region, and the air was thus rendered somewhat healthier. In this way cities and villages sprang up around Rome, which were afterwards deserted and destroyed. The rivers of Latium were the Tiber, the Liris, the Anio, Numicus, Ufens, Amasenus, and Almo. The Ufens flowed through the Pontine marshes. These marshes were known from the earliest times, and extended between the rivers Ufens and Nymphæus to a great distance. There were also some lakes in Latium, of which lake Regillus was the principal. The mountains of this province were, with few exceptions (as, for example, the Alban mountain and mount Algidum) merely hills. For a minute description of this region, see the *Description of Latium*, with twenty engravings; and a map of the Campagna di Roma, London, quarto; and Cramer's *Description of Ancient Italy*, Oxford, 1826.

The Latin right (*jus Latii*) originally belonged to the Latin allies of Rome, but was afterwards extended to some other states on their accession to the alliance. The members of these states were not enrolled among the Roman citizens, but had a census of their own. They were required to raise auxiliary troops, which did not serve in the Roman legion, but as a separate force. They had the right of voting at Rome, but under certain limitations, and they elected their own magistrates. All who enjoyed neither the Roman citizenship (*civitas Romana*), nor the Latin right, were called *foreigners* (*peregrini*).

LATONA (by the Greeks called Λατονα, in the Doric dialect Λατονα), daughter of Cæus and Phœbe (according to some, of Saturn), became the mother of Apollo and Diana by Jupiter. During her pregnancy, she was persecuted by Juno, by whose command the dragon Pytho threatened her everywhere with death and ruin, and the earth was not permitted to allow her a place for her delivery. After long wanderings, she found rest on the island of Delos (q. v.), which rose from the sea to receive her. The giant Tityus, having attempted to offer her violence, was killed by Apollo and Diana. According to another fable, this giant was struck dead by Jupiter, with lightning, before her pregnancy. Jupiter changed too some Lycian peasants into frogs, because they would not permit her

to drink, on her flight from Delos, from which Juno had again driven her (Ovid's *Metam.* vi. 4). Latona is represented as a mild, benevolent goddess, in a sea-green dress. With Diana she cured the wounded Æneas, and crowned him with glory. When Diana fled to Olympus, from the anger of Juno, Latona carried to her her quiver and arrows, which she had left behind. Latona was worshipped chiefly in Lycia, Delos, Athens, and other cities of Greece. In Crete, a festival was celebrated in honour of her, called *Ecdysia*. She is sometimes considered as the symbol of night, because the sun proceeds, as it were, from the night. Hence, also, some derive her name from the Greek *latanois* (to hide).

**LATOUR D'AUVERGNE-CORRET**, **THEOPHILUS DE**, one of the bravest soldiers mentioned in military history, was born in 1743, at Carhaix, in the department of Finisterre (Brittany), early decided to become a soldier, and was aid-de-camp to the duke De Crillon at the siege of Mahon. When the revolution broke out, he was among the first to rally round its standard, and distinguished himself among 8000 grenadiers, in the army of the Pyrenees. Higher appointments were offered to him, but he always declined, declaring that he was only fit to command a company of grenadiers. His corps generally made the van-guard, and was called the *infernal column*. After the peace of Bale, he fell into the hands of the British, and was a prisoner a year in England. After his exchange, he occupied himself with literary labours, and, in 1799, again bore arms instead of a son of his friend Lebrigard, fought under Massena, in Switzerland, and fell at Neuburg, in 1800, while attached to the army of the Rhine, having been, not long before, named first grenadier of France by the first consul. A monument was erected on the spot where he fell. His heart was embalmed, and carried, in a silver box, by one of the company in which he had served. His name was always called, and the bravest grenadier answered—"Died on the field of honour." As an author, he made himself known by a singular work on the early history of Brittany.

**LATROBITE**; a mineral named after the reverend C. I. Latrobe. It is found massive and crystallized; but the crystals not well defined; colour, pale pink; scratches glass; specific gravity, 28. It is composed of

Silex, . . . . .	44.65
Alumina, . . . . .	38.21
Lime, . . . . .	8.29
Potash, . . . . .	6.57
Oxide of manganese, . . . . .	3.16

It is found at Amitok island, near the coast of Labrador, and is accompanied by mica and carbonate of lime.

**LATTAIGNANT**, **GABRIEL CHARLES**, abbé de, a poet, the memory of whose songs has not yet perished in France, and who rendered himself known by the popular opera *Fanchon*, was born in Paris, towards the end of the seventeenth century. He was canon at Rheims, and counsellor of the parliament of Paris, but united great gaiety with his serious occupations. After having taken part in all the pleasures of life, he retired to a monastery, and died 1779. His poems were published in four volumes, 12mo., which were followed, after his death, by his songs and writings not before printed.

**LATUDE**, **HENRI MAZERS DE**, born in 1724, at Montagnac, in Languedoc, was imprisoned, when twenty years old, in the Bastille, in the reign of Louis XV., because, in order to gain the favour of Madame de Pompadour, he had persuaded her that an attempt was to be made on her life, by a box containing the most subtle poison. The box actually arrived, but contained nothing but ashes, sent by Latude himself.

His repeated attempts to escape rendered his confinement more rigorous, and he remained in prison thirty-five years. He was delivered from his confinement in 1779. He then wrote his memoirs, which became a formidable weapon in the hands of the revolutionary party. The national assembly decreed him a pension, which was afterwards, however, withdrawn. The heirs of Amelot and Madame de Pompadour were sentenced to make him indemnification. He died in 1804, eighty years old.

**LAUD**, **WILLIAM**, archbishop of Canterbury, in the reign of Charles I., was born at Reading, in Berkshire, in 1573, and received his education at John's college, Oxford, of which he became a fellow in 1593. He took priest's orders in 1601, and, the following year, preached a divinity lecture, in which he maintained the perpetual visibility of the church of Rome until the reformation, which doctrine being disapproved by doctor Abbot, master of University college, the foundation of that animosity was laid, which ever after subsisted between them. In 1608, he was made chaplain to Neile, bishop of Rochester, who gave him the rectory of Cuckstone, in Kent, and he soon after preached his first sermon before James I. In 1611, he became president of his college, and one of the king's chaplains, and, in 1617, accompanied James I. to Scotland, to aid him in his attempt to bring the church of Scotland to a conformity with that of England. In 1620, he was installed a prebend of Westminster, and, the next year, nominated to the see of St David's. About this time, James took upon himself to interdict the introduction into the pulpit of the doctrines of predestination, election, the irresistibility of free grace, or of any matter relative to the powers, prerogatives, and sovereignty of foreign princes. These measures being attributed to the counsels of bishop Laud, the Calvinistic or Puritanic party were much incensed at his conduct. On the accession of Charles I., Laud's influence, by the countenance of Buckingham, became very great; and he was ordered to furnish the king with a list of all the divines in the kingdom, against whose names he marked O. or P., to signify Orthodox or Puritan. In 1626, he was translated to the see of Bath and Wells, and, in 1628, to that of London. On the sequestration of archbishop Abbot, in consequence of having accidentally shot a game-keeper, Laud was appointed one of the commissioners for exercising the archiepiscopal jurisdiction, and, being a zealous supporter of the hated administration of Buckingham, became in the highest degree unpopular. On the assassination of that favourite by Felton, bishop Laud, suspecting that some member of parliament might be privy to the deed, prevailed on the king to send to the judges for their opinion, "whether, by law, Felton might not be ratched?" Bishop Laud was also the most active member of the high commission court, the arbitrary and oppressive proceedings of which were so justly odious to the nation. In 1630, he was elected chancellor of the university of Oxford, to which he was a great benefactor, and which he enriched with an invaluable collection of manuscripts, in a great number of languages, ancient, modern, and Oriental. In 1633, he attended Charles into Scotland, who went there to be crowned; and, on his return, he was promoted to the see of Canterbury, become vacant by the death of archbishop Abbot. On the same day, an agent from the court of Rome came to him personally, and offered him a cardinal's hat—a fact which shows how strongly he was suspected of a pretension for the church of Rome. He, however, declined the proposal, feeling, as he expresses himself in his diary, "That something devilish within him which would not suffer that till Rome were other

than it is." In 1634, he commenced a metropolitan visitation, in which the rigour of his proceedings, to produce conformity, was exceedingly unpopular. In 1635, he was appointed one of the commissioners of the treasury, in which situation he remained a year. The prosecution of Prynne, Burton, and Bastwick, for libel, took place in 1632, the odium of which, and the severe sentences that followed, rested principally upon him. In 1637, he procured a decree of the star-chamber, limiting the number of printers, and forbidding the printing of any book not licensed by the bishop of London or archbishop of Canterbury, for the time being, or by the chancellor or vice-chancellor of the universities. Catalogues of all books from abroad were also to be furnished to the same authorities; and so arbitrary was the conduct of Charles's ministers, at this period, that numbers, both of the clergy and laity, sought to quit the country. A proclamation was issued to restrain them, unless certificated to be conformable to the discipline of the church. After a lapse of twelve years, a parliament was convened in April, 1640; the commons commenced by appointing committees of religion and grievances, on which it was suddenly dissolved, after sitting only three weeks. All sorts of means were then put in force to raise supplies, by loan, benevolence, ship-money, &c., those who refused payment being fined and imprisoned by the star-chamber or council-table. A clerical convocation was also authorised by the king, to sit, independent of the parliament. This body, besides granting subsidies, prepared a collection of constitutions and canons ecclesiastical, which, being approved by the privy council, was made public, and gave such general disgust to the moderate of all parties, and produced so great a number of petitions to the privy council, that Charles was obliged to suspend them. On the calling of the long parliament, the new canons were summarily disposed of, as subversive, both of the rights of parliament, and of the liberties and property of the subject, and the long gathering storm immediately burst over the head of the archbishop. The next day, articles presented against him by the Scottish commissioners were read in the house of lords, which when referred to the commons, a motion was put and carried, that he had been guilty of high treason. The celebrated Denzil Holles was immediately sent to the house of lords, to impeach him in the name of all the commons of England, and he was delivered into the custody of the black rod. Feb. 26, 1641, fourteen articles of impeachment were brought up from the commons, and he was committed to the Tower. Soon after his commitment, the house of commons ordered him, jointly with those who had passed sentence against Prynne, Bastwick, and Burton, to make them satisfaction for the damages which they had sustained by their sentence and imprisonment. He was also fined £20,000 for his proceedings in the imposition of the canons, and was otherwise treated with extreme severity. He remained in prison three years before he was brought to trial, which at length, on the production of ten additional articles, took place March 12, 1644, and lasted twenty days. Many of the charges against him were insignificant and poorly supported; but it appeared that he was guilty of many arbitrary, illegal, and cruel actions. His own defence was acute and able; and his argument—that he could not be justly made responsible for the actions of the whole council—if not absolutely a legal, was a strong moral defence. The lords were still more staggered by his counsel showing that, if even guilty of these acts, they amounted not to high treason. A case was made for the judges, who very much questioned if they were so, and the peers deferred giving judgment.

On this delay, the house of commons passed a bill of attainder, Jan. 4, 1644—45, in a thin house, in which the archbishop was declared guilty of high treason, and condemned to suffer death—as unjustifiable a step, in a constitutional point of view, as any of which he was accused. To stop this attainder, he produced the king's pardon, under the great seal; but it was overruled by both houses, and all he could obtain by petitioning, was to have his sentence altered from hanging to beheading. He accordingly met his death with great firmness, Jan. 10, 1644—45, on a scaffold erected on Tower-hill, in the seventy-second year of his age. His warmest admirers admit his extreme rashness, and little is left which can be fairly pleaded for his severity and violence, except the probability that he acted on principles which he deemed correct. Much praise has been bestowed upon his piety, but his diary shows it to have been mingled with much puerility and superstition; his dreams being regularly recorded, as well as the hopes and fears which they excited. Speaking of his learning and morals, Hume observes, "that he was virtuous, if severity of manners alone, and abstinence from pleasure, could deserve that name. He was learned, if polemical knowledge could entitle him to that praise." Among his works are sermons; Annotations upon the Life and Death of King James; his Diary, edited by Wharton; the Second Volume of the Remains of Archbishop Laud, written by himself; *Officium Quotidianum*, or a Manual of Private Devotion; and a Summary of Devotion.

LAUDANUM. See *Opium*.

LAUDER, WILLIAM, a literary impostor, who attempted to prove Milton a plagiarist, was a native of Scotland. In 1747, he published, in the Gentleman's Magazine, an Essay on Milton's Use and Imitation of the Moderns, the object of which was to prove that Milton had made free with the works of certain Latin poets of modern date, in the composition of his *Paradise Lost*. Mr Douglas, afterwards bishop of Salisbury, in a letter, entitled Milton Vindicated from the Charge of Plagiarism, showed that the passages which had been cited by Lauder, from Massenius, Staphorstius, Taubmannus, and others, had been interpolated by Lauder himself, from Hogg's Latin translation of the *Paradise Lost*. He subsequently acknowledged his fault, and soon after quitted England for the West Indies, where he died in 1771. See Nichol's *Literary Anecdotes*.

LAUDON. See *Loudon*.

LAUENBURG, or SAXE-LAUENBURG; a Danish duchy, belonging to the German confederacy. It formerly belonged to Hanover, passed with that country, in 1803, under French government, was restored, in 1813, to its former state; in 1816, was ceded to Prussia. The Prussian government afterwards gave it up to Denmark. (See *Kiel, Peace of*.) It contains, at present, 400 square miles, with 32,000 inhabitants, is situated on the right bank of the Elbe, and is surrounded by the territories of Hamburg, Lubeck, Hanover, Mecklenburg, and Holstein. Grazing and tillage, together with the transit trade, are the sources of its wealth. It exports much wood for fuel and building. The toll on the Elbe, paid in the city of Lauenburg is said to amount to 50,000 Danish dollars annually. According to the constitution, confirmed by the king, twenty-two landholders and the three cities have each one vote in the diet. The free peasants in 111 villages are not represented. Ratzeburg, the capital, is situated on an island in a lake.

LAUMONITE; a mineral, named in honour of Gillet de Laumont. It occurs in aggregated crystalline masses, deeply striated, or in separate crystals, of several varieties of form, and sometimes in that of

its primary crystal, an oblique rhombic prism, of which the inclination of the terminal plane is from one acute angle to the other. It is white, sometimes with a tinge of red, and is translucent, and hard enough to scratch glass. By exposure to the air (even a very short time), it becomes opaque, tender, and eventually falls into a white powder; specific gravity, 2·2. Before the blow-pipe, it intumesces, and fuses with difficulty into a colourless glass. It is composed of silice 48·50, alumine 22·70, lime 12·10, and water 16·00. It was first noticed in the lead-mines of Huelgoet, lining the cavities of veins. It has since been found in trap in Ireland and Faroe, Transylvania, Nova Scotia, and in the United States, near New Haven, Connecticut.

LAUNCH. See *Boat*.

LAUNCHING. See *Ship*.

LAURA; Petrarch's mistress. It was long erroneously supposed that this lady, who has been celebrated in the sweetest strains of poetry, was only an allegorical person, or a descendant of the houses of Chabaud and Sade, who remained single, and lived at Vaucluse, where the poet had an opportunity of becoming acquainted with her. According to the investigations of the abbé Sade, *Mémoires pour la Vie de François Pétrarque* (Amsterdam, 1764—67, 3 vols., 4to); of Tiraboschi, in his *History of Italian Literature*; of Baldelli, *Del Petrarca* (Florence, 1797, 4to); of the abbé Arnayon, *Pétrarque à Vaucluse*, and *Retour de la Fontaine de Vaucluse* (Paris, 1803, and Avignon, 1805); of Guérin, *Description de la Fontaine de Vaucluse* (Avignon, 1804, 12mo); and, lastly, of Ginguené, in his *Histoire littéraire d'Italie* (2d vol.), Laura was descended from the old Provençal family of Noves, which has now been extinct 300 years, and was the daughter of the chevalier Audibert Noves, who lived in Avignon. She was born at the village of Noves, or in Avignon, in 1307 or 1308, and, after the death of her father, who left her, his oldest daughter, a large fortune, she married (1325) the young Hugh de Sade, of a distinguished family in Avignon. Laura was one of the most beautiful women of the city, which, being at that time the residence of the pope, attracted many strangers. Among them was the young Petrarch, whose ancestors had been banished from Tuscany, during the quarrels of the Guelphs and Ghibelines. It was on the 6th of April, 1327, on Monday of the passion-week, at six o'clock in the morning, that Petrarch, then twenty-three years old, first saw, as he himself says, the beautiful Laura, in the church of the nuns of St Clara; and, from that moment, he was seized with a passion as violent as it was lasting. His vain efforts to lead her from the path of duty, and his ineffectual attempts to conquer a hopeless passion, plainly show that his love was by no means Platonic. He acknowledges, however, that he never received the smallest favour from her, and bestows the highest praise on her virtue. Laura certainly felt flattered by the devotion of the young poet, and was polite and kind towards him, as long as she saw nothing in his attentions to alarm her; but treated him with severity whenever he endeavoured to express the warmth of his passion. For more than twenty years, Petrarch sang the object of his love, and endeavoured to excite a reciprocal passion, or to conquer his own. During this long period, by alternate severity and kindness, Laura succeeded in retaining him a captive to her charms, without ever suffering the least stain on her honour. She never saw the poet in her own house, because the manners of the time, as well as the jealousy of her husband, forbade it. After her marriage, she always lived at Avignon, in the house of her father-in-law, situated on the Rhone, below the papal

palace; and it was from the summit of the rock, on which the palace was built, that Petrarch delighted to gaze on her, as she walked in her garden. In the same year (1334), that Petrarch went to Vaucluse, to recover his peace of mind in this lovely solitude, Laura was attacked by an epidemic disease, which made great ravages; but she recovered, and was dearer than ever to the poet. In 1339, the painter Simon of Sienna, who had been called to Avignon to adorn the papal palace, painted Laura's picture, and gave it to the poet, who repaid him with two sonnets. Whether Laura consented to have her portrait taken for Petrarch, or whether he only obtained a copy, or whether the image of the beautiful lady was so deeply stamped on the mind of the painter, that he could afterwards paint her from recollection, cannot now be ascertained; but it is certain, that he afterwards introduced Laura into several pictures, as, for instance, those on the ceiling of the cathedral at Avignon. When Petrarch returned to Avignon, after having been crowned with laurel at the capital, Laura, whether flattered by his fame, or touched by the constancy of a lover whom long absence had rendered more dear to her, received him kindly. Petrarch saw her more frequently, and his visits to Vaucluse became less frequent and long. His poems, which were spread all over Europe, made the beauty of his mistress very celebrated, and all strangers, who came to Avignon, wished to see Laura. Charles of Luxemburg, afterwards the emperor Charles IV., saw her at a ball which was given him, and, beseeching the other ladies to make way, he approached her, and kissed her on the forehead and eyes. But the repeated fatigues of maternity, and the domestic trouble which she suffered from the ill humour of her husband, and the bad conduct of her eldest daughter, made at length such a change in her appearance, that those who saw her for the first time were disappointed. A pestilence which arose in the East, and spread desolation over Europe for three years, at length reached Avignon, in 1348, and, on the 6th April, at six o'clock in the morning, the hour when Petrarch has designated, in his mournful recollections, as that of the birth of his love, Laura fell a victim to this disease, and was buried on the same day, in the church of the convent of the Minorites. In 1551, some antiquaries obtained permission to open Laura's grave. They found a parchment enclosed in a leaden box, on which was written a sonnet, bearing Petrarch's signature. It was not, however, written in the spirit of that celebrated poet, but appeared to be the work of a friend. They also found a medal, bearing a female figure, with the inscription M. J. M. J. (perhaps, *Madonna Laura Morta Jacet*). Francis I., who visited Avignon the same year, sought out Laura's grave, wrote an epitaph on her, and ordered a monument to be erected to her; but it was never done. The box and the medal were purchased (1730), of the under sacristan, by some Englishmen; but the sonnet was lost, when the coffin, belonging to the family of Sade, was destroyed, in 1791. The tomb itself was overturned, together with the church, during the revolution. The prefect of Vaucluse (1804) caused the tomb stones, which had been given to the family of Sade, to be placed in the old cathedral of Avignon. The abbé Cuvier has endeavoured to prove, without any sufficient grounds, that Petrarch's Laura was descended from the family of Baux, and was the daughter of Ademar de Baux. (See his *La Muse de Pétrarque dans les Collines de Vaucluse*, Paris and Avignon, 1838. See the article *Petrarch*.)

LAUREL (*laurus*); a genus of plants consisting of trees or shrubs, mostly aromatic, and often remarkable for the beauty of their foliage. The leaves are

simple, generally alternate, and the flowers small and inconspicuous. It is one of the few genera belonging to the Linnæan class *enneandria*. The species inhabit the tropical parts of the globe, and the warm regions in the vicinity; two of the American species, however, extend to a high northern latitude. Cinnamon, cassia, and camphor are obtained from different species of *laurus*. The sweet bay (*L. nobilis*), so celebrated by the ancient poets, and used to decorate temples and the brows of victors, is a small ornamental evergreen tree, inhabiting the south of Europe, and north of Africa. At the present time, the leaves and berries are chiefly employed for culinary purposes. The red bay (*L. Caroliniensis*) inhabits the alluvial district of the southern parts of the United States of America from latitude 37° to the gulf of Mexico, and is found westward beyond the mouths of the Mississippi. It is a beautiful tree, growing in the low grounds, in company with the cypress, and sometimes attains the height of sixty or seventy feet, with a trunk a foot or eighteen inches in diameter. The leaves have an aroma very similar to that of the *L. nobilis*, and may be employed for the same purposes. The wood, which is strong, fine-grained, and capable of receiving a brilliant polish, was formerly employed, in cabinet-making, and afforded very beautiful furniture; but the difficulty of finding stocks of sufficient size, together with the facility of procuring mahogany, has brought it into disuse. At present it is chiefly employed in naval architecture, whenever it attains large dimensions. The wood is used also, in preference to any other, for tree-nails (wooden pins which fasten the planks of a ship to the timbers.) The sassafras, so remarkable for having its leaves either simple, or divided into two or three lobes, is also a species of *laurus*. Though usually appearing as a shrub, it not unfrequently attains considerable dimensions, growing, in a rich soil, to the height of forty or fifty feet, or even more, with a trunk of proportional diameter. It is common in America, as far north as lat. 43°, and extends westward even into Mexico. The bark of the roots, which is the most powerfully aromatic part of the plant, has been in high repute as a medicine from the discovery of America, and is still exported to Europe in considerable quantities, but its virtues have been very much overrated, although it is yet frequently employed in pharmacy. A very agreeable beverage is made, in some parts of the United States, of this bark, in combination with other substances, and it is also employed in dyeing, affording a beautiful orange colour. The *L. benzoin*, or fever-bush, is also an agreeably aromatic shrub, as widely extended throughout the United States as the preceding. Four other species of *laurus* are found in the Southern States. Michaux strenuously recommends the introduction of the camphor tree (*L. camphora*) into the Southern States, and is of opinion, that it would soon become naturalized. The alligator pear, which forms a frequent article of nutriment in the West Indies, and is much cultivated for that purpose, is also the fruit of a species of *laurus*.

LAURENS, HENRY, a distinguished American statesman of the revolution, was born at Charleston, South Carolina, in 1724. His ancestors were French Protestant refugees, who had left France about the time of the revocation of the edict of Nantes. After receiving a good education, he was placed in the counting-house of a merchant of Charleston, but was soon afterwards sent to London to fit himself for commercial pursuits, under the eye of a gentleman who had been engaged in business in Charleston. On his return, he entered into business, and, by his industry and activity, acquired an ample fortune. Having retired from business, he went, in 1771, to

Europe, in order to superintend the education of his sons, and was in London when he received the first accounts of the troubles which were beginning to agitate the colonies. With thirty-eight other Americans, he endeavoured, in 1774, by petition, to dissuade parliament from passing the Boston port bill, and exerted himself to prevent a war; but finding that nothing would be of any avail for that purpose, save dishonourable submission, he hastened home to take part with his countrymen. He arrived in Charleston in December, 1774, was chosen president of the council of safety, and soon manifested that he had lost none of his energy and habits of business. In 1776, he was elected a delegate to congress; soon after taking his seat, was made president of that body, and continued such until the close of the year 1778. He then resigned, and, in 1779, received the appointment of minister plenipotentiary from the United States to Holland. On his way thither, he was captured by the British, carried to London, and committed to the Tower. For the first month of his confinement, he was permitted to walk out with an armed guard; but this indulgence was subsequently taken from him for a time, in consequence of lord George Gordon, then a prisoner also, having met and asked him to walk with him, which, although Mr Laurens refused to do, and immediately returned to his room, was interpreted into a transgression of orders. His confinement lasted for more than fourteen months, during which, various efforts were made by the British government, to shake his constancy, but without effect. Soon after his release, he received a commission from congress to be one of their ministers for negotiating a peace with Great Britain, and, having repaired to Paris, he signed, November 30, 1782, with doctor Franklin and John Jay, the preliminaries of the treaty. On his return home, he was received with every mark of esteem, but declined all offices. His health had been broken by his imprisonment, and, after passing the last years of his life in agricultural pursuits, he died December 8, 1792, nearly seventy years of age. According to an injunction contained in his will, his body was burned, and his bones collected and buried.

LAURENS, JOHN, lieutenant-colonel, son of the foregoing, after receiving a liberal education in England, returned to his country, and joined the American army in 1777. The following summary account of his military career is taken from Garden's interesting Anecdotes of the American revolution. "His first essay in arms was at Brandywine. At the battle of Germantown, he exhibited prodigies of valour, in attempting to expel the enemy from Chew's house, and was severely wounded. He was engaged at Monmouth, and greatly increased his reputation at Rhode Island. At Coosahatchie, defending the pass with a handful of men, against the whole force of Prevost he was again wounded, and was probably indebted for his life to the gallantry of captain Wigg, who gave him his horse to carry him from the field, when incapable of moving, his own having been shot under him. He headed the light infantry, and was among the first to mount the British lines at Savannah; displayed the greatest activity and courage during the siege of Charleston; entered, with the forlorn hope, the British redoubt carried by storm at Yorktown, and received with his own hand the sword of the commander; by indefatigable activity thwarted every effort of the British garrison in Charleston, confining them, for upwards of twelve months, to the narrow limits of the city and neck, except when, under the protection of their shipping, they indulged in distant predatory expeditions; and, unhappily, at the very close of the war, too carelessly exposing himself in a trifling skirmish near Comba-

bee, sealed his devotion to his country in death." It is related by judge Johnson, in his life of general Greene, that the greater part of the night, in which the fatal skirmish took place, was spent by Laurens in a jocund company of ladies; that the expected rencounter was the subject of the gayest badinage; and that the company did not separate until two hours before the time when the colonel was in motion with his detachment. The sorrow at the news of his death was deep and universal. Washington, into whose family and affection he had won admission, mourned him as a lost son. Such a combination as was found in him of chivalrous gallantry, patriotism, ardour, elevation, and rectitude of soul, with unaffected modesty, information, frankness, vivacity, and polish of manners, has rarely been seen. He was the delight of every social circle, and the admiration of his companions in arms. There is one act of his life, which, perhaps, more than any other, entitles him to the gratitude of his country. In the autumn of 1780, he was sent, as a special minister, to France, in order to negotiate a loan from the French government, and, on his arrival in Paris, immediately entered upon the business of his mission; but, after a delay of more than two months, on the part of the government, to return a definitive answer to his application, he determined, contrary to all the rules of etiquette, to present a memorial himself to the king, at the levee. He first made the minister, count de Vergennes, as well as doctor Franklin, the American envoy, aware of his intention, and, notwithstanding the urgent entreaties of the latter, carried it into effect. The king, however, received the memorial graciously, and matters were soon arranged in a satisfactory manner. The consequences of his successful boldness in this affair were all-important for the American cause, which would have been, perhaps, irretrievably ruined by any further procrastination. An account of the transaction, from the pen of the secretary of the mission, is to be found in the *American Quarterly Review*, vol. i. p. 425.

LAURISTON, JAMES ALEXANDER BERNARD LAW, count de, grandson of the celebrated projector Law, was born in 1768. He embraced the military profession at an early age, and served in the artillery, in which he obtained a rapid promotion, owing to his own activity, and to the friendship of general Bonaparte, whose aid-de-camp he was, and who employed him on several important missions. He commanded, in 1800, in quality of brigadier-general, the fourth regiment of flying artillery, at La Fère. In 1801, he was chosen to convey to England the ratification of the preliminaries of peace, and was received with enthusiasm by the people of London, who took the horses from his carriage, and conducted him in triumph, to Downing street. He served in every campaign of importance in Spain, Germany, and Russia. In 1809, he penetrated into Hungary, and took the fortress of Raab, after a bombardment of eight days. July 6, he decided the victory in favour of the French at the battle of Wagram, by coming up to the charge, at full trot, with 100 pieces of artillery. In 1811, he was appointed ambassador to St Petersburg. The object of his mission was to obtain the occupation of the ports of Riga and Revel, and to exclude British ships from the Baltic. This mission having failed, M. de Lauriston was employed in the Russian campaign, and, after the taking of Moscow, was sent with proposals for an armistice to the emperor Alexander, which were rejected. After the disastrous retreat from Moscow, he commanded the army of observation on the banks of the Elbe, and, during three months, defended that river with a small force, preventing the enemy from penetrating into Hanover. He fought with great valour at the battle of Leipsic,

but, being taken prisoner, was conducted to Berlin, where he was treated with favour and distinction. After the conclusion of the general peace, Louis XVIII. created him a knight of St Louis, grand cordon of the legion of honour, and captain-lieutenant of the Gray Musketeers. After March 20, 1815, he followed the king's household to the frontiers of France, and then retired to his estate of Ruchecourt, near La Fère, without mingling in any of the transactions of the hundred days. On the return of Louis, he was nominated president of the electoral college of the department of L'Aisne, lieutenant-general of the first division of royal foot-guards, and member of the commission appointed to examine into the conduct of such officers as had served from March 20 to July 8, 1815. He was created a commander of St Louis in 1816, and presided, in the course of the same year, at the trial of admiral Lincol, count Delebarde, &c. In 1823, he was appointed marshal, and commanded the second *corps de réserve* of the army in Spain. He died in 1828.

LAUSANNE, capital of the Pays-de-Vaud, a Swiss canton, has 1300 houses, with 10,000 inhabitants; lon. 6° 45' 30" E.; lat. 46° 31' 45" N. It is most beautifully situated about a mile from the lake of Geneva. Lausanne lies high, with the lake and snowy Piedmontese Alps in front, whilst the shore of the lake is covered with vineyards. Since 1526, there has been an academy at Lausanne, which, in 1803, was elevated to an academical institute, with fourteen professors and a rector. It has works in gold and silver, printing-offices, and some trade in wine; but its chief profits are derived from the numerous foreigners who resort to it from all countries on account of its charming situation, or to perfect themselves in French. Lausanne has a *société d'émulation*, societies for natural history and agriculture, and a Bible society. Formerly the city belonged to Berne, whose bailiff lived in the episcopal palace. The bishop transferred his residence to Freiburg, when Lausanne embraced the Calvinistic religion. Haller, Vahnen, and Gibbon resided here for a considerable period.

LVALETTE; the name of several individuals distinguished in French history, of whom we shall mention only two, the subject of this article and that of the following.—Jean Parisot de Lavalade, the forty-eighth grand master of the knights of Malta, was born in 1494, of an ancient family. Lvalette, unanimously elected grand master in 1557, showed himself equally active and wise as head of his order and as a general. His ambassadors were admitted at the council of Trent among those of the most powerful monarchs. He restored the internal organization of his order, he distinguished himself particularly by the brave defence of Malta against Soliman II., who attacked it with a force of 80,000 men, and whom he forced, after a siege of several months, to retire in 1565, with a loss of more than 80,000 men. He then took the fortress La Valetta in Malta, refused the cardinal's hat, and died in 1568. See *Malta*.

LVALETTE, MARIE CHAMANS, count de, was born at Earis, in 1769, of obscure parents. His mother was a nurse, often employed by the famous accoucheur Baudelocque, who, perceiving the promising talents of the youth, furnished her with the means of giving him an education far superior to his birth. Young Lvalette was destined for the clerical profession, and wore the habit of an abbot for some time, but afterwards took to the study of the law. The revolution, in 1789, gave another direction to his ambition. He became an officer in the national guards, and in August, 1792, defended the Tuilleries

He afterwards served in the army of the Rhine and that of Italy, with such distinction, that he rose rapidly. Bonaparte made him his aid-de-camp, intrusted him with his secret correspondence, and gave him in marriage Mlle. Beauharnais, the niece of Joséphine. He accompanied Bonaparte to Egypt, and, soon after the establishment of the consular government, was made count, and a commander of the legion of honour. In 1814, he was removed from the post-office; but when Louis quitted Paris, in 1815, he repaired to the office, in company with general Sebastiani, and summoned his successor, M. Ferrand, to surrender his place, only allowing him a few minutes to collect his papers, but, at the same time, treating him with great politeness. He then took measures to accelerate the progress of Napoleon, and conducted himself with extraordinary vigilance and activity. For these services he was created a peer of France (June 2), and continued in his office till the return of the king. In the month of November following, he was brought to trial, and condemned to death as an accomplice of Napoleon. His appeal and application for pardon having failed, preparations for his execution on Thursday, December 21, were making, when his wife, having obtained permission to visit him, came, on the 20th, in a sedan chair, and dined with him, attended by her daughter and the governess. About seven in the evening, the two latter appeared at the keeper's lodge, apparently supporting Madame Lavalette, who was closely muffled up, held a handkerchief before her eyes, and exhibited every symptom of the profoundest distress. After a few minutes, the keeper of the prison repaired to Lavalette's apartment, where he found Madame Lavalette in his place. He set his turnkeys and keepers in motion, but, in spite of their activity, nothing was found but the sedan chair, in which the young daughter had taken the place of her father, who had suddenly disappeared at the *Quai des Orfèvres*. The jailer was then removed and confined, the barriers were closed, and expresses were sent in every direction, with the description of Lavalette's person, who contrived to lie closely concealed for a fortnight, in spite of the vigilance of the police, during which time he meditated on the most effectual method of completing his escape. He had recourse, for that purpose, to three Englishmen—Messrs Bruce, Hutchinson, and Sir Robert Wilson, who were already known for their zeal in support of the principles of liberty, and for their hostility to the tyranny exercised by the Bourbons. By means of these gentlemen, he procured the uniform of a general officer in the British service, and repaired, January 7, at half-past nine at night, to the apartments of captain Hutchinson. The next morning, at seven o'clock, he got into a cabriolet with Sir Robert Wilson, passed the barriers without being recognised, and arrived the following day at Mons, where his guide took leave of him. He then took the road to Munich, where he found an asylum among powerful friends and connexions. Irritated by his escape, the government had the cruelty to retain his wife for some time in prison, because she had been necessary to the escape of her husband—a treatment which disordered her senses, and she has since been a confirmed lunatic. Lavalette was pardoned, and returned to France in 1821.

LAVATER, JOHN GASPARD, was born in 1741, at Zurich, in Switzerland, where his father enjoyed the reputation of a skilful physician and good citizen. The severity of his mother somewhat depressed the mind of the boy, who was endowed with a lively imagination, and he early gave himself up to solitary reveries. While yet at school, he was

persuaded that he had received direct answers to his prayers. His imagination, even at that early period, appears to have been so actively employed, that he never acquired much knowledge of philosophy or classical antiquity. In 1763, he travelled, in company with Fuseli—afterwards a distinguished painter in London—to Leipsic and Berlin, and became acquainted with the scholars and theologians of Northern Germany. In 1764, he returned to his native city, and, in 1767, appeared as a poet in his *Schweizerlieder*, which, as well as his *Aussichten in die Ewigkeit* (1768), gained him many admirers. In 1769, he was appointed one of the ministers at the orphan church at Zurich. His sermons were rendered attractive by their pleasing style, his enthusiastic zeal, and a certain mysticism which always characterised him. They were printed in 1772, and were admired even in foreign countries. All his activity was, in fact, devoted to the service of religion, until he undertook his work on physiognomy. Lavater had become acquainted with a great number of persons, and his lively imagination had led him to the conclusion that there exists a much greater connexion between the internal man and the external expression in the face than is generally supposed. He reduced this external expression of disposition and character to a system, and considered the lines of the countenance as sure indications of the temper. He had adopted this idea in 1769, and collected the features of distinguished people from all parts of the world. His great work (in four volumes 4to), under the modest title *Physiognomical Fragments* (1775 et seq.), made him known all over Europe. It was rendered valuable by the many portraits it contained, mostly well executed by some of the engravers of Germany. Lavater had added explanations, in a poetical style, full of enthusiastic exclamations. As may easily be imagined, a theory so novel found warm admirers, whose zeal often rendered it ridiculous, and Lichtenberg satirized it in his *Essay on Cues and Tails*—one of his most successful compositions. Lichtenberg's exclamations on the contour of a pig's tail, or a happily-adjusted cue, equal the raptures of Lavater viewing the physiognomy of an Alexander. According to Las Cases, Napoleon declared himself convinced, by long experience, that no reliance was to be placed on the expression of the face—an opinion which is perhaps true to a greater extent in respect to talents than disposition. Lavater himself seems to have given up his theory in a great degree. (See *Physiognomy*.) He published several other works, including poems and works of religious instruction, and his reputation became so great, that his journeys resembled triumphs. He refused better appointments in foreign countries, and became minister at St. Peter's church in Zurich. During the revolution, he spoke with boldness against the new order of things, the Swiss directory, &c., and was finally transported to Bale, in the year 1796. He was again set at liberty; but, on the capture of Zurich (in September 26, 1799), by Massena, while occupied in the street, assisting the distressed, and giving refreshment to exhausted soldiers, he received a shot in his side.\* He lingered above a year, during which he wrote several works, and died January 2, 1801. Lavater was one of the most virtuous of men, so that a

\* According to Raoul-Rochette's *Histoire de la Révolution Helvétique* (Paris, 1822), neither a Russian nor a Frenchman was his murderer: "Le crime appartient tout entier à la fureur des partis; et Lavater qui connaissait son assassin, emporta dans la tombe cet horrible secret avec tous les autres secrets de sa belle âme et de son inépuisable charité."

biographer says of him, "Had he lived in early times, he would now be adored as a saint, because every thing which the church requires from a saint he had in perfection—charity, love of mankind, and unrelaxing zeal in the cause of Christ." He did much for practical theology. Lavater owed little to learning, but drew chiefly from himself. His work on Physiognomy has been several times translated into English. Of the English translations, we may mention Hunter's (Lond., 1789, 5 volumes 4to.) A valuable French edition appeared in 1809 (Paris, 10 vols.)

**LAVENDER**; a delightfully fragrant plant, is a native of the south of Europe. All the labiate plants are aromatic and stimulating, but these properties are more exalted in this plant than in any other of the tribe, especially when it grows in a warm and sunny exposure. Indeed, in such situations, it sometimes contains one fourth of its weight of camphor. To the abundance of this plant is attributed the superiority of the honey in certain parts of Europe. The volatile oil, distilled water, and tincture of lavender, are much employed in official preparations, and as perfumes. The flowers yield by far the greatest proportion of oil.

**LAVINIA**; a daughter of king Latinus and Amata. She was betrothed to her relation, king Turnus, but, because the oracle ordered her father to marry her to a foreign prince, she was given to Æneas, after the death of Turnus. (See *Latinus*.) At her husband's death, she was left pregnant, and, being fearful of the tyranny of Ascanius, her son-in-law, she fled into the woods, where she brought forth a son, called *Æneas Sylvius*.

**LAVINIUM**, or **LAVINUM**; a town of Italy, said to have been built by Æneas, and called in honour of Lavinia, the founder's wife. It was the capital of Latium, during the reign of Æneas.

**LAVOISIER**, ANTHONY LAWRENCE, a celebrated French chemist, whose name is connected with the antiphlogistic theory of chemistry, to the reception of which he contributed by his writings and discoveries. He was born at Paris, Aug. 16, 1743, and was the son of opulent parents, who gave him a good education. He acquired an intimate knowledge of the physical sciences, and first distinguished himself by a prize memoir on the best method of lighting the streets. Two years after, in 1768, he was chosen a member of the academy. About this time, he published several tracts, in periodical works, on the analysis of gypsum, the crystallization of salt, the congelation of water, on thunder, the aurora borealis, &c. Journeys to different parts of France furnished him materials for a mineralogical chart of the kingdom, intended as the basis of a work on the revolutions of the globe, and the formation of the strata of the earth, outlines of which appeared in the memoirs of the academy for 1772, and 1787. The discoveries of Black, Cavendish, Macbride, and Priestley, relative to the nature of elastic fluids or gases, attracted the notice of Lavoisier, who entered on the same field of inquiry, with all his characteristic ardour in the cause of science; and, possessing the advantage of a considerable fortune, he conducted his experiments on a large scale, and obtained highly interesting results. In 1774 appeared his *Opuscules chimiques*, comprising a general view of what was then known relative to gaseous bodies, with several new experiments, remarkable for their ingenuity and accuracy. Doctor Priestley's discovery of what he called *dephlogisticated air*, afterwards generally termed *oxygen gas*, furnished Lavoisier with a fresh subject of research; and, in 1778, he published an essay on this substance, and its influence in the production of acids, developing the principle of a new chemical theory. This was further illustrated by his

experiments on the composition of water, by burning together the oxygen and hydrogen gases, and by its analysis affording the same principles; and the system was completed by his theories of combustion and oxidation (see *Oxygen*), the decomposition of atmospheric air, his doctrine of caloric and its influence in causing the solid, liquid, and gaseous states of bodies; and the whole theory was laid before the public in his *Elements of Chemistry*, which appeared in 1789, and was speedily translated into English and other languages. (See *Chemistry*, and *Chemical Nomenclature*.) M. Lavoisier rendered many services to the arts and sciences, both in a public and private capacity. When the new system of weights and measures were brought forward, he contributed to its improvement by some novel experiments on the expansion of metals. He was consulted by the national convention as to the best method of manufacturing assignats, and securing them from being forged. In 1791, the committee of the constituent assembly applied to him for information preparatory to the adoption of an improved system of taxation, a consequence of which he drew up a work, which was published under the title of *Richesses territoriales de la France*, relating to the production and consumption of the country. About this time, he was appointed one of the commissioners of the national treasury—an office which afforded him an opportunity of exercising his spirit of systematic arrangement. His house became a vast laboratory; the most skilful artists were employed to construct the necessary instruments and apparatus for his philosophical researches. He had *conversations* at his house twice a week, at which were discussed the theories, opinions, and discoveries of learned contemporaries. With other farmers-general, he was condemned to death by the revolutionary tribunal of Paris, on the charge of being a conspirator, and of having adulterated the tobacco with ingredients obnoxious to the health of the citizens, and, on this frivolous pretext, was beheaded by the guillotine, May 8, 1794. When he found his fate inevitable, he petitioned for a few days respite, in order to make some interesting and important experiments which he had in view; but the favour was denied him. M. Lavoisier married, in 1771, the daughter of a farmer-general, a lady of agreeable manners and considerable talents, who not only participated in her husband's philosophical researches, but also cultivated the arts with great success, and engraved with her own hand the plates for one of his publications. She subsequently became the wife of count Rumford.

**LAVORA**, or **TERRA DI LAVORO**; a principality of Naples, bounded north by Abruzzo Ultra, and Abruzzo Citra, east by Molise, and Principato Ultra, south by Principato Ultra, and the gulf of Naples, and west by the Mediterranean and the Campagna di Roma; about 140 miles in length, and thirty-three wide where broadest. It is populous and fertile, yielding abundance of corn, wine, oil, and other productions of Italy. Anciently it was called *Campania*; in the middle ages, the *Castellum of Capua*. Caserta is the capital; Gaeta the principal port. Population, 625,600; square miles, 1696.

**LAW, LEGISLATION, CODES.**—1. *Law* is the very soul of a people; not merely those which are contained in the letter of their ordinances and statute books, but still more those which have grown up of themselves from their manners, and religion, and history. Several modern continental jurists, as John G. Schlosser, and Hugo, have shown how little, in legislation, caprice can prevail over the silent but irresistible influence of public opinion. And even the authors of the Code Napoléon have said, with no less elegance than truth, that no legislator can escape

that invisible power, that silent judgment of the people, which tends to correct the mistakes of arbitrary legislation, and to defend the people from the law, and the lawgiver from himself. Frequent experiments have shown that laws, at variance with the manners and religious views of a people, cannot be forced upon them, however well meant, and however beneficial may have been their influence upon other nations; and that, by means of laws, a legislator, can no more elevate his countrymen to a higher degree of refinement, without passing through the intervening steps, than he can reduce them again to a condition above which they have risen in the natural course of events. Hence Frederic II. of Prussia was more happy in his reforms than Joseph II. For it was by no means the intention of the Prussian legislator to give his subjects a new system of law, but rather to sanction that which they already possessed; to adapt the letter of the ancient laws to the notions of right which had gained a footing in the spirit of the nation, and, above all, to remove all those uncertainties which had necessarily sprung from the use of a foreign code, which had checked improvement in practice. Indeed, it is not the duty of a skillful legislator to create new laws; but only to develop those which existed prior to any express recognition, and to introduce, with prudence, those positive rules which cannot be deduced from general principles, as the determination of the length of minority, the period of superannuation, the amount of punishments, &c.; in which the principles of natural right are reduced to a practical application. To the province of the practical legislator belong also those forms which are required in the application of legal principles; as the formalities of contracts and of judicial processes, and the rules of evidence, in all which it should be kept in mind that these positive institutions do not, of themselves, constitute law, but are the mere mechanism to facilitate the use of it. They should be viewed only as the means of promoting a higher end. The view of the original ground of laws is a point on which not only the schools of European jurists differ, but on which the most important principles of public law come into collision.

2. The schools of modern jurisconsults may be reduced, in reference to their principal characteristics, to four, although these are variously modified, and, in many respects, run into one another. In the last century, with few exceptions, the *practical* school predominated, which, on the one hand, esteemed the authority of courts and individual jurists higher than the law, and, on the other, was influenced, in an important degree, by philosophy, particularly that of Leibnitz and Wolf. Arguments were, for the most part, drawn with great logical precision, from the nature of the case. The members of this school felt themselves justified in departing from the letter of the written law, either whenever it seemed not adapted to the existing case, or reference could be made to the decisions of courts on the same point. By this school were introduced a multitude of new opinions, supposed equities, and milder punishments; and their fundamental views were not altogether erroneous. They proceeded on the true notion, that the laws of a people are the result of its own peculiar character, and must take their hue from this. They tried to help the letter of the old laws, by deductions from the nature of things, and, by adhering to precedents, to attain to that harmony in the administration of justice, which alone can secure the public confidence. The influence exerted by this school on the legislation of the eighteenth century was very great, particularly through Nettelbladt and Daries; and the code of Prussia, in particular, may be considered as

its work. But it wanted a proper system of judicial tribunals, to prevent that fluctuation in practice, in consequence of which all certainty, in regard to law, was lost, so that the result of the decision of the simplest cause could hardly be conjectured beforehand. The practical school was divided again into two parties, which agreed only in this, that the jurisconsults, or the judges, might look beyond positive law; but were opposed to each other in so far that one party recognised nothing but the authority of some favourite casuist, and the usage of courts; the other regarded natural right, and what they called *reasonableness*, as the basis of all their decisions. The former almost always carried the day; for it often happened that the latter opposed them only till they had become familiar with the routine of practice, and felt themselves at home in it. In the last ten years of the eighteenth century, new views suggested themselves to the *philosophical* jurists. A more perfect and living philosophy had examined afresh the foundations of science. Many a fabric was shattered, which had preserved the appearance of soundness only in consequence of negligence. At the same time, society took a new turn, and every thing seemed aiming at an ideal perfection. All former obstructions in the way of legal reform appeared to be set aside. France became a republican state, and the doctrines of natural right were introduced into practice. But things have changed again, so that philosophical law has made but little advance, and has gained but little influence in courts of justice. Philosophical treatises, however, have appeared on some departments; as on criminal law, on civil process, and particularly on public and ecclesiastical law. But such works can have no real value without a profound and accurate treatment of positive law, and have, therefore, produced but little effect. The difference of opinion, in the two parties above-mentioned, has been of practical importance only on one occasion, viz. when it was proposed to prepare new bodies of law for Germany, or to take from the French legislation (which deserves so much respect in regard to public law), the rules of civil and penal law, and the forms of procedure. This plan presupposed that a code might be formed on purely philosophical principles, which, being adapted to mankind in general, would suit all nations and all times, and become the basis and essence of every other. Corrections might be made in this ground-work by degrees, as the development of the science of law pointed out deviations from the requisitions of natural justice; and the peculiarities of the legislation of each people might be added. For even those who believed that all positive legislation was based on a foundation so unalterable and eternal, could not help seeing that the additions to be made, for the purposes of practical application, must be drawn from empirical premises, which were neither suited to all people, nor constant to any given people; so that such a code, drawn from natural law, must still leave a wide field for positive legislation. This view was taken, particularly in considering the value of the French codes, the adoption of which, in Germany, had been recommended. It was inquired whether the civil code of Napoleon had solved the great problem how to establish a code based on natural justice, and capable of so universal application as to be equally adapted to people living on the Vistula and the Seine, on the Elbe, and Po, and Tiber. It was soon perceived that the Code Napoleon did not reach this ideal. On this occasion, the contest between the philosophical and historical jurisprudence came up, which was afterwards particularly revived by Savigny's *Vom Beruf unserer Zeit zur Gesetzgebung*, 1815, (the Call for Codification in our Times.) The

peculiar characteristic of this third school of modern jurists—the *historical*—is, that they regard no legal principles as capable of universal and unconditional application. They view law as a mere result of the accidental relations of a people, and as changing with them. According to the principles of this school, every thing may be right, even slavery, and many other things which the philosophical school declares to be a violation of the universal rights of man, and absolutely wrong. The historical school allows a very narrow sphere to that legislation in which law is based on the will of the lawgiver, and a very large one, on the contrary, to the customary law, which commences and perpetuates itself by popular usages, and the decisions of courts. Its ideal is the Roman law, as it is presented in the writings of jurists before Justinian. Every innovation in the law, on the part of government, it regards as dangerous; and especially new codes, which interrupt the silent growth of legal rules in a country. So far, this school agrees with the views of the practical school above-mentioned, from which in fact, it originated. But it rejects all reasons deduced from a supposed nature of things (or, indeed, from philosophical opinions of right), and derives existing law, not from the decisions of courts and colleges, in which it perceives many glaring errors, but from ancient laws and law-books. It regards as truly right, not what modern times have recognised and followed as right, but what they would have esteemed right, if they had properly understood the ancient sources; and therefore considers that all improvement must be the result of a thorough examination of history. Notwithstanding the manifest inconsistency of this reasoning,—since, if the system of law, in any country, is formed by self-development, the newest shape is always the only one that ought to be recognised, and the present cannot be explained from the past,—this view has met with much acceptance, since it avers that whatever is, is right, from the very fact that it is; and in history, by which almost any principle may be proved or refuted at pleasure, it finds a means of crushing every desire of reform; but it is most favoured because it declares all efforts for something higher to be both foolish and wrong. This view, however, has, doubtless, already reached its acme. It has the merit of having directed to the only successful way of understanding laws by the aid of history; but the erroneous expectation cannot long be maintained, of discovering what should be, from knowing what is, and how that which is, grew up. For, although we may be set in the right way by history, yet nothing but philosophy can direct us to the proper end. History and philosophy supply each other's defects, and either of them, by itself, leads to partial views. It is only together that they can teach us the true science of law, and impart the wisdom requisite for legislation. A fourth view has been advanced, in modern times, which may be termed the *strict judicial* (*legistic*). Justly offended at the authority over the laws assumed by the practical school, and the uncertainty which had resulted from the fluctuations of their practice, impatient of the toilsome researches of an historical jurisprudence, and convinced that the philosophical school could afford materials to the legislator only, and not to the judge, a respectable number of jurists abandoned the authority of existing practice, and returned to the positive laws, though less to the spirit of them than the latter, and frequently to the letter of those laws of which the existence was scarcely known among the people. Much has been said of the injury which attends a sudden change of the laws, by introducing a new code. But, if the object of such a code is to confirm and sanction the ideas of right already prevalent among a people, it can never bring with it con-

sequences so pernicious as followed the calling up from oblivion, and adopting into use, of antiquated laws, Roman forms and subtleties, and the *crus* penal laws of the sixteenth century. In case of the literal application of these old laws, no regard can be paid to the circumstances of the age or to the peculiar character of the particular ordinances; and, in consequence of the incompleteness and want of technical accuracy in the ancient legislation, the laws of the empire, the old and new ordinances of particular countries, papal ordinances, Roman constitutions, and fragments of legal writers, are unavoidably mixed up in the most embarrassing confusion, to form a mosaic, which has the outward appearance of an organised whole, but is wholly destitute of inward, living energy. The historical school is right in maintaining that laws can be properly comprehended only by an historical examination of their development; but it has fallen into the error of the *legistic* school, in asserting that the deficiencies which are found in every positive institution should be supplied, not from the fountain of all right, but either by the aid of historical hypotheses, which attribute the most artificial systems of nations in the early periods of civilisation, or by heterogeneous additions from wholly different systems of legislation. In so doing, the historical school has particularly forgotten that the objects of their veneration, the juridical classics of Rome, owed their greatness to a perpetual habit of reverting to the maxims of natural law (their *equitas*). Even the Roman lawyers recognised an universal right, which exists prior to all positive legislation, and without it, and, at the same time, in and with it,—the rule of conduct wherever the precepts of positive law have not yet reached. There is an important difference between a maxim of law created by a positive ordinance, and one only acknowledged by it as already existing in natural equity. In the first case, the law cannot extend beyond the immediate object of its creation; in the second, it is of universal application. Of special importance is this distinction in deciding concerning relations and acts without the bounds of a state,—for example, a crime committed abroad,—cases in which positive law has a very limited application. But, however narrow the last-mentioned *legistic* view may be, it has effected much good, by bringing to light the imperfection, and, in some sense, the utter worthlessness, of the existing positive law, and thus aided to promote the reform, which in several German states, is so necessary.

3. If the question should arise, From what public organ the improvement of laws should proceed, it may be answered, The various juridical theories exhibit a great practical difference. But, at least, the two principal parties—the historical and philosophical—are perfectly agreed in the opinion, that mere caprice, which sees in laws only a means of promoting its own favourite ends, should be, as far as possible, excluded; and it is also agreed, that legislation is an office with which neither the judiciary nor the executive departments can be concerned without injury to each of them. Nothing can defend men from the arbitrary exercise of power but a separation of the executive, legislative and judicial authorities; for in no other way can each of these three powers be kept within its natural limits. The great discrepancy, both in the intrinsic nature of these powers, and in the character of their results, makes it important that each of them should be administered by a separate organ. To govern is the business of the state. The executive government is the organ of the people's will. The characteristic of its acts is command. Such commands, however, are not irrevocable, for at any moment, they may be repealed. Opinions contrary to them may

advanced; and, if they encroach on previous rights, the aid of courts may be enlisted in opposition to them. Law, on the contrary,—and, on this point, the philosophical and historical jurisprudence agree,—is founded, not upon any will, but on the discovery of a right already existing, which is to be drawn either from the internal legislation of human reason, or the historical development of the nation. The law, too, is not irrevocable, nor can any sanction make it so; but as long as it exists, it is of irresistible and universal force. Finally, the judicial decision is binding only on those who have occasioned its application by resorting to judicial proceedings; but, for such, it is an unchangeable rule, and no power whatever can subvert it. The different character of these public functions must not only be obvious in their external forms, so as to be understood by every one who would know his duty, but the very nature of the provisions which they require for their operation is so different as to furnish sufficient ground for making the executive, legislative and judicial departments distinct in their organisation. But it is a great error of modern (constitutional) politics, that they have conceived of this division of duties, as if all connexion and mutual influence of the three powers must be done away; hence the election of judges by the people, and a legislation which could be neither urged nor restrained by the executive (no veto, or only a limited one). This very naturally produced political dissensions, which could only end in the ruin of the state. But, if the executive power is what it ought to be, nothing can be done in the commonwealth without its orders; and both the legislative and judiciary departments must receive from it the impulse of their activity. The convocation of the legislative body, and the proposal of laws, belong to it; and without its consent, no law can become obligatory upon the people. The execution and promulgation of the laws necessarily rest with the executive, and are necessarily joined with an unlimited veto. On the other hand, the influence of the executive government on the legislative should be merely a negative influence, and on the administration of justice, a formal one; i. e. no law should be passed without its consent, and the judges should receive their offices from the executive, while the executive is to see that they do their duty; but how they shall speak cannot be prescribed to them. (See *Courts*.) This is the only means by which unity and harmony, in the action of the public authorities, can be maintained, while every branch of power is supported by the other, and kept in the right path. The entire separation of these three powers is an error which, wherever it has existed, in ancient or modern times, has brought upon the people as great sufferings, as if they had been subject to an arbitrary and unlimited dominion.

4. The historico-philosophical view of the sources of laws leads us to results concerning the organisation of the legislative authorities, which, it is to be regretted, have been often too much overlooked. The consequence of the unreasonable notion, that legislation is an act of the will, was an idea that the general will of the people might be ascertained, if all the different interests to be found in the people could be brought together; or, as this is, in fact, impossible, it was considered sufficient to unite, in representative assemblies, the most important interests—those of agriculture, commerce, and manufactures. In respect to the administration of government, and the judicious choice of means to promote the high ends of the state, this sort of representation may be found sufficient. But, when the question is respecting the establishment of laws, in the highest sense of the word, the most comprehensive intelligence is re-

quired. A popular representation, for this purpose, should not represent the fluctuating, capricious will of the people, influenced, as it is, by interest, prejudice, and passion. On the contrary, it should be a mirror to reflect all the intellectual power of the nation. Consequently the representatives should be chosen from the most learned, and enlightened, and experienced men, who have the best opportunity to become acquainted with the wants of the people and the defects of the existing laws. That it cannot be concluded that a man possesses these qualifications, because he owns a piece of ground, is very clear. And it is equally manifest, that it is a great mistake to esteem such a possession a security for good intentions. Disinterestedness is no consequence of wealth, but of the habit of self-denial; and he learns it much more perfectly who has been inured to it from his youth, than one who has, perhaps, never known a want. To regard landed proprietors as the proper citizens, and others as mere tolerated tenants of the state, is an absurdity. Landed property is the offspring of the state, and not *vice versa*; and the state cannot so distribute the soil, that it may depend on the will of the owner to deprive others of the means of subsistence. The more a natural, distinct interest separates landed proprietors, and, indeed, in some sense, the cultivators of the soil also, from the rest of the community, the more should it be made a main object of public institutions to prevent one party from gaining a decided and permanent superiority. But political institutions now have frequently the opposite tendency—a circumstance which, in some places, has had a remarkable influence on taxation. The second consequence, resulting from the view of legislation here proposed, is, that the number of representatives needs not be proportionate to the number of the people. In a large state, a larger number of deputies is not needed to represent the intellectual capacity of the people; and a small state, if it regards the ends of legislation, properly needs as many persons in its representative assembly as the larger. For it should comprehend so many different kinds of knowledge and talent, that no subject may arise on which a judicious decision cannot be made by the body, by the aid of persons within itself; and that the laws may all have the stamp of moderation, arising from due attention to all interests, which often leads, though by no means necessarily, to half measures. This is the greatest difficulty for smaller states, and they can only prevent it by accommodating their legislation to that of their neighbours. The management of the public affairs of communities, from the village up to the state, cannot be called legislation, in the sense in which we are now considering the subject: these may be suitably administered by even the smallest state. But if a small state undertakes to establish a peculiar system of civil rights, of legal procedure, of penal laws, &c., it will receive less advantage from such an insulated system than of injury, from the bars to intercourse with its neighbours, which must result from such institutions. Hence it is altogether desirable that, in states which are only minor divisions of one nation, having the same religion, manners, and cultivation, the municipal laws, and the institutions for their administration, should as far as possible, be made common to the whole, although matters of political administration might be kept distinct. Thus they might secure to themselves the advantages enjoyed by larger states, in the preparation of like laws by experienced colleges (as the French council), or by juridical commissions, so as to be accommodated to all the existing institutions. Representative assemblies would be freed from the embarrassment of deliberating and deciding upon topics, of which perhaps few, per-

haps not a man among them, has any knowledge. But this is not to be observed in small states only: very large ones sometimes suffer still more from this evil; for though, on one side, the mass of knowledge united in the body is greater, on the other, a greater number of ignorant men embarrass and confuse: and while too many take part in making laws, but few take an interest in the subject. The thoughtlessness with which this important duty has been performed in England till the present time, is shown by Miller, in an Inquiry into the Present State of the Statute and Criminal Law of England (London, 1822). The people of England, therefore (the paradise of the customary law), are at length beginning to feel the urgent need there is of reducing the chaos of single enactments into general codes. This is called the *consolidation of laws*. Several learned individuals have undertaken to make such compends.

We now propose to offer some observations, explanatory of the views of lawyers accustomed to the jurisprudence of the common law, on this interesting subject. Civilians are (it seems from the preceding part of this article) divided into several schools, professing different opinions, and actuated by different principles. The course of the common law naturally leads those who are engaged in its studies, to take practical rather than theoretical views of almost every department of it. Hence they can hardly be said to be divided into different schools, or to indulge much in what may be called *philosophical, historical, or antiquarian* inquiries. The actual system, as it exists, is that which they principally seek to administer; and it is only occasionally that very gifted or bold minds strike out into new paths, or propose fundamental reforms. In the present age, however, a spirit of inquiry is abroad, and the value and extent of codification have, among other topics, been matter of warm controversy among practical lawyers, as well as among practical statesmen. We shall speak of this subject in the sequel. Legislation, in its broadest sense, includes those exercises of sovereign power, which permanently regulate the general concerns of society. Its chief object is to establish laws. And by a *law*, we understand a rule, prescribed by the sovereign power of a state to its citizens or subjects, declaring some right, enforcing some duty, or prohibiting some act. It is its general applicability, which distinguishes it from a single edict, or temporary and fugitive order of the sovereign will. It is supposed to furnish a permanent and settled direction to all who are embraced within its scope. It is not a sudden executive direction, but an annunciation of what is to govern and direct the rights and duties of the persons to whom it applies, in future. The rule being prescribed, it becomes the guide of all those functionaries who are called to administer it, and of all those citizens and subjects upon whom it is to operate. Neither is supposed to be at liberty to vary its obligations, or evade its provisions. But as, in the ordinary course of affairs in free governments, every person has a right, where the matter admits of judicial discussion, to litigate the question, what are the true object and meaning of a law, and how far it bears upon his rights, privileges, or duties,—it is understood, that in free governments, and especially in republics, the ultimate adjudication of what the law is, and how far it applies to a given case, is to be definitively settled by the judicial department of the government. It would be obviously unfit for the legislative department to settle retrospectively, as to past cases, what was its own meaning, its true office being to prescribe rules for the future. And though the executive department may, in the first instance, settle for itself what the law requires, its decisions cannot, and

ought not to be final; for it has no means to call the proper parties before it to litigate the question, and no power to decree any judgment. Its proper function is to administer the law, and not to make it; to act upon its true construction, and not to fix it. Otherwise, the fundamental principle of a republican government would be overturned; and laws would be, not settled rules of action to be judged of by courts upon the litigation of parties, deriving their rights from, or in opposition to them; but would be arbitrary decisions of the sovereign power, without appeal and without inquiry. In the American states, this principle is thought so fundamental, that their constitutions of government expressly separate the legislative, executive, and judicial departments from each other, and assign to each appropriate duties. It is thought that in no other way can the private rights and the public liberties of the people be secure. A departure from this doctrine would be deemed a direct advancement towards despotism. When, then, in Britain, it is asked what the law is, we are accustomed to consider what it has been declared to be by the judicial department, as the true and final expositor. No one is at liberty to disregard its exposition. No one is deemed above or beyond its reach, as thus declared. If it is supposed to be misconstrued, or rather not to carry into full effect the legislative will, a new or declaratory law is passed, and furnishes the appropriate remedy. And this leads us to remark, that the difference between civilians and common lawyers, in respect to the value and obligatory force of former decisions (which we call *precedents*), is most important. The opinion of no jurist, however high and distinguished is his reputation or ability, is of the least importance in settling the law, or ascertaining its construction. So far as he may, by his arguments, or comments, or learning, instruct the court, or enlighten its judgments, they have their proper weight. But if the court decide against his opinion, it falls to the ground. It has no farther effect. The decision becomes conclusive and binding, and other courts are governed by it, as furnishing for them the just rule of decision. No court would feel itself at liberty to disregard it, unless upon the most urgent occasion, and when it interfered with some other known rule or principle. And even then, with the greatest caution and reluctance. In countries where the common law prevails, it is deemed of infinite importance, that there should be a fixed and certain rule of decision, and that the rights and property of the whole community should not be delivered over to endless doubts and controversies. Our maxim, in truth, and not in form merely, is, *Miseræ est servitùs, ubi jure est vagum et incertum*. All this, it seems, is different in the civil law countries. There, the celebrity of a particular jurist may introduce a decisive change in the rule, or at least in the administration, of the law; and even different schools of opinion may prevail in different ages. Precedents have not, as with us, a final operation and value; and judicial tribunals consider, that a prior decision governs only the particular case, without absolutely fixing the principle involved in it. The practice under the common law has been found to be very beneficial; and experience having given it a sanction and value which supersede all theory and reasoning about it, it is not often that the matter is discussed upon abstract or philosophical views. But there are many grounds, which might be urged in support of this practice, which are capable of vindicating it as the most philosophical discussions. The question, in its most general form, must involve this import. What is best for society, with a view to its happiness, its security, its permanency? Now, it may not be

irrelevant to remark, that in every modern government, practically free, the common law rule has prevailed by general consent; and in those of the American states which were formerly under the civil law jurisdiction, there has been no desire ever expressed to retain their own rule. On the contrary, the common law rule has been eagerly adopted. It is not our purpose to enter into a review of all the grounds on which the common law rule might be vindicated; but there are one or two which deserve attention. In the first place, the rule has the advantage of producing certainty as to rights, privileges, and property. In the next place, it controls the arbitrary discretion of judges, and puts the case beyond the reach of temporary feelings and prejudices, as well as beyond the peculiar opinions and complexional reasoning of a particular judge; for he is hemmed round by authority on every side. In the next place, the consciousness that the decision will form a permanent precedent, affecting all future cases, introduces necessarily great caution and deliberation in giving it. If the case only were to be decided, it might be disposed of upon sudden impressions, and upon circumstances of hardship or compassion, or kindness, or special equity. But as the principles involved in it are to govern all future cases, and those principles must be derived from other analogies of the law, and be consistent with them, there are very strong restraints upon the judgment of any single judge. And there can be no permanent evil attendant upon any adjudications of this sort; for the legislative power may always apply the proper amendatory corrective at its will. And if the judges are actuated by corrupt motives, they may be removed by impeachment. It is no small proof that the system works well, that, in the course of many ages, very few decisions (comparatively speaking) have been overturned by the courts themselves, and that the legislature has not often found it necessary to change the rule prescribed by the courts. In fact, positive laws have been amended a hundred times, by the legislature, where one judicial rule has been interfered with. The changes which have been wrought in the fabric of the laws, have not so much arisen from misapplication of principles by the courts, as from the new state of society having rendered the old institutions and laws inexpedient or inconvenient. The circumstances which have been thus alluded to, have introduced a general and settled course of interpreting the laws, in countries governed by the common law. No such thing is known, in American jurisprudence, as a philosophical, or historical, or practical school of interpretation. There the laws are not subject to any varieties of interpretation grounded upon the present predominance of either of them. Certain maxims were early adopted, and they have never been departed from. Supplementary and auxiliary maxims of interpretation have necessarily been introduced. But, when once incorporated into the system, they have been deemed conclusive and obligatory. The sense of a law once fixed by judicial interpretation, is for ever deemed its true and only sense. Among the rules of interpretation belonging to and fixed in the common law, we shall enumerate a few, some of which, indeed, may be truly said to belong to the universal elements of rational jurisprudence. It is, perhaps, the exactness and uniformity with which they are applied, by judicial tribunals, which give them their principal value.

Laws may be divided into the following classes: **declaratory laws**; **directory laws**; **remedial laws**; and **prohibitory and penal laws**. **Declaratory laws** only declare what the law shall be, not what it has been, or is; how it shall govern rights in future, not how

it shall act upon the past. **Directory laws** are those which prescribe rules of conduct, or limit or enlarge rights, or point out modes of remedy. **Remedial laws** are those whose object it is to redress some private injury, or some public inconvenience. **Prohibitory and penal laws** are those which forbid certain things to be done or omitted, under a penalty, or vindictory sanction. In the nature of things, there is not any indispensable reason why the same rule should be uniformly applied in the interpretation of all of these different sorts of laws. We shall see that the common law allows some distinction in this respect. The fundamental maxim of the common law, in the interpretation of statutes, or positive laws, is, that the intention of the legislature is to be followed. This intention is to be gathered from the words, the context, the subject matter, the effects and consequences, and the spirit or reason of the law. But the spirit and reason are to be ascertained, not from vague conjecture, but from the motives and language apparent on the face of the law. 1. In respect to words, they are to be understood in their ordinary and natural sense, in their popular meaning and common use, without a strict regard to grammatical propriety or nice criticism. But the ordinary sense may be departed from, if the context or connexion clearly requires it; and then such a sense belonging to the words is to be adopted as best suits the context. 2. Again: terms of art and technical words are to be understood in the sense which they have received in the art or science to which they belong. 3. If words have different meanings, and are capable of a wider or narrower sense, in the given connexion, that is to be adopted which best suits the apparent intention of the legislature, from the scope or the provisions of the law. 4. And this leads us to remark, that the context must often be consulted, in order to arrive at a just conclusion, as to the intent of the legislature. The true sense in which particular words are used in a particular passage, may be often determined by comparing it with other passages and sentences, when there is any ambiguity, or intricacy, or doubt, as to its meaning. 5. And the professed objects of the legislature in making the law often afford an excellent key to unlock its meaning. Hence resort is often had to the preamble of a statute, which usually contains the motives of passing it, in order to explain the meaning, especially where ambiguous phrases are used. 6. For the same purpose, the subject matter of the law is taken into consideration; for the words must necessarily be understood to have regard thereto, and to have a larger or narrower meaning, according as the subject matter requires. It cannot be presumed, that the words of the legislature were designedly used in a manner repugnant to the subject matter. 7. The effects and consequences must also be taken into consideration. If the effects and consequences of a particular construction would be absurd, and apparently repugnant to any legislative intention deducible from the objects or context of the statute, and another construction can be adopted, which harmonizes with the general design, the latter is to be followed. But in all such cases, where the effects and consequences are regarded, they are not permitted to destroy the legislative enactment, or to repeal it, but simply to expound it. If, therefore, the legislature has clearly expressed its will, that is to be followed, let the effects and consequences be what they may. But general expressions, and loose language, are never interpreted so as to include cases which manifestly could not have been in the contemplation of the legislature. 8. The reason and spirit of the law are also regarded; but this is always in subordination to the words, and not to control the

natural and fair interpretation of them. In short, the spirit and the reason are derived principally from examining the whole text, and not a single passage; from a close survey of all the other means of interpretation, and not from mere private reasoning as to what a wise or beneficent legislature might or might not intend. Cases, indeed, may readily be put, which are so extreme, that it would be difficult to believe that any rational legislature could intend what their words are capable of including. But these cases furnish little ground for practical reasoning, and are exactly of that class, where, from the generality of the words, they are capable of contraction or extension, according to the real objects of the legislature. These objects once ascertained, the difficulty vanishes. This natural, and sometimes necessary limitation upon the use of words in a law, we often call construing them by their *equity*. In reality, nothing more is meant, than that they are construed in their mildest, and not in their harshest sense, it being open to adopt either. 9. For the same purpose, in the common law, regard is often had to antecedent and subsequent statutes upon the same subject; for being in *pari materia*, it is natural to suppose, that the legislature had them all in their view in the last enactment, and that the sense which best harmonizes with the whole, is the true sense. 10. For the like reason words and phrases in a statute, the meaning of which has been ascertained (especially in a statute on the same subject), are, when used in a subsequent statute, presumed to be used in the same sense, unless something occurs in it to repel the presumption. 11. As a corollary from the two last rules, it is a maxim of the common law, that all the statutes upon the same subject, or having the same object, are to be construed together as one statute; and then every part is to be taken into consideration. 12. Another rule is, to construe a statute as a whole, so as, if possible, or as nearly as possible, to give effect, and reasonable effect, to every clause, sentence, provision, and even word. Nothing is to be rejected, as void, superfluous, or insignificant, if a proper place and use can be assigned to it. 13. If a reservation in a statute be utterly repugnant to the purview of it, the reservation is to be rejected; if the preamble and the enacting clauses are different, the latter are to be followed. But the reservation may qualify the purview, if consistent with it, and the preamble control the generality of expression of the enacting clauses, if it gives a complete and satisfactory exposition of the apparent legislative intention. 14. The common law is also regarded, as it stood antecedently to the statute, not only to explain terms, but to point out the nature of the mischief, and the nature of the remedy, and thus to furnish a guide to assist in the interpretation. In all cases of a doubtful nature, the common law will prevail, and the statute not be construed to repeal it. 15. Hence, where a remedy is given by statute for a particular case, it is not construed to extend so as to alter the common law in other cases. 16. Remedial statutes are construed liberally; that is, the words are construed in their largest sense, so far as the context permits, and the mischief to be provided against justifies. By remedial statutes, we understand those whose object is to redress grievances, and injuries to persons, or personal rights and property, in civil cases. Thus, statutes made to suppress frauds, to prevent nuisances, to secure the enjoyment of private rights, are deemed remedial. 17. So statutes are to be construed liberally which concern the public good; such as statutes for the advancement of learning, for the maintenance of religion, for the support of the poor, for the institution of charities. 18. The general rule is, that the sovereign or government is not included

within the purview of the general words of a statute, unless named. Thus, a statute respecting all persons generally, is understood not to include the king. He must be specially named. But, nevertheless, in statutes made for the public good, which are construed liberally, the king, although not named, is often included by implication. 19. On the other hand, penal statutes, and statutes for the punishment of crimes, are always construed strictly.—The words are construed most favourably for the citizens and subjects. If they admit of two senses, each of which may well satisfy the intention of the legislature, that construction is always adopted which is most lenient. No case is ever punishable, which is not completely within the words of the statute, whatever may be its enormity. No language is ever strained to impute guilt. If the words are doubtful, that is a defence to the accused; and he is entitled, in such a case, to the most narrow exposition of the terms. This rule pervades the whole criminal jurisprudence of the common law, and is never departed from under any circumstances. It is the great leading principle of that jurisprudence, that men are not to be entangled in the guilt of crimes upon ambiguous expressions. But it is not to be understood, that the statute is to be construed so as to evade its fair operation. It is to have a reasonable exposition, according to its terms; and, though penal, it is not to be deemed odious. 20. Private statutes, also, generally receive a strict construction; for they are passed at the suggestion of the party interested, and are supposed to use his language. 21. Statutes conferring a new jurisdiction, and, especially, a summary jurisdiction contrary to the general course of the common law, are construed strictly. They are deemed to be in derogation of the common rights and liberties of the people under the common law, and are on that account jealously expounded. There are many other rules, of a more special character, for the construction of statutes, which the extreme solicitude of the common law to introduce certainty, and to limit the discretion of judges, has incorporated into maxims. But they are too numerous to be dwelt upon in this place. They all, however, point to one great object—certainty and uniformity of interpretation; and no court would now be bold enough, or rash enough, to gainsay or discredit them. On the contrary, it is the pride of our judicial tribunals constantly to resort to them for the purpose of regulating the necessary exercise of discretion in construing new enactments. The legislative power of a government is generally co-extensive with its sovereignty; and therefore embraces every thing which respects the concerns of the society. But it is in fact employed, if not universally, at least generally, in mere acts of amendment and supplement to the existing laws and institutions. Its office is ordinarily not so much to create systems of laws, as to supply defects, and cure mischiefs in the systems already existing. The question is often discussed in our day, how far it is practicable to give a complete system of positive law, or a complete code of direct legislation. And, if practicable, the farther question arises, how far it is desirable, or founded in sound policy. These questions have been the subject of ardent controversy among the civilians and jurists of the continent of Europe, living under the civil law; and, as many will be supposed, different sides have been taken by men of distinguished ability and learning; and the controversy is, and probably for a long period will be, pursued with great animation and powers of reasoning. In the countries governed by the common law, and especially in England and America, the same questions have been matter of wide discussion among the legal profession, as well as among statesmen, and

a great diversity of opinion has been exhibited on the subject. It will be our object, in the sequel of these remarks, to put the reader in possession of some of the main grounds of the controversy. The legislation of no country, probably, ever gave origin to its whole body of laws. In the very formation of society, the principles of natural justice, and the obligations of good faith, must have been recognised before any common legislature was acknowledged. Debts were contracted, obligations created, property, especially personal property, acquired, and lands cultivated, before any positive rules were fixed, as to the rights of possession and enjoyment growing out of them. The first rudiments of jurisprudence resulted from general consent or acquiescence; and when legislation began to act upon it, it was rather to confirm, alter, or add to, than to supersede, the primitive principles adopted into it. We, in fact, know of no nation, or, at least, of no civilized nation, whose history has reached us, in which a positive system of laws for the exigencies of the whole society was co-eval with its origin; and it would be astonishing if such a nation could be found. Nations, in their origin, are usually barbarous or rude in their habits, customs, and occupations. They are scanty in population and resources, and have neither the leisure, nor the inclination, nor the knowledge, to provide systems for future use, suited to the growing wants of society, or to their own future advancement in the arts. A few positive rules suffice, for the present, to govern them in their most pressing concerns; and the rest are left to be disposed of according to the habits and manners of the people. Habits soon become customs; customs soon become rules; and rules soon fasten themselves as firmly upon the existing institutions, as if they were positive ordinances. Wherever we trace positive laws, in the early stages of society, they are few, and not of any wide extent; directions for special concerns, rather than comprehensive regulations for the universal adjustment of rights. No man can pretend that, in Asia, any such universal rules were established by positive legislation, at the origin of the great nations by which it is peopled. The instructions of Moses, as promulgated by divine authority, for the government of the Jews, are not (as every one perceives) designed for every possible exigency of contract, or right, or injury, or duty, arising in the course of the business and history of that wonderful people. They are rather positive precepts, adapted to great occasions, and to govern those concerns which respected their wants, their spiritual advancement, and their duties as the chosen people of God. The Greeks are not known to us, in their early or later history, as having had a code of universal extent. The Romans, in their early history, had few positive laws; and those seem to have been borrowed from other sources. We often, indeed, see it stated, that the common law of England was originally formed from statutes now obsolete and unknown. But this assertion is wholly gratuitous. There is no reason to suppose that, in the early history of its jurisprudence, more was done than is usual in other nations, at the same period of their progress, such as the promulgating of some leading regulations, or the forming of some great institutions for the security of the public. In fact, a great portion of the English common law is of modern growth, and can be traced distinctly to sources independent of legislation. The common law of England is not two centuries old, and scarcely owes any thing important to positive legislation. In truth, the formation of codes, or systems of general law, for the government of a people, and adapted to their wants, is a business which takes place only in advanced stages of society, when knowledge is considerably diffused, and legis-

lators have the means of ascertaining the best principles of policy and the best rules for justice, not by mere speculation and theory, but by the results of experience, and the reasoning of the learned and the wise. Those codes with which we are best acquainted, are manifestly of this sort. The institutes, and pandects, and code of Justinian, were made in the latter ages of Roman grandeur—nay, when it was far on the decline,—not by instituting a new system, but by embodying the maxims, and rules, and principles, which the ablest jurists had collected in different ages, and from all the various lights of reason, and juridical decision, and general experience. No man imagines that Rome, in her early history, was capable of promulgating, or of acting upon, such a system. And this system, large as it was, has no pretension to be deemed complete, even for Rome itself. It left an infinite number of human concerns undecided by its text, which were, of course, to be submitted to judicial decision, and to receive the judgment of the wise men, who should be called, from time to time, to declare the law *ex æquo et bono*. It may indeed be assumed, as a general truth, that the body of every system of law which has hitherto governed human society, had its origin as customary law; and if it has ever assumed the form of positive legislation, it has been to give it greater sanctity and extent, as well as greater uniformity of operation. This is certainly true in respect to the common law. That system, as administered in Britain and the United States, is, as compared with the positive code, or statutes, of an immeasurably wider extent, both in its principles and its practical operation. A man may live a century, and feel (comparatively speaking) but in few instances the operation of statutes, either as to his rights or duties; but the common law surrounds him, on every side, like the atmosphere which he breathes. Returning, then, to the question before stated, it may be inquired, whether it be practicable, in a refined and civilized state of society, to introduce a positive code, which shall regulate all its concerns. That such a code could be formed in a rude or barbarous age, so as to be adapted to all their future wants and growth, in passing from barbarism to refinement, seems absolutely incredible. That it could be formed in a refined age, when learning, and large experience, and enlightened views, and a sagacious forecast, might guide the judgments of the legislature, is the point before us. In the first place, it has never yet been done by any people, in any age. The two most illustrious instances of codification are that of Justinian and that of Napoleon. Neither of these purports to be a complete system of laws and principles, superseding all others, and abolishing all others. As far as they go, they purport to lay down positive rules to guide the judgment of all tribunals, in cases within them. But other cases are left to be decided as they may arise, upon such principles as are applicable from analogy, from reasoning, from justice, from the customary law, or from judicial discretion. A positive prohibition to decide in cases not provided for by these codes, is not contained in either. But is it possible to foresee, or to provide beforehand, for all such cases? Society is ever varying in its occupations and concerns, in its objects and its pursuits, in its institutions, its pleasures, its inventions, its intelligence, and, in short, in innumerable relations and diversities of measures and means. How is it possible to foresee, or to limit, these relations or diversities? How is it possible, especially in free governments, to reduce all human acts to the same positive elements? to prevent contracts, and obligations, and rights, and equities, and injuries, and duties, from becoming mixed up in an infinite series of permutations and combinations?

Until it has been ascertained what are the utmost limits of human relations, and those limits, with all their intermediate details, can be clearly defined, in every shade of difference, how can any system of laws be adequate to provide for, or to guard them, or to fix the rights growing out of them? To suppose that man is capable of all this, is to suppose that he is omniscient, all-wise, and all-powerful; that he is perfect, or that he can attain perfection; that he can see all the future in the past, and that the past is present to him in all its relations. The statement of such a proposition carries with it its own refutation. While man remains as he is, his powers, and capacities, and acts, must forever be imperfect. But it may be said, that a positive code may be framed, and a declaration made that it shall be deemed the sole guide and rule, and that all other rules shall be prohibited. Certainly this may be done. But the effect of this would be, not to form a perfect code for all the future exigencies of society; but to declare that whatever was left unprovided for in the code, should be neither matter of right nor wrong. It would be to declare, that, as to all other transactions, now and hereafter, society should be utterly lawless; and, of course, it would be to declare, that a system confessedly imperfect, and not meeting the wants or exigencies, the rights or the wishes of society, should still govern it. What would this be, but to provide a bad code for human concerns, which it could not measure or manage? From these considerations, we may assume it as a concession granted on all sides, that a perfect code, to regulate all present, and, *a fortiori*, all future concerns of any civilized society, by positive rules, applicable to them, is morally impossible. The only real question is, whether a positive code can be provided, adequate, in a general sense, to the present known wants of society. That codes may be formed, more or less comprehensive, to regulate many or few concerns, to supply defects, or to give symmetry and order to the law on particular subjects, cannot be doubted. It has been often done. Perhaps no civilised nation has ever existed, in which there was not, at the same time, a written and an unwritten law, or, in other words, a rule of positive institution, and a rule of customary law. All special decrees and ordinances of the sovereign power are of the former kind. Many subjects are of such a nature as to require some positive rule, seeing that natural law cannot fix them upon any invariable basis. For example, there is nothing in the nature of things by which we can say, that land shall, in all possible states of society, descend to the possessor's heirs, or who those heirs shall be; that he shall have a right to dispose of them by testament or deed, and how that testament or deed shall be evidenced; whether bills of exchange and promissory notes shall be negotiable or not, and to what extent binding upon the parties. These subjects, in the origin of society, must either be positively provided for, or no rights can exist (strictly speaking) until they have become, by usage, fixed in a particular form. But most nations, with whose history we are acquainted, have had many positive laws. And to suit their institutions to the exigencies of society, in all its changes, there must be ordinances to change the old and to frame new rules. In ancient Rome, in the modern governments of continental Europe, and especially in France and in Britain, great alterations have, from time to time, been made in the existing system of laws. Fundamental laws have been abrogated; amendatory provisions have been established; existing rules have been methodised, confirmed, explained, and limited; and new rules prescribed for new cases. The ordinances of Louis XIV., of 1673 and 1681, on the subject of maritime

and commercial affairs, are striking instances of this sort. The abolition of feudal tenures; the regulation of uses and charities; the allowance of last wills and testaments, made in a prescribed mode; the provisions to suppress frauds, in the statute of frauds; the registration of conveyances of lands; the negotiability of promissory notes; and, above all, the positive enactments, various and almost innumerable, in the criminal code, are illustrations of the same fact, in the history of British legislation. All these statutes furnished, to a limited extent, a code on the particular subject. And we have recently seen, in the consolidation of the criminal laws of England into a few statutes, under the auspices of Sir Robert Peel, a striking instance of substantive codification of the criminal law of England, in many of its most important provisions. But the objections often urged against codes, are not meant to be applied to legislation of this sort, but to systems, which are promulgated for the government of the great concerns of nations, in all their various departments and interests. How far this can be done, has been a matter of considerable theoretical discussion. But the question has been practically answered by the existence of several positive codes. And among these whose success and wisdom have been most generally acknowledged, are the code of Justinian, and the code of Napoleon. That either of them furnishes complete rules for all the concerns of society, or excludes the necessity of judicial interpretation, or positive legislation, cannot be affirmed. That each of them covers a vast mass of the ordinary concerns of society, and fixes, positively and clearly, a great many wrongs and rights, and points out the proper redress, in cases where rights are to be vindicated and wrongs repressed, cannot well be denied. The question, then, is fairly presented, how far codes of this sort (the only ones which, in the actual state of society, are morally possible), are desirable, and founded in sound policy. It is here, that the advocates and the opponents of codes, under the jurisprudence of the common law, meet on debatable ground. The lovers of ancient institutions, of existing laws, of customary principles, oppose codes as inconvenient and unnecessary. They hold them to be inconvenient, because they fix a stubborn rule, which dis govern future cases, instead of leaving them open to the free operations of the common law, which adapts itself to all the circumstances of the age. They maintain, also, that codes are unnecessary; for, so far as there is any rule, it is already known in the common law; and positive legislation cannot make it more so. It is added (and it is true), that law is gradually formed, and must differ in different ages, according to the different circumstances of society; that it must be varied according to the progress or regress of a nation; that it can rarely settle comprehensive principles; and must, by degrees, thread its way through the intricacies of human actions; and that no inflexible rule might work quite as much mischief as now at all; that no legislature can make a system better just, or perfect, or harmonious, both from want of time, and experience, and opportunity of knowledge, as judges, who are successively called to administer justice, and gather light from the wisdom of their predecessors. Most, if not all, of these suggestions, may be admitted to be correct, and yet they do not settle the controversy. In the first place, the objectors must admit, that, under the common law, there are positive statutes, which regulate many great concerns and rights of the countries governed by it. The descent and distribution of real estates, the making of last wills and testaments, the forms and ceremonies attendant upon conveyances of real estates, to say nothing of other important subjects, are po-

vided for by positive statutes. Here we have a rule, which is absolute and inflexible. To say that, if found inconvenient, it may be altered, is, in effect, no argument at all; for the same may be said as to any provision of a systematic code. No code is supposed to be unalterable. Again, if it be said, that the legislature may, and often does, in an early stage of society, fix great principles and institutions, and then leaves the rest to judicial decisions, and thereby shows its wisdom, the true answer is, that the same reasoning applies to all codes, however extensive, if they leave the judicial tribunals at liberty to decide upon new cases, not governed by, or necessarily included in, the terms of the code. So far as the legislature has laid down principles (whether more or less extensive is of no consequence), these govern; beyond them, all is left as before. Again, the common law is itself, as far as it goes, a system of rules. These rules are fixed, certain, and invariable, as to all cases falling within them. They are quite as unyielding as any code can be. When the common law has declared that the eldest son shall be the sole heir, and that the half-blood shall not inherit, a court has no more liberty to depart from these rules, or to refuse to apply them to any case falling within them, upon any notion of hardship or inconvenience, or ill adaptation to the exigencies of society, than it has a right to say, that a last will and testament shall be good, though not executed according to the requirements of a statute. In each case, it is bound, and bound to the same extent. If the question were, whether a positive code should contain a clause prohibiting courts of justice from deciding upon cases not within the purview of the code, there might be much to urge against the policy and reasonableness of such a clause; but it would furnish no objection to other parts of the code. The only point, with reference to a code, which, under this aspect, would deserve consideration, is, how far it would be desirable to provide for cases which may be foreseen, but have not, as yet, actually been subjected to legislative decision. On one side, it may be said, that it would be best to leave all such cases to be decided, as they arise, upon the result of human experience and human judgment, then acting upon all the circumstances. On the other hand, it may be said, that it is better to have a fixed, present rule, to avoid litigation, and to alter it in future, if unexpected inconveniences should arise. The reasoning on each side is sound, when applied to particular cases. On each side, it admits of question, when applied to all cases. It may be best, in many cases, to leave the rule to be made, when the case arises in judicial controversy. In others, it may be far better to establish a present rule, to clear a present doubt, or fix a limit to what is now uncertain. Take the case of a bill of exchange, or promissory note; and suppose the question were, at what time demand of payment should be made, when it was payable on time, and no rule existed, and yet there was an immense amount of property dependent upon having a fixed, uniform rule; and, until so fixed, there must be endless litigation. Can any one doubt of the benefit of a rule, such as is now fixed in the commercial law of our country, for the purpose of securing certainty, viz. that payment must be demanded on the day on which it becomes due. On the other hand, suppose it were now proposed to make a law, fixing what should be the rate of wages in all future times, in all private employments; would it not, at once, occur to be impolitic to act upon a rule, the effects of which might immediately, or in future, press unequally and injuriously upon different interests in society? Again, it is said to be unnecessary to reduce the rules of the common law to a code, for they are as certain

now as they would be in a positive code. They are even more so, because the legislature cannot be presumed able to lay down a positive rule, with all the limitations and qualifications of the common law. Now, both of these suggestions admit of a satisfactory answer. If the rule exists, and has certainty in the common law, it can be stated. If there are any known exceptions, limitations and qualifications, upon a rule, those also can be stated. If nothing beyond a particular limit is known, then legislation can, at least, go to that limit. And as to all other cases, the same uncertainty exists, both at common law and in legislation. The difficulty of the argument consists in assuming, that, because the legislature has prescribed the same rule as the common law, the courts are thereby prohibited from doing what they possessed the power to do before, in the absence of any rule, viz. to find out what is the rule that ought to govern. Now, the legislature may as well leave this power in the courts, after a code, as the common law; and it will be best, unless there is a positive prohibition to the contrary. The other part of the suggestion applies only to the point, whether the code is well or ill formed by the legislature. If badly formed, it will, of course, be proportionally bad; but that furnishes no objection to a code, but to the mode in which it is executed. Then, again, as to the suggestion that it is unnecessary, because the rule already exists in the common law, and has certainty: to this several answers may be given. In the first place, if it be conceded, that there is entire certainty in the rule, at common law, there can be no harm in making the rule positive. It may do good; for it will instruct many, in and out of the profession, in respect to their rights and duty, who are now sadly ignorant of both, or are liable to be misled by their imperfect inquiries, or their limited sources of information. Every man may be able to peruse a concise text; but every man may not have leisure or ability to study a voluminous commentary. Besides, even in relation to the doctrines of the common law, many of them lie scattered in different cases, and many of them are not so clear as not to admit of different interpretations, by minds of different learning and ability. Even lawyers of great research and accuracy, especially where the doctrine, though on the whole clear, is matter of deduction and inference, may not, at once, come to the correct conclusion; and others of less learning and ability may plunge into serious errors. Now, it would be no small gain to have a positive text, which should give, in such cases, the true rule, instead of leaving it open to conjecture and inference by feeble minds. Again, there are many subjects of great intricacy and complexity, which can be fully mastered only by very able minds, resting, as they do, upon nice, and sometimes, upon technical reasonings, not seen by the common reader. In such cases, the text may admit of very exact statement, but the commentaries necessary to deduce it, may be exceedingly elaborate. The demonstration, or last result, may be clear, but the steps in arriving at it, exceedingly perplexed and embarrassing. It may require an analysis by the greatest minds to demonstrate; but, when once announced, it may be understood by the most common minds. For instance, the subject of contingent remainders and executory devises is of uncommon complexity in the common law, and many a lawyer may read Mr Fearn's admirable treatise on the subject, without feeling competent to expound all its doctrines. And yet, put every principle into a positive text, with all its limitations and restrictions (not to be made out by argument and inference, but given in a direct form), and his labours and his reasoning would be materially abridged, and cer-

tainty exist where darkness before overshadowed his mind. Again, the common law has now become an exceedingly voluminous system; and as its expositions rest, not on a positive text, but upon arguments, analogies and commentaries, every person, who desires to know much, must engage in a very extensive system of reading. He may employ half his life in mastering treatises, the substance of which, in a positive code, might occupy but a few hundred pages. The codes of Justinian, for instance, superseded the camel-loads of commentaries, which were anteceded in use, and are all now buried in oblivion. The Napoleon codes have rendered thousands of volumes only works of occasional consultation, which were before required to be studied very diligently, and sometimes in repeated perusal. Again, what is to be done in the common law, where there are conflicting decisions on the same point, or converging series of opposite doctrines, approaching towards a conflict? The rule is here confessedly uncertain. Why should not the legislature interfere, in such a case, and fix a rule, such as, on the whole, stands upon the better reasoning and the general analogies of the law? In point of fact, this is often done. Declaratory laws, in form, are unusual among us; but laws to clear doubts and difficulties are very common. Such interferences ought, doubtless, to be made with caution and prudence, and great deliberation. But this furnishes no just objection to a reasonable exercise of the power. But in the practice under the common law, there is still stronger ground for interference. In the first place, what the common law is, is always open to question; and if authorities are suggested on either side, it is common enough to find the rule deduced from them, doubted, denied, or explained away, by parties in an opposite interest. Courts are bound to hear as well as to decide; and although a court may think the rule of the common law clear, from their own prior researches and reasoning, it will rarely feel at liberty to stop eminent counsel, when they deny the rule, or seek to overthrow the authorities and reasonings by which it is supported. The spirit of our tribunals, and the anxious desire, not only to do, but to appear to do justice, lead to a vast consumption of time in these discussions. If the legislature had once recognised the rule in a positive code, there would be an end of all such reasoning. The only question which could remain, would be, whether the rule were applicable to the case. In the next place, there are, upon some doctrines of the common law, a vast multitude of authorities to examine, compare, and understand, which requires not only great diligence, but great skill. In some cases, there are shades of difference fit for comment; in others, *obiter dicta*, which are to be qualified; in others, doubts thrown out upon collateral heads; in others, reasoning not altogether satisfactory. Under such circumstances, what is to be done? The advocate on the one side comments on every case, and the language of every judge, which furnishes any colour of support for his client. His arguments must be met and answered on the other side, not only because no advocate can know what the judges will decide, but what will be the influence upon their minds of a *dictum*, or doubt, or incidental remark or reason. It is indispensable, therefore, to examine the whole, though perhaps neither party doubts what the amount of authority, on the whole, supports. On one point (we believe) a learned English judge said, many years ago, that there were then more than 170 authorities. It is most probable that the number is now doubled; and yet, upon this very point, a legislative enactment of three lines might put controversy at rest for ever. Perhaps no man in or out of the legal

profession would now doubt what the rule ought to be. The difficulty is, that a rule has either been adopted which works inconveniently in particular cases, or a rule has grown out of a hasty adjudication, which subsequent judicial subtilty has been desirous of escaping from; but it is not easy to do so, without breaking in upon the acknowledged force of the rule. Hence distinctions, nice, and, perhaps, not very satisfactory, are found, as blemishes in some parts of the law, which need the legislative hand to extirpate or correct them. But it has been urged, as has been already incidentally noticed, that it is a great advantage to have law a flexible system, which will yield to the changing circumstances of society; and that a written code gives a permanence to doctrines, which would otherwise be subject to modification, so as to adapt them to the particular character of the times. This objection has been already in part answered. In respect to the common law doctrines, they cannot now be changed, whatever may be the changes of society, without some legislative enactment. They furnish a guide to all cases governed by them, until the legislature shall promulgate a new rule. Courts cannot disturb or vary them; and the question of their application to new cases is equally open, whether there be, or be not a code. The legislature can, with the same ease, vary its code as its common law. It can repeal, amend, or modify either. But another principal objection is often suggested, and that is, that all the parts of the common law are not in a state susceptible of codification; and that, as we cannot form a complete system of it, one great object of a code must fail. It may be admitted, that some parts of the common law are too imperfectly settled in principles, and too little understood in practice, to admit of any exact codification. But these parts are principally obsolete, or of rare occurrence and application in the common business of life; so that, if they admitted of being reduced to a text, it may be well doubted if they were important enough to deserve it. There are other parts, again, which have grown up in modern times, which may be admitted to be yet in an immature and forming state, in respect to which, perhaps, it were better to wait the results of experience, than to anticipate them by positive law. Conceding all this, it falls far short of establishing the inutility of a code in other departments of the common law, not open to the like objections. Because we cannot form a perfect system, does it follow that we are to do nothing? Because we cannot, without rashness, give certainty to all possible or probable details of jurisprudence, shall we leave every thing uncertain and open to controversy? England, in our own time, has consolidated the most important heads of her criminal jurisprudence, to a new and methodized text. No man can doubt, that revisions of this sort may be useful, and, indeed, indispensable for the wants and improvements of society, in its progress from one stage to another. The question of more or less is a mere matter of expediency and policy. It is not a little remarkable, that, in England, almost every change in the general structure of her laws, by positive legislation, has, in all ages, met with a similar objection and resistance, and, when once adopted, has been generally, if not universally satisfactory. But there are many branches of the common law which can, without difficulty, be reduced to a positive text. Their main principles are embodied in treatises, accurate and full, and there can be no want of learned men ready to draw an outline of them for the consideration of the legislature. Our commercial law is generally in this state. The law of bills of exchange and promissory notes, of insurance, of shipping and navigation, of

partnership, of agency and factorage, of sales, of bailments, and many kindred titles, admits of codification to a very high degree of certainty; and yet, in these branches, there is still room enough to controvert particular decisions and authorities, to make it desirable to give a positive sanction to the better doctrine, and thus to save the profession from laborious researches, and the public from expensive litigation. The ordinance of Louis XIV., on commercial law, dried up a thousand sources of disputation; and the present code of commerce of France has settled, in a positive manner, most of the questionable points, which had been found unprovided for by that ordinance, and were resigned to judicial decision in the intermediate period. Besides, a code furnishes the only safe means of incorporating qualifications upon a general principle, which experience has demonstrated to be proper and politic. Courts often lament that a principle is established in too broad terms for the public good, and yet do not feel themselves at liberty to interpose exceptions which the principle does not sanction. This article has already spread out into a great length, and must now be closed. The result of the whole view, as to codes, is, that neither the friends nor the opponents of them are wholly right in their doctrines or their projects; that, in every civilised country, much may be done to simplify the principles and practice of the law by judicious codification, and to give it uniformity and certainty; that How much ought to be done? is a question not admitting of any universal response, but is, or may be, different as to different countries, or, in different ages, as to the same country; that every code, to be useful, must act upon the existing institutions and jurisprudence, and not, generally, supersede them; that what, with reference to the customs, habits, manners, pursuits, interests, and institutions of one country, may be fit and expedient, may be wholly unfit and inexpedient for another; and that the part of true wisdom is, not so much to search out any abstract theory of universal jurisprudence, as to examine what, for each country in particular, may best promote its substantial interests, preserve its rights, protect its morals, and give permanence to its liberties.

LAW MERCHANT. See *Commercial Law*.

LAW OF EXCEPTION (in French, *loi d'exception*). When the situation of a state is so critical that the ordinary powers and laws are no longer considered sufficient, extraordinary and more energetic means are employed. The Romans had a form for such an emergency, which invested the two consuls with a greatly augmented power—"Videant consules, ne quid republica detrimenti capiat (Let the consuls see that the republic receive no injury);" and if this was not sufficient, they appointed a dictator. The remedy was often worse than the disease. Despotical governments require no laws of exception; in these the public power is always free from the restraints which are imposed upon it in constitutional states. In the latter, certain cases happen in which the power of the government must be strengthened, to be able to act with energy and promptness. In Britain, the first and most important regulation, in such an emergency, is the suspension of the *habeas corpus* act for a limited time. The government can then take into custody suspected and dangerous persons, without following the regular process of law. This suspension is not a prerogative of the crown, but can only be granted by parliament, and for a limited period, at the expiration of which all such state prisoners must be released, or subjected to a formal examination. Even then, the suspension does not protect the ministerial officers against the demands for indemnification for an unjustifiable arrest. These com-

plaints, when made against the ministers of the king, are usually comprehended in a separate act of parliament, called the *indemnity bill*, at the discussion of which in parliament, the opposition party is careful to institute a strict examination of the use which the ministers have made of their extraordinary power. A second regulation of this kind is the alien bill (see *Alien Bill*), which invests the government with a power over all foreigners dwelling in Britain, such as does not constitutionally belong to it, giving the right not only to order them out of the country at pleasure, but also to send them to any part of the continent. Bills of pains and penalties, which are admissible in single cases, constitute a sort of law of exception. Parliament maintains the right to pass such bills, which could not belong to it under a correct division of public power, and thus to punish individuals without a judicial sentence. This is to be distinguished from its proper judicial functions, by which the peers of the realm, the house of lords, act as the highest court of justice, and the house of commons comes forward as complainant (as in the case of governor Hastings). There the lords sit formally as a court of justice; a full judicial hearing is granted to the defendant, and his condemnation cannot be pronounced except by a majority of twelve voices (the number of the jury in usual cases). In these cases, the house of lords alone decides upon the motion of the commons, and wholly without the concurrence of the king, whose right to pardon is even circumscribed. But when an individual bill of attainder, or bill of penalties, is brought forward in parliament, then the introduction of the act may take place in the house of lords as well as in the house of commons; and no peculiar legal process is followed, but it depends on the pleasure of each house how the facts, upon which the summary sentence is grounded, shall be proved; and it is only from considerations of natural justice that opportunity is granted to the accused to defend himself. The sentence itself is passed by a simple majority of voices in each house, like other laws; but it must be sanctioned by both houses of parliament, and the assent of the king must be obtained, as in any other law. In fixing the punishment, also, parliament is amenable to no established rule, and the right of the king to pardon wholly ceases, if he has once given his consent. Such a process has always something very odious on the face of it, and, in point of fact, it is very rarely resorted to. Thomas Wentworth, earl of Stafford, the celebrated confidential minister of Charles I., was condemned to death by this form, and it was equally criminal and impolitic in the king to give his consent to this bill of attainder. The same process was introduced against the queen, in 1820, and, wholly independent of her guilt or innocence, this was a sufficient reason for rejecting it.

In the United States of America no such legislative power exists, either in the state or in the national legislature. It is contrary to the genius of a republican government. The constitution of the United States declares, that "No bill of attainder, or *ex post facto* law, shall be passed;" that "the privilege of the writ of *habeas corpus* shall not be suspended unless when, in cases of rebellion or invasion, the public safety requires it." So, also, except in cases of impeachment, every person accused of a capital or infamous crime, (except in the navy or army service) has a right to a trial by jury, and cannot even then be tried, unless upon a presentment or indictment by a grand jury. Such are the privileges guaranteed by the constitution of the United States. And the state constitutions generally embrace the same protective principles. There is also another principle recognised in the constitution of the United States, which is of great importance. It is the provision, that "exces-

sive bail shall not be required, nor excessive fines imposed, nor cruel and unusual punishments inflicted ;" so that, while the present republican constitutions of government exist in America, there can be no such thing as a dictatorship, or a law of exception.

In France, there was no occasion for laws of exception before 1790; the *lettres de cachet* (q. v.) answered all purposes. The parliaments, if they opposed the royal mandates, and prevented their publication, which consisted in entering them in the register of parliament, were at last brought to obedience by a royal session, or *lit de justice*, or by exile to some obscure place; or, if their resistance was obstinate, they were dissolved, as in the last years of Louis XV. But after the struggle for legal order, from want of moderation on both sides, had degenerated into a furious conflict of parties, the laws of exception were often really necessary, though often used merely as instruments of faction. We do not here refer to illegal, though perhaps necessary, measures (*coups d'état*) adopted in extraordinary cases, such as the dissolution of the legislative body on the 18th Fructidor, 1797, the abolition of the tribunate, 1807, &c. But the suspension of the constitution (even the democratical) by the committee of public safety, in 1793, and the rendering the revolutionary tribunal permanent, were genuine laws of exception. The regular administration of the laws was promised by every new government, but, down to the revolution of 1830, the promise was not fulfilled. The liberty of the press was repeatedly restrained, and the regular course of justice perverted by special tribunals. One of the most remarkable laws of exception was that of March 3, 1810, respecting the state-prisoners, by which the ancient *lettres de cachet* were again introduced in almost full force. It was required, indeed, that a warrant of the minister of justice, and a mandate of the privy council, should precede imprisonment, which was to continue no longer than a year; but a regulation, like the *Aubeas corpus* act in Britain, was wanting to enforce the performance of these conditions. Under the reign of Louis XVIII., also, numerous laws of exception were enacted, although the charter (art. 8th) declared, "The French have the right of publishing and printing their opinions, provided they conform to the laws against the abuses of the press." By repeated laws of exception, the censorship was extended not only over the political, but often even over the literary Journals. The assassination of the duke of Berry, in particular, was made the pretence for restricting the liberty of the press, for investing the ministers with authority to confine persons suspected of crimes, or of criminal designs against the king, the state, and the royal family, without a judicial process. These laws were to continue to the end of the session of 1820. The law concerning the censorship was renewed in the session of 1820, and till three months after the commencement of the session of 1821; but the law relating to the imprisonment of suspected persons was tacitly abolished. The last laws of exception in France were the famous ordinances of July, 1830, which resulted in the overthrow and expulsion of the Bourbons.

**LAW OF NATURE, and OF NATIONS.** See *National Law*, and *Natural Law*.

**LAW, JOHN**; a celebrated financial projector, was the son of a goldsmith of Edinburgh, in which city he was born in 1681. He was bred to no profession, but became versed in accounts and was employed in those of the revenue. For the purpose of remedying the deficiency of a circulating medium, he projected the establishment of a bank, with paper issues, to the amount of the value of all the lands in the kingdom; but this scheme was rejected. In

consequence of a duel, he fled from his country, and visited Venice and Genoa, from which cities he was banished, as a designing adventurer; but, at length, secured the patronage of the regent duke of Orleans, and established his bank in 1716, by royal authority. It was at first composed of 1200 shares of 3000 livres each, which soon bore a premium. This bank became the office for all public receipts, and there was annexed to it a Mississippi company, which had grants of land in Louisiana, and was expected to realise immense sums by planting and commerce. 1718, it was declared a royal bank, and the shares rose to twenty times their original value. In 1720, Law was made comptroller-general of the finances; but the shares sank in value as rapidly as they had risen. He was obliged to resign his post, after he had held it only five months, and to retire, first to a seat in the country, and then, for personal safety, to quit the kingdom. He carried with him a small portion only of the vast fortune he at one time possessed, and lived afterwards in great obscurity. After visiting Britain, Holland, Germany, and other countries, he finally settled at Venice, where he died in 1729, still occupied in vast schemes, and fully convinced of the solidity of his system, the failure of which he attributed entirely to enmity and panic. Various opinions have been entertained of the merit of his project; and by some it has been thought to have possessed feasibility, had it been carried more moderately into practice.

**LAW, WILLIAM**; a divine of the church of England, born at Kingcliffe, in Northamptonshire, in 1668, educated at Emanuel College, Cambridge, where he was elected fellow: On the accession of George I., refusing to take the oaths, he vacated his fellowship, and left the university. He then officiated as a curate in London, and as tutor to Edward Gibbon, father of the historian. Mrs Hester Gibbon, aunt of the same eminent individual, and Mrs Elizabeth Hutchinson, formed a joint establishment, of which he became a member, at his native village of Kingcliffe, where he died in 1761. The Writings of Mr Law, although in many respects excellent, partake of a gloominess and severity, tinged with a mysticism and enthusiasm, that the study of the writings of Jacob Bohme did not fail to increase. The Serious Call to a Devout and Holy Life, is deemed both by doctor Johnson and Mr Gibbon, one of the most powerful works of devotion in the English language, as is also his Practical Treatise on Christianity, which abounds with satire, spirit, and knowledge of life. He also wrote some other works, and published translations of his favourite Bohme. (See his *Life*, by Tighe, and Gibbon's *Memoirs* of himself.)

**LAWRENCE, Sir THOMAS**, a distinguished English portrait painter, was born at Bristol, in 1726. His father was an inn-keeper, and the artist very early exhibited proofs of his talent for the art: he is said to have sketched portraits very successfully at his fifth year. At the age of six, he was sent to school, where he remained two years; and this, with the exception of a few lessons subsequently, in Latin and French, constituted his whole education. His father would not even permit him to be instructed in drawing, declaring that his genius would be cramped by the restraint of rules. Young Lawrence, however, had access to the galleries of some of the neighbouring gentry, in which he employed himself in copying historical and other pieces. In 1738, his father removed to Bath, where his son was much employed in taking portraits in crayon; and, having made a copy of the Transfiguration, by Raphael, the society of arts bestowed on him their silver palette, in consequence of its merits. During six years, he was the sole support of his father and a large family. In

1787, the family removed to London, and Lawrence was admitted a student at the royal academy. His subsequent career was successful and brilliant. He was elected royal associate in 1791, and, on the death of Sir J. Reynolds, the next year, was made painter to the king. His reputation grew steadily, and he was soon considered the first portrait painter of the age in England. His scene from the *Tempest* was a successful attempt at historical painting; but that branch of the art receives too little encouragement in England, in comparison with that of portrait painting, to induce a successful artist, in the latter department, to cultivate the former. In 1815, he was knighted by the prince regent, who also employed him to take the likenesses of the sovereigns, and the most distinguished persons of their suite. During their visit to England, he finished the portrait of the king of Prussia, and went to Aix-la-Chapelle, several years afterwards, to paint Alexander; thence he went to Vienna, where he completed the portraits of the emperor, the archdukes, Metternich, &c., and, in Rome, painted Pius VII. and cardinal Gonsalvi. On his return to England, he was elected president of the royal academy, as successor to West. (q. v.) This office he held till his death, which occurred suddenly, Jan. 7, 1830. His portraits are striking likenesses, and display a bold and free pencil; but they are, particularly his later ones, chargeable with mannerism, and are not considered to be successful in expressing the nicer shades of character. In his drawing, there is a want of accuracy and finish. His income for the last twenty years of his life, was from £10,000 to £20,000; but he died poor, owing to his zeal to possess the first-rate productions of his art, which he purchased at any price. The personal appearance of Sir Thomas Lawrence was striking and agreeable. His countenance bore a marked resemblance to that of Canning, and he was always pleased when this resemblance was observed. He was studious in dress, and went beyond the limits of correct taste in this particular. A look of settled melancholy was always upon his features, and there was a restlessness in his manner that bespoke an unquiet spirit.

LAWRENCE, JAMES, a distinguished American naval commander, was born at Burlington, New Jersey, in 1781. He early manifested a strong predilection for the sea; but his father, who was a lawyer, was anxious that he should pursue his own profession; and, when only thirteen years of age, he commenced the study of the law; but after the death of his father, he entered the navy as a midshipman, in 1798. In 1801, the Tripoli war having commenced, he was promoted, and, in 1803, was sent out to the Mediterranean, as the first lieutenant of the schooner *Enterprise*. While there, he performed a conspicuous part in the destruction of the frigate *Philadelphia*, which had been captured by the Tripolitans. In the same year, he was invested with the temporary command of the *Enterprise*, during the bombardment of Tripoli by commodore Preble, all the ships of the squadron being employed to cover the boats during the attack; and so well did he execute his duty, that the commodore could not restrain the expression of his thanks. He remained in the Mediterranean three years, and then returned with Preble to the United States, having previously been transferred to the frigate *John Adams*, as first lieutenant. In June, 1812, war was declared between Great Britain and the United States, and Lawrence, at the time in command of the *Hornet*, a few days afterwards sailed with a squadron under the orders of commodore Rogers, for the purpose of intercepting the Jamaica fleet. They returned, however, at the end of the following month, to Boston, without having been able to accomplish their object. Lawrence then accompanied commo-

dore Bainbridge on a cruise to the East Indies; but they separated near St Salvador, on the coast of Brazil, the *Hornet* remaining there to blockade a British ship of war, laden with specie, till compelled to retire by the arrival of a seventy-four. Feb. 24, 1813, the *Hornet* fell in with the brig *Peacock*, captain Peake, which she took after a furious action of fifteen minutes. This vessel was deemed one of the finest of her class in the British navy. In the number of her men and guns, she was somewhat inferior to the *Hornet*. She sank before all the prisoners could be removed. The latter was considerably damaged in the rigging and sails, but her hull was scarcely hurt. Lawrence returned to the United States, where he was welcomed with the applause due to his conduct; but the most honourable eulogy bestowed upon him, was contained in a letter, published by the officers of the *Peacock*, expressing their gratitude for the consideration and kindness with which they had been treated. Shortly after his return, he was ordered to repair to Boston, and take command of the frigate *Chesapeake*. This he did with great regret, as the *Chesapeake* was one of the worst ships in the navy. He had been but a short time at Boston, when the British frigate *Shannon*, captain Brocke, appeared before the harbour, and defied the *Chesapeake* to combat. Lawrence did not refuse the challenge, although his ship was far from being in a condition for action; and, June 1, 1813, he sailed out of the harbour, and engaged his opponent. After the ships had exchanged several broadsides, and Lawrence had been wounded in the leg, he called his boarders, when he received a musket ball in his body. At the same time the British boarded, and after a desperate resistance, succeeded in taking possession of the ship. Almost all the officers of the *Chesapeake* were either killed or wounded. The last exclamation of Lawrence, as they were carrying him below, after the fatal wound, was, "Don't give up the ship." He lingered for four days in intense pain, and expired on the 5th of June. He was buried at Halifax, with every mark of honour.

LAWRENCE, St; a Roman deacon, and martyr, who, when his bishop, Sixtus, was led to death, cried out, "Whither dost thou go, father, without thy son?" The bishop ordered him to remain, and to take care of the treasures of the church; but he was arrested, and ordered to give up these treasures. He asked for three days' respite, during which he called together all the poor and sick, whom he showed to the satellites of the emperor, as those whose support secured treasure in heaven. The instrument of his martyrdom was a gridiron, on which he was burned to death, in 254. (See *Escorial*.) His day, in the Catholic church, is August 10.

LAWRENCE, St. This river, one of the largest in the world, is the outlet by which the waters of the great lakes Superior, Huron, Michigan, Erie, and Ontario, are poured into the ocean through the gulf of St Lawrence. In different parts of its course, it is known by different names. From the sea to lake Ontario, it is called *St Lawrence*; but the name *Cataqui*, or *Iroquois*, is sometimes applied to the part between Montreal and lake Ontario. Between lakes Ontario and Erie, it is called *Niagara* river; between lakes Erie and St Clair, *Detroit* river; between lakes St Clair and Huron, *St Clair's* river; between lakes Huron and Superior, *St Mary's* river, or the *Narrows*, forming thus an uninterrupted connexion of upwards of 2000 miles. It is navigable for ships of the line to Quebec, about 400 miles, and to Montreal for ships of 600 tons, 580 miles. The distance from Montreal to lake Ontario is 190 or 200 miles. The tide flows up as far as Three Rivers.

Its breadth between Montreal and Quebec is from half a mile to four miles; the average breadth, about two miles. Below Quebec, it gradually widens, till it enters the gulf, where, from Cape Rosier to the Mingan settlement, on the Labrador coast, it is about 105 miles in breadth. The country through which it flows, from the lake to the gulf, is generally fertile, and much of it well cultivated, and rapidly improving; on both sides, the prospect is delightful: numerous villages, for the most part built round a handsome stone church, invite the traveller's attention, while single houses and farms appear at agreeable distances. The river in several places spreads out into large lakes, as lake St Francis, St Louis, and Deux Montagnes; and there are numerous islands, shoals, and rapids. From the beginning of December to the middle of April, the navigation is totally suspended by frost. The breaking up of the ice in the spring is described as a magnificent scene.

**LAWRENCE, ST, GULF OF**; a gulf which receives the waters of the St Lawrence, formed between the western part of Newfoundland, the eastern shores of Labrador, the eastern extremity of New Brunswick, part of Nova Scotia, and the island of Cape Breton. It communicates with the Atlantic by three passages,—on the north, by the straits of Belleisle, between Labrador and Newfoundland; on the south-east, by the passage between Cape Ray and Newfoundland; and by the gut of Canso, which divides Cape Breton from Nova Scotia. The distance from Cape Rosier to Cape Ray is seventy-nine leagues; from Nova Scotia to Labrador, 106.

**LAY** (from the Anglo-Saxon word *ley*); the name of an ancient elegiac kind of French lyric poetry, formerly much imitated by the English. The *lay* is said to have been formed on the model of the trochaic verses of the Greek and Latin tragedies. There were two sorts of *lays*; the greater, which consisted of twelve couplets of verses, in different measures; and the lesser, comprising sixteen or twenty verses. The word *lay* is now generally applied to any little melancholy song or air, and is, for the most part, used in that sense by Chaucer, Spenser, Milton, Waller, Dryden, and other classical English poets.

**LAYBACH** (in Italian, *Lubianna*; in Illyrian, *Lublana*); capital of the Austrian duchy of Carniola, the seat of the chief imperial *gubernium*, in the kingdom of Illyria, for Carniola and Carinthia, also of a prince-bishop, &c. In ancient times, it was called *Æmona*, and was a considerable city in the Vindelician Illyria. It contains, at present, 866 houses, with 11,500 inhabitants, who speak German, Italian, modern Greek, and French. The lower class speak the Illyrian-Vindelician dialect, which differs little from the Croatian and Istrian. It carries on considerable commerce with Vienna, Venice, Bavaria, Constantinople. From 1809 to 1813, it was the residence of the French governor-general of the Illyrian provinces. The city has become remarkable, of late, on account of the congress held here, from January 26, 1821, to May of the same year. In the article *Congress*, the recent congressional politics, and the consequences of the congress at Laybach, are discussed. This congress forms a conspicuous epoch in the history of politics, as it was here that the right of armed intervention (see *Intervention*) was regularly proclaimed and received into the national law of Europe. Russia, Austria, and Prussia, declared that they would never abandon these principles, but the year 1830 made some change in their policy. Britain declared (Castlereagh's letter, January 19, 1821) that it could not agree to such principles.—See Bignon's *Du Congrès de Troppau* (Paris, 1821), and the articles *Italy, Sicily, The Two, and Sardinia*; see also the article *France, History of*.

**LAYMAN** (from the Greek *λαος*, people) signifies, since the third century, every person not a clergyman. —Among painters, it signifies a small statue, whose joints are so formed, that it may be put into any attitude, for the purpose of adjusting the drapery of figures.

**LAYNEZ, JAMES**, the second general of the Jesuits (q. v.), and the real founder of the policy and organisation of the society, was born at Almazan, near Siguena, in Castile, in 1512. He studied at Alcalá. The fame of Ignatius Loyola's religious era, and the desire of becoming acquainted with him, and, at the same time, of pursuing his own studies, led Laynez to Paris, where Loyola was then residing, in order to escape the persecution of the inquisition. An intimacy was soon formed between these two zealots, and they determined to go to Turkey, and preach the gospel to the infidels. A war with the Porte defeated this plan; and, while at Venice, in 1536, they formed the project of establishing a society, the principal aim of which should be the education of the people in the doctrines of the Roman church, and the prevention of the spread of the new opinions. Laynez, more prudent, learned, refined, and dexterous than Loyola, had the principal share in the formation of this plan, and his disinterestedness, his zeal, and activity, were the principal causes of the success of the new institution. After the order had been confirmed by Paul III. (1540), and Loyola, at the request of Laynez, had been appointed the first general, he made many journeys for the purpose of extending the society of the Jesuits, and exerted himself, with great activity, in the cause of the pope at the council of Trent. He refused the cardinal's hat, which was offered him by Paul IV. In 1558, he succeeded Loyola, as general of the order. In 1561, he went to France with the cardinal Ferrara, to assist him in extirpating heresy. Still we must do him the justice to say, that he was the only one at the notorious conference of Poissy, who listened at all to the voice of reason and mercy. The establishment of the Jesuits in France, although with some restrictions (see *Jesuits*), was the result of this journey. After Laynez had assisted in establishing, at the third council of Trent, the supremacy of the bishop of Rome over the other bishops, he returned to Rome, where he devoted himself to the direction and extension of his order. He died there January 19, 1565, at the age of fifty-three.

**LAZARETTO**; a public building, hospital or pest-house, for the reception of those afflicted with contagious distempers. It is more particularly applied to buildings in which quarantine is performed. See *Quarantine, Plague, Yellow Fever*.

**LAZARITES, or FATHERS OF ST LAZARUS**, in France; the priests of the mission were so called after their priory of St Lazarus, in Paris. This order, consisting of regular priests, bound by complete monastic vows, was established in 1634, for the purpose of supporting missions; but, in pagan countries, they have effected less than other orders established for the same purpose. In China, they have still a mission. In France, they survived the revolution, and, in 1816, were restored, by a royal ordinance, to their original destination, on account of their services in the care of the country people. Before July, 1830, they distinguished themselves as the most active missionaries, adherents, and reformers, in the service of the ultra-party; by means of which party, a portion of their former estates was restored to them. In Poland, where they are called *fathers of the mission*, they are most numerous, and have great influence, as teachers in the seminaries and as spiritual censors. They maintain their ancient monasteries, and the backward state of science, in that

country, is, in some measure, to be ascribed to their influence. In Spain, also, this order has flourished, though the influence of the Lazarites there has not been so great. Austria has admitted them more recently.

**LAZARUS**; the name of a leprous beggar mentioned in sacred history. (*Luke xvi, 20.*) The memory of a monk of this name, belonging to the ninth century, is celebrated by the Roman church (*Feb. 21*), because neither the threats nor the violence of Theophilus, emperor of Constantinople, could prevent him from painting images of the saints. The former afterwards became patron of the sick, particularly of lepers, and in Palestine was instituted the order of St Lazarus, whose members, called *knights hospitallers of St Lazarus of Jerusalem*, took care chiefly of persons afflicted with the leprosy. This disease was spread in Europe by the crusaders; and the hospitals, which, till the thirteenth century, were frequently established for lepers, received the name of *lazarettos*, which, at a later period, was extended to all hospitals. (q. v.)

**LAZULITE** is rarely found in perfect crystals, more often granular, or in pieces not exceeding the size of a hazel-nut. It is somewhat translucent, of a fine blue colour, of different shades; nearly as hard as quartz. Its primary form is a right rhombic prism; the direction of its cleavages has not been determined; specific gravity, 3.05. Before the blow-pipe, it intumesces a little, and assumes a glassy appearance, where the heat has been highest, but does not melt. It consists of phosphoric acid 41.81, alumine 35.73, magnesia 9.34, silice, 2.10, oxide of iron 2.64, and water 6.06. It is found in narrow veins, traversing clay-slate, with quartz, in Salzburg.

**LAZZARONI**; a class of persons in Naples (formerly about 40,000), without employment or home, and without any settled means of support, the greatest part of them living for the whole year, both day and night, in the streets and public places. The extreme fruitfulness of the soil, which renders subsistence very easy, the extraordinary temperance of the inhabitants, the warmth of the climate, and the indolence which it produces, have given rise to this class of men. The little which is absolutely necessary, they easily pick up, in the capacity of messengers, porters, and day-labourers, without hard work. Hence, in spite of their great number, they are extremely good-natured and peaceful, and mildly put up with insults and provocations from the other classes. In Naples is found every thing which can make such a life practicable; hence a *lazzarone* never leaves the city without the most pressing necessity. The desire of property and of more of the comforts of life, with more industrious habits, was first introduced among these people in modern times, under the reign of Joseph Bonaparte, when they were employed in making excavations, &c., and received part of their pay in domestic utensils and furniture, that they might become accustomed to a home. They were also collected in villages, where it was intended to educate their children. The police regulations of king Joachim (Murat) also contributed to improve their condition. The *lazzaroni* consisted at first principally of sick persons from the lowest class, who, after leaving the hospitals, retained their wretched clothes, and were hence called *lazzaroni*, as being under the protection of St Lazarus.

**LEAD** is a metal very anciently known; it is often mentioned by Moses. Its alchemical name was *Saturnus*. It has a bluish-gray colour, and, when recently cut, a strong metallic lustre; but it soon tarnishes from exposure to the air; specific gravity, 11.358. It is soft, flexible, and inelastic. It is malleable and ductile. In tenacity, it is inferior to all

ductile metals. It soils paper and the fingers, imparts a slight taste, and emits, by friction, a peculiar smell. It is a good conductor of heat, melts at 612° Fahr., and, when cooled, slowly crystallizes in quadrangular pyramids. It is but slowly affected by the atmosphere at common temperatures; but, when maintained in a state of fusion, it absorbs oxygen rapidly, and is converted into a dull-gray dross or powder. When this dross is heated to a low ignition, it becomes of a dull-yellow colour, and is called *common massicot*; and, by a higher heat and longer exposure to the air, it assumes a deeper yellow, and is then called *massicot*. This is the *protoxide of lead*, and consists, in 112 parts, of 104 lead and eight oxygen. It is insoluble in water, melts at ignition, and is unchanged by heat in close vessels. When it contains about four per cent. of carbonic acid, it is called *litharge*. It unites with acids, and is the base of all the salts of the lead. If the protoxide, or metallic lead, be subjected, during forty-eight hours, to the heat of a reverberatory furnace, it passes to the condition of red oxide, or what is commonly called *minium*, or *red lead*. This is regarded by doctor Thomson as a mixture of the protoxide and deutoxide of lead. After the protoxide is separated by acetic acid, the *deutoxide*, of a dark red colour, remains. Its composition is, in 116 parts, 104 lead and 12 oxygen. The *peroxide of lead* is formed by passing chlorine gas through a solution of acetate of lead. Its colour is brown. Heated moderately, especially with the addition of sulphuric acid, it gives out oxygen, and becomes deutoxide, and at a cherry-red heat it passes to the state of the protoxide: 120 parts contain 104 of lead. Lead forms a compound with chlorine, as it is supposed at present, in the ratio of 104 of the former to thirty-six of the latter. The union is effected by exposing the metal in thin plates to the action of chlorine gas, or, more easily, by adding muriatic acid, or a solution of common salt, to the acetate or nitrate of lead dissolved in water. This *chloride* fuses at a temperature below redness, and forms, as it cools, a semi-transparent, horny mass, sometimes called *horn lead*, or *plumbum corneum*. It bears a full red heat in close vessels without subliming. The pigment called *mineral*, or *patent yellow* (also, *fused sub muriate of lead*), is a compound of the chloride and protoxide of lead. It is prepared for the purposes of the arts by the action of moistened sea-salt on litharge, by which means a portion of the protoxide is converted into chloride of lead. It is a paint little used, however, in consequence of the preference given to the chrome yellow. An *iodide of lead* is easily formed by mingling a solution of hydriodic acid, or hydriodate of potassa, with the acetate or nitrate of lead dissolved in water. It is of a rich yellow colour, and is deposited from boiling water on cooling, in crystalline grains of a brilliant lustre. Lead combines with sulphuric phosphorus. The *sulphuret* may be made by simply heating lead and sulphur together, or by the action of sulphureted hydrogen on a salt of lead. It is an abundant natural product, and is known under the name of *galena* in mineralogy. The *phosphuret of lead* is formed by dropping phosphorus into melted lead contained in a crucible, or by heating equal parts of lead filings and phosphoric glass with one-eighth of charcoal powder. It breaks into *laminae*, and is composed of 88 lead, and 12 phosphorus. As respects the *uses* of metallic lead and the oxides, it is well known that the former is much employed in the arts, particularly for buildings and cisterns. For the first of these uses it has many advantages. It is easily worked into any shape, on account of its great softness, and is sufficiently malleable to fold two edges over each

other, so as to make it water tight, without soldering. This is a very great advantage; since, when pieces are soldered together, the expansion and contraction, by a change of temperature, soon cause a rupture. Although it is in very general use for water cisterns, pumps, and pipes for conveying water, serious objections have, from time to time, been urged against its employment for this purpose. Doctor Christison has found that, in pure water, it is oxidised with considerable rapidity, carbonate of lead being formed by the action of the oxygen and carbonic acid of the air. But if the water, as is the case with the majority of springs, contains a small proportion of saline matter, especially if a sulphate be present, which never fails to precipitate lead from any of its solutions, the liability of the water to be prejudiced by the lead is very small. And in other cases, there can be no danger in delivering water through aqueducts of lead, provided they are constantly kept full of water, so as always to exclude the air. Great mischief has been produced by the use of lead in dairies. If the milk runs into the slightest acidity, some lead will be dissolved, and injurious consequences will follow if it is taken into the stomach. In the granulation of lead for shot, a small portion of arsenic is added. The proportion is about two per cent. of the white or yellow arsenic. The compound is heated red-hot for three hours in an iron pot, protected by a tight cover, when the contents are let fall into a reservoir of water, from a height of ten to 150 feet, as the shot are to be coarser or finer. One part of tin and two of lead form an alloy fusible at 350° Fahr., which is used by tinmen under the name of *soft solder*. Lead also forms an imperfect alloy with copper. The metal used for common brass-cocks is an alloy of these two metals. The union of these two metals, however, is exceedingly slight; for, upon exposing the alloy to a heat no greater than that in which lead melts, the lead almost entirely runs off of itself. This process is called *eliquation*. Of the *oxides*, the mixture of the protoxide and deutoxide, which forms the red-lead, is of considerable importance as a pigment. Its manufacture in Germany is conducted as follows: 180 pounds of lead are calcined for eight hours upon the hearth of a cupola furnace, and, being constantly stirred, it is then left in the furnace for sixteen hours, and only stirred at intervals. This calcined lead, or massicot, is ground in a mill with water, washed on tables, and, being dried, is put into stone pots, of such a size, that thirty-two pounds fill them somewhat more than one quarter full. Several of these pots are laid horizontally in the colour furnace, so that the flame may go quite round them, and a piece of brick is put before the opening of each pot. A fire is kept up in this furnace for about forty-eight hours, and the matter in the pots stirred every half hour. The process being over, the red-lead is passed through a sieve. In this operation, 100 pounds of lead generally increase ten pounds in weight. Red-lead is also made from litharge, by heating it in pots in a reverberatory furnace. The *salts of lead* have the protoxide, as has before been remarked, for their base, and are readily distinguished by the following general characters:—1. The salts which dissolve in water usually give colourless solutions, which have an astringent, sweetish taste; 2. placed on charcoal, they all yield, by the blow-pipe, a button of lead; 3. ferroproussiate of potash occasions in their solutions a white precipitate; 4. sulphureted hydrogen and hydrosulphurets produce a black precipitate; 5. a plate of zinc a white precipitate, or metallic leaf. Most of the acids attack lead. The sulphuric does not act upon it, unless it be concentrated and boiling. Sulphurous acid gas escapes during this

process, and the acid is decomposed. When the distillation is carried on to dryness, a saline white mass is produced, a small portion of which is soluble in water, and is the *sulphate of lead*; it affords crystals. The residue of the white mass is an insoluble sulphate of lead. It consists of 5 acid and 14 protoxide of lead. Nitric acid acts strongly on lead. The *nitrate* solution yields by evaporation tetrahedral crystals, which are white, opaque, and of a specific gravity of 4. They consist of 6.75 acid, and 14 protoxide. A *subnitrate* may be formed by boiling in water equal weights of the nitrate and protoxide; also by boiling a solution of 10 parts of the nitrate on 7.8 of metallic lead. Acetic acid dissolves lead and its oxides; though probably the access of air may be necessary to the solution of the metal itself by this acid. *White lead*, or *ceruse* (see *Ceruse*), is made by rolling leaden plates spirally up, so as to leave the space of about an inch between each coil, and placing them vertically in earthen pots, at the bottom of which is some good vinegar. The pots are covered, and exposed for a length of time to a gentle heat in a sand-bath, or by bedding them in dung. The vapour of the vinegar, assisted by the tendency of the lead to combine with the oxygen which is present, corrodes the lead, and converts the external portion into a white substance, which comes off in flakes when the lead is uncoiled. The plates are thus treated repeatedly, until they are corroded through. Ceruse is the only white used in oil paintings. Commonly, it is adulterated with a mixture of chalk in the shops. It may be dissolved without difficulty in the acetic acid, and affords a crystallisable salt, called *sugar of lead*, from its sweet taste. This, like all the preparations of lead, is a deadly poison. The common sugar of lead is an acetate; and *Goulard's extract*, made by boiling litharge in vinegar, a *subacetate*. The power of this salt, as a coagulator of mucus, is superior to that of the other. If a plate of zinc be suspended, by a thread, in a solution of acetate of lead, the lead will be revived, and form an *arbor Saturni*. The acetate, or sugar of lead, is usually crystallized in needles, which have a silky appearance. They are flat, four-sided prisms, with dihedral summits; specific gravity, 2.345. It is soluble in 34 times its weight of cold water, and in somewhat less of boiling water. Its constituents are 26.96 acid, 58.71 base, and 14.32 water. Acetate and subacetate of lead in solution have been used as external applications to inflamed surfaces, scrofulous sores, and as eyewashes. In some extreme cases of hemorrhage from the lungs and bowels, the former salt has been prescribed, but rarely, and in minute doses, as a corrugant or astringent. The colic of the painters shows the very deleterious operation of this metal when introduced into the system in the minutest quantities at a time. A course of sulphureted hydrogen waters, laxatives, of which sulphur, castor-oil, Epsom salts, or calomel, should be preferred, a mercurial course, the hot sea-bath, and electricity, are the appropriate remedies. Dandelion in wines have occasionally sweetened their acid wines with litharge, or its salts. This nefarious adulteration is at once detected by the use of sulphureted hydrogen water, which will throw down the lead in the state of a dark brown sulphuret. Burgundy wine, and all such as contain tartar, will not hold lead in solution, in consequence of the insolubility of the tartrate. The proper counter-poison for a dangerous dose of sugar of lead is solution of Epsom or Glauber salt, liberally swallowed; either of which medicines instantly converts the poisonous acetate of lead into the inert sulphate. Sugar has been found to neutralise the poisonous action of acetate of lead, and therefore is an excellent antidote to it.

We proceed now to speak of the *ores* of this metal, and the method of their reduction.

1. There exists but a single ore of lead which ever occurs in sufficient quantity by itself to justify its exploration;—that ore is the *Sulphuret*. (See *Galenæ*.) It not unfrequently happens, however, that the veins and beds of this species embrace a variety of other ores of lead dispersed through them, which, being mingled with the sulphuret, materially augment the yield of that ore, and which, therefore, require to be noticed, not merely as objects of natural history, but as of value to the miner, who, from their often unpromising aspect, is liable to overlook them among the refuse matters of the mine. In addition to what has already been said of the sulphuret under the article *Galenæ*, we give here a simple mode of assaying a small portion of this ore. Separate fifty *grammes* of it as perfectly as possible from the engaging rock, or gangue; pulverise it, and, mingling it with 12·5 *grammes* of iron in small pieces (small tacks, for example), introduce the mixture into a Hessian crucible, which, being placed within a second one, is to be exposed to the heat of a wind-furnace, or of an ordinary forge, during fifteen minutes; it is then removed, suffered to cool, and broken: a button of lead occupies the bottom of the crucible, which on being weighed, makes known the richness of the ore.

2. *Carbonate of Lead*, or *White Lead Ore*, so called from its prevailing colour, like all the salts of lead, is perfectly unmetallic in its appearance, and is not unfrequently rejected from among common lead ore, as an earthy mineral. It is both crystallized and massive. The crystals are very oblique four-sided prisms, six-sided prisms variously terminated, acute, double six-sided pyramids, tabular crystals, and twin and macle crystals. They cleave parallel to the sides of a right rhombic prism of  $117^\circ$  and  $63^\circ$ , which is the primitive form of the species. Lustre adamantine; hardness equal to that of calcareous spar; brittle; specific gravity, 6·26. It dissolves with effervescence in muriatic and nitric acids, yields a metallic globule on charcoal before the blow-pipe, and is composed of oxide of lead 82, carbonic acid 16, and water 2. This species often occurs massive, and intermingled with earth and metallic oxides, and is sometimes tarnished and blackened, so as to be with difficulty recognised. It occurs in veins in primitive and secondary countries, accompanying galena and other ores of lead. It is pretty abundant in European countries but has been found very sparingly in the United States.

3. *Sulphate of Lead*. Its principal crystallizations are an oblique four-sided prism, variously bevelled or truncated, and a broad, rectangular, four-sided pyramid. It admits of cleavage parallel to the planes of a right rhombic prism of  $103^\circ 42'$  and  $76^\circ 18'$ , its primitive form; lustre shining, adamantine; fracture conchoidal; translucent; hardness that of calcareous spar; streak white; brittle; specific gravity, 6·3. It decrepitates before the blow-pipe, then melts, and is soon reduced to the metallic state. Its constituents are, oxide of lead 70·5, sulphuric acid 25·75, water 2·25. It occurs not very plentifully, in the Harts, Spain, England, and Scotland.

4. Mr Brooke has described within the few last years, three other varieties of lead ore; one of which consists of 46·9 of carbonate and 53·1 of sulphate of lead; another of 55·8 of sulphate, 32·8 of carbonate of lead, and 11·4 of carbonate of copper; the remaining one of 74·4 sulphate of lead, 18 oxide of copper, and 4·7 of water. These will, doubtless, constitute distinct species.

5. *Chromate of Lead* is of a deep orange-red colour; when pulverized, orange-yellow. It occurs crystal-

lized and massive; cleaves parallel to all the planes of an oblique rhombic prism of about  $93^\circ 30'$  and  $86^\circ 30'$ . The cross fracture is uneven, passing into conchoidal, with a splendid lustre. It is sometimes translucent; brittle; specific gravity, 6. When exposed to the blow-pipe, it crackles and melts into a grayish slag. It consists of oxide of lead 63·93, chromic acid 36·40. It has hitherto been found only in Siberia, where it occurs in a vein traversing gneiss and mica slate in the gold mine of Beresof, and in a sand-stone near the same place.

6. *Molybdate of Lead* occurs crystallized in obtuse octahedrons, variously modified, and in tabular crystals. It cleaves parallel to the sides of a right square prism, its primary form; colour wax or honey-yellow; lustre resinous; translucent; hardness below that of calcareous spar; brittle; fracture uneven, passing into conchoidal; specific gravity, 5·09. Before the blow-pipe, it decrepitates; on charcoal, it fuses into a dark-gray mass, in which globules of reduced lead are visible. It consists of 58·4 oxide of lead 38 molybdic acid, and 2·08 oxide of iron. It occurs principally at Bleiberg in Carinthia, with other ores of lead.

7. *Phosphate of Lead* occurs crystallized in the form of a six-sided prism, generally modified on the edges; and, as it cleaves parallel to the sides of the hexagonal prism, that figure is regarded as its primary form; colour, shades of green and yellow; translucent; lustre resinous; fracture imperfect, conchoidal, uneven; brittle; hardness equal to that of calcareous spar. Besides occurring in distinct crystals, it assumes globular, reniform, botryoidal and fruticose shapes. Before the blow-pipe, it melts by itself upon charcoal, and the bead exhibits, in cooling, crystalline facets. It consists of oxide of lead 78·58, phosphoric acid 19·73. In some varieties of this species, arsenic acid is substituted for phosphoric acid. Phosphate of lead is found accompanying the common ores of lead, though rarely in any considerable quantity. Finely crystallized varieties are found at Příbram in Bohemia, at Huelgoet in Brittany, at Lead-hills in Scotland, and at Cornwall in England. In America it occurs at the lead mine near Freyberg in Maine.

Such are the ores of lead, all of which, with the exception of the chromate, are more or less employed in furnishing the lead of commerce; but the salts, as has been remarked above, in very limited quantity, compared with the sulphuret. As the principal thing in the metallurgic treatment of these ores, is to expel the sulphur, after picking and pulverisation, they are roasted either in the open air, or in reverberatory furnaces. During this operation, the sulphur volatilizes, and the lead, reduced to the metallic state, or to that of an oxide, runs into the basin, or crucible of the furnace, where it is deoxidised by being maintained in contact with ignited charcoal. Thus, by this method, which is that generally adopted, the sulphuret passes at first to the state of an oxide in the reverberatory furnace, afterwards is converted principally into the metallic state, and the remainder is passed into other furnaces, where a renewed heating with charcoal compels it to give up its oxygen, and to assume the condition of perfectly metallic lead. There is another mode of treatment practised in Germany and France to a considerable extent. It consists in presenting to the sulphur of the ore a substance with which it has a more powerful affinity than with the lead; this substance is iron. The workmen commence by melting the ore in a reverberatory furnace of small size, and when the bath is full, they throw in twenty-eight per cent. of old iron. In a little time, the sulphur passes from the lead to the iron, leaving the former metal free, which occupies the bottom of the basin. By this means, the

same quantity of ore is reduced as in the first described process, with the advantage, too, of a considerable saving of time, and with one-half of the labour; but it is attended with the complete loss of the iron, which, in some districts, however, is so cheap as to be of no consideration. Britain produces about half the lead of Europe; the Harts, Austria, Prussia and their dependencies nearly all the remainder. The lead mine of Galena, in Illinois, yielded, in 1829, about 6000 tons of lead.

It is pretty certain that both lead and tin were employed, in extremely remote ages, in the fabrication of arms, and, above all, in the ornamental parts of them. Homer also alludes to the practice of putting leaden balls at the end of fishing-lines. The custom of writing on lead mounts also into very great antiquity. Frontinus and Dio Cassius assure us, that the consul Hirtius, besieged in Modena, wrote upon a leaf of lead, respecting his situation, to Decius Brutus, who replied by the same means. Pausanias speaks of certain books of Hesiod written upon sheets of lead; and, if we may believe Pliny, even public acts were consigned to volumes or leaves of the same material. The poets make frequent allusion to leaden coins. Ficorini, in his *Piombi Antichi*, has collected and represented a vast number of monuments of this kind. Caylus conceived them to be all Roman; and thus, according to that writer, those even which represent Egyptian divinities, or are inscribed with Greek characters, are yet to be referred to the times of the Roman emperors. Statues of lead are very rare.

*Lead*; an instrument for discovering the depth of water. It is composed of a large piece of lead, from seven to eleven pounds in weight, and is attached by means of a strap, to a long line, called the *lead-line*, which is marked at certain distances, to ascertain the fathoms.

*To heave the lead*, is to throw it into the sea in a manner calculated to produce the desired effect.

*Deep-sea lead*; a lead of a larger size, being from twenty-five to thirty pounds weight, and attached to a much longer line than the former, which is called a *hand-lead*.

**LEENA**; an Athenian *hetæra* (q. v.), mistress of Aristogiton. Being privy to the conspiracy of Harmodius and Aristogiton against the Pisistratide, when examined on the subject, she bit off her tongue, that she might not be able to speak. A statue was erected by the side of those of the tyrannicides, in honour of her, representing a lioness without a tongue, by the side of which was an image of Venus, whose priestess she was.

**LEAF**. As it is impossible to give an entirely satisfactory definition of what is meant by the word *plant*, or *animal*, so it has equally defied the exertions of naturalists to give a distinct definition of *leaf*. Leaves are the part of the vegetable world in which vegetable life manifests itself most strongly. Light and air, which so essentially influence the vegetable kingdom, act chiefly on the leaves; and, in relation to the air, leaves have been compared to the animal organs of respiration—to lungs placed externally. They are also organs of nutrition, particularly on the lower surface. The same formation which prevails in the trunk, branches, and roots, has been recognised in leaves, only that what in the former is annular and concentric, in the latter is spread out over an extended plane surface. The spiral vessels and sap vessels, which are observable in the leaf-stalk, are also partly to be traced in the leaf, and form the nerves and veins, which may be considered as the skeleton of the leaf. The spaces between them are filled with a cellular substance, covered by a soft, yet firm cuticle. The cellular substance and the cuticle are different

on the upper and the lower surfaces; and, however various the form of the leaves, much conformity always exists in this respect, and is intimately connected with the life of the plant. The cellular substance is particularly filled with sap, generally of a green colour. The cells of the upper surface are commonly disposed lengthwise; those of the lower surface, breadthwise; both commonly destitute of sap. The pores, which are generally only on the lower surface (except in plants whose leaves lie on the water, or close on the ground), serve to transmit the air to the internal parts of the plant; but in some plants they are not discernible, even in some of the more perfect kinds, particularly if the sap is not green. The leaf changes whatever passes through it into the plant from without, or from the plant; and so essential is the influence of light upon vegetable life, that the gaseous substances given out by plants, in the sun, or in the shade, or by night, are chemically different. Sound and green leaves, in the sun, exhale oxygen and absorb carbonic acid gas; but by night, or in the dark, they give out carbonic acid gas, and absorb oxygen from the air: sickly plants, and those whose leaves are not green, do this in the sun. The green colour, the almost universal hue of plants, is so intimately connected with light, that young plants do not begin to assume this colour until they come into the light. The importance of leaves to plants is shown by the fact that no plant can grow nor form blossoms, nor fruits, if deprived of leaves. When fruit has arrived at a certain degree of maturity, it may, indeed, be ripened more rapidly by depriving the plant of its foliage; but this only proves a diseased state. The fine hairs with which leaves are covered, and which sometimes become bristles, contribute considerably to the exhalation and absorption of air and moisture; so that a plant often owes its nourishment to the atmosphere more than to the ground; and many plants exhale much more aqueous matter than, on the highest estimation, they can receive from the ground. The leaves, moreover, have often an important part in the secretion of oil or other substances. There are whole orders of plants, consisting almost entirely of leaves, as certain mosses, heaths, and others, in which the leaf grows place almost entirely to the stem, so that an intermediate formation between the two is presented, as in the *cactus*, *euphorbia*, *staphis*, &c. In many cases, the leaf proceeds only from the joints of the stem, as in the grasses; and, in this case, it retains much of the nature of the stem. No part of the plant is capable of such an immense variety of forms as the leaf, the description of which would exceed our limits. The leaves form an important characteristic in the subdivision of plants. They are divided into simple and compound, the latter class consisting of those in which several leaves are supported on one footstalk, and their various subdivisions are formed on the stem 1. of the apex; 2. of the base; 3. of the circumference; 4. of the margin; 5. of the surface; 6. on their position; 7. their substance; 8. their situation and position; 9. their insertion; 10. their direction. The *lobe* of a leaf is the segment around the apex.

We will add here some interesting terms of a memoir on the structure of leaves, read quite lately by M. Adolphus Brongniart, before the academy of sciences at Paris. The author states that the leaves of plants that live in the air have a totally different structure from those that are completely submerged, and that this difference in the structure of organs is in direct relation to the two principal functions of leaves—respiration and transpiration. In leaves exposed to the air, the surface of the leaf is covered by an epidermis of uncertain thickness, formed of one or more layers of colourless cells, com-

packed together. This membrane is pierced with the pores usually known by the name of *stomata*. The doubts that have been entertained of the existence of perforations in these stomata, M. Brongniart thinks he has removed, and that it is certain that, in the centre of each stoma, is an opening by which the outer air communicates with the parenchyma. The parenchyma is evidently the seat of respiration; for it is the part that changes colour in exercising this function, which becomes green by the absorption of the carbon of the carbonic acid of the atmosphere, and which is discoloured again, in darkness, by the combination of the carbon of its juices with the oxygen of the air. This parenchyma differs entirely from that of other organs, by the numerous irregular cavities that it contains, which communicate with each other and the outer air by means of the openings of the stomata. It is into these cavities, in the cavernous parenchyma of aerial leaves, that the atmospheric air penetrates, when it is absorbed by the surface of the utricles of the parenchyma, that are distended with the fluids which seem to nourish the plant. According to M. Brongniart, aquatic leaves, if submerged, differ in being completely destitute of epidermis. It is not alone stomata that they want, as has long been known, but the epidermis also. There are none of the cavities that abound in the parenchyma of aerial leaves, but, on the contrary, the cellulæ of the tissue are compactly fastened together, without any interstice, and the air, dissolved in the water, can only act on their outer surface. For this reason, the proportion borne by this surface to the whole mass of the leaf, is unusually great. The leaves, from want of epidermis, dry up quickly when exposed to the air, and can only exist in water, or a very humid atmosphere. Hence the author concludes that the epidermis is destined to protect aerial leaves against too rapid evaporation, and the stomata, or pores, of this epidermis become necessary to maintain a communication between the atmosphere and the parenchyma.

LEAGUE; a measure of length, containing more or fewer geometrical paces, according to the different usages and customs of countries. A sea league contains 3000 geometrical paces, or three English miles. The French league sometimes contains the same measure, and in some parts of France, it consists of 3500 paces. The mean or common league consists of 2400 paces, and the little league of 2000. Twenty common Spanish leagues make a degree, or 69; English statute miles. The German league (*meile*) contains four English geographical miles. The Persian league is also equal to four such miles, pretty near to what Herodotus calls the length of the Persian *parasang*, which contains thirty *stadia*, eight of which make a mile. See *Mile*.

LEAGUE. Those political connexions which have been called *alliances*, since the French language has become the fashionable language of Europe, were denoted, during the prevalence of Spanish and Italian influence, from 1500 to 1650, by the term *league* (from the Spanish word *liga*). To some alliances this term is more distinctly applied. Among these are the league of Cambrai, formed, in 1508, between Louis XII., king of France, the German emperor Maximilian, and Ferdinand of Spain, for the purpose of humbling the republic of Venice, and which was joined, in 1509, by pope Julius II. This league was dissolved in 1510, as many similar ones have been, in consequence of mutual distrust, and was succeeded by the *liga santa*, or holy league, between the pope, Maximilian, Ferdinand, and Venice. The object of this was to compel Louis XII., whose allies had now become his enemies, to renounce his conquests in Italy; which object was

gained. This was the first example of a holy league, which name was derived from the participation of the pope. Thirty years afterwards, a holy league was formed in Germany. For when the principal Protestant princes in Germany united, in 1536, to form the union of Smalkalden, in order to protect their common faith, and withstand the emperor Charles V., the Catholic princes assembled at Nuremberg, in 1538, to take measures for the support of their own faith, and to oppose the designs of the Protestant princes; and, as their league had the protection of the Catholic church for its object, they termed it the *holy league*. A fourth league, also, called the *Catholic*, was formed by Henry, duke of Guise, in 1576, against Henry III. of France. Its ostensible object was the support of the Catholic religion; but the duke of Guise had further views of his own. As Henry III. was without male heirs, the throne, at his death, would pass to the Protestant prince Henry of Navarre; to exclude whom, and to obtain the throne for himself, were the real objects of the duke of Guise. His great popularity seemed to render the accomplishment of his design easy. The example given by Paris in his favour was followed by all the provinces. The league was sanctioned by the pope and the king of Spain. In 1588, the duke of Guise was murdered at Blois, with his brother Louis, the cardinal, at the king's instigation. The league then declared the throne vacant, and named the third brother, Charles, duke of Mayenne, governor-general of the kingdom. Henry III. now sought relief in the camp of his former enemy, Henry of Navarre. He was there assassinated in 1589. The war was then pursued by the league against Henry of Navarre, till it was ended, in 1594, by his uniting himself to the Catholic church; and the next year the league was dissolved.

We find a fifth league, in Germany, in the seventeenth century, also termed *Catholic*. The peace of 1555 had not sufficiently restrained the Protestants, and had taken too much from the Catholics. Both parties regarded each other with distrust. The one was accused of encroachments; the other, of unreasonable pretensions. As Henry IV. of France was ready to support the Protestant princes in any manner, for the purpose of humbling the house of Austria, these princes, excited by the injuries inflicted upon the Protestant town of Donauwerth, assembled in 1608, to form a union for their protection. The Catholic princes now took the same steps as after the union of Smalkalden: their association (1610) was also hastened by the disputes respecting the succession of Juliers-Cleves. The principal German princes laid claim to the possessions of John William, duke of Juliers-Cleves-Berg, &c., who had died in 1609, without heirs. Henry IV. supported the Protestant princes: a league was therefore formed, by the Catholic princes, at Wurtzburg, in 1610, at the head of which was Maximilian, duke of Bavaria. The unexpected death of Henry IV. prevented their coming at once to action; but the union and the league kept up a vigilant opposition to each other till the breaking out of the thirty years' war. The head of the union, Frederic, elector-palatine, became king of Bohemia; and then the two parties took the field. An accommodation was at last effected at Ulm, on the 3d July, 1620, by means of the united French, Spanish, Austrian, and the Bavarian influence, in which the union gave up the Bohemian cause, and, after the imperial arms had become victorious in Bohemia, the union was wholly dissolved in 1621. The designs of the Catholics were so well supported by the duke of Bavaria, and his general Tilly, at the head of the troops of the

league, that nothing but the interference of Gustavus Adolphus saved the Protestant princes.

LEAGUE OF THE PRINCES. See *Confederation of the Princes*.

LEANDER. See *Hero*.

LEASE. A lease is a demise of lands or tenements, or permission to occupy them for life, or a certain number of years, or during the pleasure of the parties making the contract. The party letting the lands or tenements is called the *lessor*; the party to whom they are let, the *lessee*; and the compensation or consideration for the lease, the *rent*. There is a great difference in the habits and usages of different communities, as to the modes of occupying lands, and the usual interest and title of the occupants. A great part of the cultivated territory of Europe is occupied by lessees, and rents constitute an immense proportion of the income of persons living upon profits, as distinguished from those who depend partly or wholly upon the fruits of their own labour; so that, in all economical speculations in Europe, in regard to agriculture and the profits of lands and tenements, as distinguished from other species of property and income, the lands are always spoken of as being occupied by lease-holders; whereas, in America, though the tenements in the large towns are usually occupied by lease, and, in the country, many farms are cultivated by those who have only a temporary interest in the soil, yet a great part of the territory is in the possession and occupancy of the proprietors. The general habit and prejudice is in favour of the occupant possessing the fee, and if his capital is not adequate to an independent and unincumbered ownership, he generally prefers to purchase, though he mortgages the land as security for the purchase-money, rather than to hire. This mode of occupying would seem to excite a much more general disposition towards permanent improvements, since the person making them has not only in view the immediate advantage of the increase of products, but also the remote advantage of the increase of the value of the estate. Where leases prevail, however, it is the policy of the proprietors, as well as tenants, to extend the terms to long periods, and thus to give the parties a joint interest in improvements. The state of agriculture, in many parts of Europe, where the system of leases prevails, shows that this system is not so unfriendly to improvements in cultivation as to prevent agriculture from being brought to great perfection under it. But still, all things else being equal, it is quite evident that the proprietor himself will have the strongest motives to a mode of cultivation which adds to the permanent value and productiveness of the soil. It does not, however, follow, that occupancy and cultivation by proprietors are, on the whole, to be preferred, in all possible states of the arts, population, and wealth of a community. The prevailing occupancy by proprietors has the necessary effect of dividing the territory into small farms; the preference of one system or the other will, therefore, depend partly upon the kind of production carried on; for there is no doubt that some species of cultivation can be conducted more effectually, and so as to yield the greatest aggregate of products, if they are conducted on a large scale. In all kinds of industry, whether agricultural, commercial, or manufacturing, a great saving may be made, and greater results produced by the same labour, by combining the operatives in a large system. This is undoubtedly promoted by the system of leaseholds, since the wealthy are thereby induced to invest their capital in lands, as the safest property, and yielding the most secure income. The result will be, that the territory will be owned and leased in large tracts. This is the reason why the

leasehold system, instead of checking the progress of agriculture, probably, on the whole, contributes to it, notwithstanding the fact that a lessee, though for a long term, has less interest in increasing the permanent productiveness and value of the soil, than the proprietor himself. There is, however, one advantage in the leasehold system, and a corresponding advantage in small proprietaries, as the former creates a population of mere labourers, called *cottagers* in England, and *peasants* in the rest of Europe, who, in general, depend wholly upon their wages for subsistence, and who naturally become very numerous in proportion to the demand for their labour, as they are by their competition for employment, their wages become reduced to the means of a bare subsistence. The labour in which they are employed is the most common and requires the least skill and previous instruction of all the different species, excepting, perhaps, agriculture. The consequence is, the raising a great population, of a rude, uncultivated character, without property, and with very little self-respect or consideration with the rest of the community, and who finally become detached from the rest of the community, and have no avenue of escape from their low condition, so that all generous emulation and enterprise die away from among them. It is true, this class is not usually a restless, turbulent, or dangerous part of the community; and it is common, perhaps, to those who do not happen to fall within it. But those who desire to see human nature only in the condition of existence admitting of moral and intellectual culture, and whose philanthropy makes them wish that the whole population may participate in the general mass of intelligence, knowledge, and accomplishments, as equally as is practicable, will prefer that no such class should exist as a body, for precisely the same reason that they do not wish to see any part of the population reduced to servitude. A division of the territory into small proprietaries, and a consequent infusion, through the mass, of a desire of saving, and of possessing property, and the stimulus afforded to enterprise, opening to every individual, even the lowest, the prospect of the next higher class, excites an independent spirit, an energy and activity, whereby the character of the people is elevated. But whatever may be abstractly most desirable, the condition of the lower members of the community is governed, to a great degree, by the operation of economical laws, the influence of which cannot be controlled by the power to lease will necessarily depend upon the extent of the lessor's estate in the land or tenement to be leased. A proprietor who has only a life interest, can, of course, lease his property only during his life. This is the case with a great part of the estates of Europe, the very object of entailment being other limitations, being to secure the property against alienation, and against incumbrances to the heirs of the heir or successor to the inheritance; so that if the incumbent could not make a lease for a certain time, it would be a great abridgment of the power of the estate to himself, as well as to his heirs. The laws, therefore, provide, that certain parts of estates for life may lease, on certain terms, for a time not exceeding a certain period, as twenty or thirty years. The English common law makes a distinction as to the dignity of leasehold estates, in many cases, does not correspond to their relative value and importance, the manner in which a life-estate, being a freehold, is regarded as of more dignity, than a lease for ever or for years, as a hundred or a thousand. A freehold real estate; whereas a lease is but a chattel interest, though the term may be longer than the longest lease. The laws prescribe certain forms for the conveyance

of real estate, requiring it to be by deed. These regulations extend also to leaseholds, usually requiring that a lease for more than a certain number of years, as three or seven, shall be in writing. A mere oral lease is binding for a shorter period; and when there is no specified period of occupancy, the term is understood to be determined either by the agreement for the payment of rent, as a tenement, held on condition of paying a monthly rent, is understood to be let for the term of a month at a time, or it is determined by the nature of the estate leased, as a farm is in a mere verbal lease, understood to be let for one year, this being the shortest time for which it is supposed the parties would intend to contract. So it is held in England, and probably the same rule is law in the United States, though the decisions in some of the states seem to imply, that the letting is also, in this case, determined by the period of payment of rent. But it can hardly be presumed that the parties could intend that the tenant should plough, and plant, and pay rent, and then quit. Leases usually stipulate that, in case of failure to pay rent, the lessor may enter and expel the tenant. As to notice to quit, if the lease be for a certain time, no notice to quit at its expiration is necessary; but if the tenancy be at will, or by sufferance, it can be determined by either party only at the end of the term for which the contract is construed to run; and the party intending to terminate it at the end of any term, is bound to give previous notice of such intention. The general rule, in this respect, is that of reasonable notice; but what is reasonable is subject to diverse interpretation. Though a lease is terminated, yet the tenant may enter afterwards, to harvest the crops of the fields planted by him before the expiration of his lease. The landlord has one privilege over other creditors of the tenant, in respect to his rent, having a right to distrain chattels on the premises, to enforce and secure payment of it. This remedy exists in Britain. A question has been much discussed, and the subject of frequent adjudications, as to the right of the tenant, at the expiration of his lease, to remove fixtures erected by him on the leased premises. The old doctrine was, that whatever he attached to the land, or freehold became thereby a part of the real estate, and that he had not, accordingly, any right to remove it at the expiration of the term. This doctrine was first relaxed, in England, in favour of trade, as it was expressed, meaning, however, industry in general; and, on this principle, a very liberal construction was put upon the tenant's right to remove, at the end of his term, any erections put up by him, for the purpose of carrying on his business, whatever it might be. For this purpose, however, these fixtures must be such that they may be removed without injury to the estate. Things incorporated with the freehold, as repairs put upon a building, remain a part of the real estate, and the tenant has no right to remove them, as they thus become the property of the landlord, although the tenant may have been under no agreement or obligation to make the improvement.

**LEATHER.** See *Tanning*.

**LEBANON**, or **LIBANUS**, and **ANTILIBANUS**; two parallel ridges of mountains in Syria, bounding Palestine on the north. The highest summit of Lebanon is 9800 feet. The cities Saïda (the ancient Sidon) and Tarabolus (Tripoli in Syria) are situated at its base. In the parts of the mountain near the latter city, there are a few specimens remaining of the cedars of Lebanon, which the Phœnicians used in their naval architecture. (See *Larch*.) Antilibanus, or the northern part of the range, is inhabited by the Mutavells; the southern by the Druses. See *Druses*.

**LEBANON**, Nkw; a post-town of Columbia

county, New York; seven miles W. Pittsfield; twenty-seven S. E. Albany. It is situated on the turnpike, between Pittsfield and Albany. The village has a pleasant, picturesque situation, and is well built. Here is a spring of considerable celebrity, issuing from a high limestone hill, so copiously that the quantity amounts to eighteen barrels in a minute. The water contains some lime in solution, but differs very little from very pure mountain water, except by its remarkable temperature, which is that of 73° Fahr., not varying perceptibly at any season. The spring is kept in constant ebullition by a copious emission of asotic gas. It is useful in salt rheums and various other cutaneous affections. The waters are used without injury for all domestic purposes. On the western side of the mountain, opposite to the spring, two miles and a half distant, is a neat village of Shakers, containing about 500 inhabitants. The houses are on a street about a mile in length, and are painted of an ochre yellow. See *Shakers*.

**LEBRUN**, CHARLES, born at Paris in 1618, first painter to the king, was the son of a statuary of ordinary talent. As early as his third year, he sketched with coal, and, at twelve years old, painted a portrait of his grandfather, which is not considered the worst of his paintings. He studied with Vouet, and soon surpassed not only all his fellow pupils, but also his master. After his return from Rome, where, under Poussin, he had studied principally the works of Raphael, and the remains of ancient art, he received the order of St Michael, and in 1648, was made president of the new royal academy of painting and sculpture. He was also named prince of the academy of St Luke, in Rome. From 1661, he was principally employed in embellishing the residences of Louis XIV. and his nobles with works of art, and in superintending the brilliant spectacles of the court. He embellished Versailles, in particular, and was also director of the royal Gobelins (q. v.) manufactory. With the death of Colbert, his influence declined. He died in 1690. Lebrun possessed a comprehensive genius, which was cultivated by the incessant study of history and national customs. Few painters have so well understood the human character, and the expression of the passions. This appears from his treatises *Sur la Physionomie*, and *Sur les Caractères des Passions*. In invention, he equalled the greatest artists who had preceded him. He combined a correct judgment with a lively imagination and facility in execution. He aimed at the highest accuracy of detail, consulting the remains of antiquity, books, and learned men, on the minutest subjects. His weak point in painting was his colouring, particularly of flesh.

**LEBRUN**, PONCE DENIS ECOUARD, a celebrated poet, who, during his life, received the appellation of the *French Pindar*, was born in 1729, and became secretary to the prince of Conti. At the age of twenty-six, he had taken his place in the first rank of lyric poets. At the revolution, he celebrated the birth of freedom in odes and epigrams; but, as the prospect darkened, he changed his tone, and, in 1793, deplored, in harmonious verses, the fate of his country, oppressed by tyrants and anarchists. When the academical establishments were reorganized, Lebrun became a member of the institute. He received from Bonaparte, when consul, a pension of 6000 francs. He died September 2, 1807.

**LEBRUN**, CHARLES FRANÇOIS, duke of Placentia, descended from an humble family in the vicinity of Coutances, came, at an early age, to Paris, where he obtained the protection of M. de Maupeou, whose secretary he became, after having been tutor to his children. He is said to have composed, in 1770, the speech which that gentleman delivered during his

dispute with the parliaments. Being nominated deputy to the states-general (1789), he occupied himself, during the session with affairs of police, finance, and domestic administration. When the question of the church property was discussed, he maintained that it would be an act of injustice to divest the ecclesiastical bodies of their possessions, though he admitted that some reform was necessary and expedient. In Aug. 1790, he voted for the preservation of the French academy, and, in Sept., he appeared at the tribune, to deliver an opinion against the emission of assignats, but he could not procure a hearing. In 1795, he was elected to the council of elders, and became secretary to that body in Jan., 1796, and president in the Feb. following. In Nov., 1799, he approved of the new system of government, and was appointed third consul in Dec. In 1803, the third class of the institute, of which he had continued to be a member from its first formation, chose him their president. He was nominated arch-treasurer of the empire in 1804, and, in 1805, governor-general of Liguria, and created duke of Placentia. On the retreat of Louis Bonaparte from the throne of Holland, Napoleon confided to M. Lebrun, under the title of *governor-general*, the administration of that country, from which the events of 1813 obliged him to retire. On his return to France, he signed the constitution that recalled the house of Bourbon to the throne, and was sent to Caen in the quality of commissioner extraordinary. On the 4th of June following, he was created a peer of France by the king, and, in the beginning of July, was appointed president of the first bureau of the chamber of peers. After the return of Napoleon, he accepted the peerage from him, and likewise the place of grand-master of the university. By this proceeding M. Lebrun rendered himself incapable of sitting in the new chamber of peers, formed in Aug. 1815. In the early part of his life, he published, in prose, a translation of Tasso's *Jerusalem*, more remarkable for its elegance than its fidelity. A new edition of this work appeared in 1805, with an account of the life of Tasso, by Suard (two vols. 8vo). He also made a prose translation of Homer's *Iliad* (three vols., 8vo), which has frequently been reprinted. He died in 1824.

**LECH**; a river rising in the Vorarlberg, and emptying into the Danube. It gives its name to the Lechfeld, a plain in Bavaria rendered famous by the defeat of the Huns (q. v.), by Otho I. in 955.

**LECTOR** (*reader*), in the early church; a servant of the church, whose business it was to read parts of the Bible, and other writings of a religious character, to the people. They were consecrated by prayers and ceremonies for this office, and, when their office became extinct, the consecration still remained; so that the lectorship now forms one of the inferior orders. Lectors are mentioned by Justin Martyr, in the second century, and appear to have been proper officers of the church in the third century. In Germany, a teacher of modern languages in a university is called *lector*, if he is not a professor.

**LEDA**, according to some authors, the daughter of Thestius, a king of Ætolia, according to others, of Glaucus and Laophonte, or Leucippe, was the wife of the Spartan king Tyndarus. In order to enjoy her, Jupiter changed himself into a swan, or, as some say, into a goose, in which form he is represented with her in a picture from Herculaneum. By him she had Pollux and Helen, and by Tyndarus Castor. According to other authors, Jupiter first changed her into a goose, and afterwards himself into a swan, which was the reason why Leda brought forth an egg, from which Pollux and Helen sprang. Other traditions say that Jupiter changed himself into a swan, and caused Venus to pursue him in the form of an

eagle, when he took refuge in Leda's bosom. During a deep sleep, which fell upon her at this moment, he gratified his desire. Others relate that Nemesis changed herself into a goose to escape the pursuit of Jupiter. She then brought forth an egg, which he caused to be carried by Mercury to Leda, who carefully preserved it until Helen was produced therefrom. Again it is said that Leda brought forth two eggs, one by Jupiter, and another by Tyndarus. From the former sprang Pollux and Helen; from the latter, Castor and Clytemnestra. Of these different accounts, that has obtained the preference, which makes Leda, after having had communication with Jupiter in the form of a swan, to have given birth to Castor and Pollux (Dioscuri).

**LEDGER LINES**; those lines, in music, which are added above or beneath the five composing the staff, for the reception of such notes as are too high or too low to be placed upon or within it.

**LEDYARD, JOHN**, a celebrated traveller, was born at Groton, in Connecticut, in 1751. He lost his father at an early age, and his mother was left with but scanty means for the education of four children. To her he was indebted for counsels that made an indelible and most salutary impression on his heart. At the age of nineteen, he went to Dartmouth college, in order to qualify himself to become a missionary among the Indians. At the college, he acquired knowledge with ease, manifested more industry than diligence, and had not been there quite four months when he suddenly disappeared without the knowledge of any one. He is understood to have wandered to the borders of Canada, and among the Six Nations, with whose language and manners he formed an acquaintance, which was afterwards of much service to him in his intercourse with savages in various parts of the globe. Nearly four months elapsed before he returned to his college, and, soon after, in consequence of some reproof for breach of discipline, he resolved to escape altogether. On the margin of the Connecticut river, he felled a large tree, and fashioned its trunk into a canoe, in which he proceeded down the river to Hartford, a distance of 140 miles, much of his course lying through a wilderness, and, in several places, being obstructed by dangerous falls. Ledyard then applied himself to the study of divinity, but, failing in obtaining a license to preach, he turned sailor. His first voyage was to Gibraltar, where, being struck with a military parade, he enlisted, "thinking the profession of a soldier well suited to a man of honour and enterprise." The British commanding officer released his new recruit, who, at the expiration of a year, went back to New London, but soon afterwards embarked for England, in the hope of obtaining assistance from some wealthy relations there. After working his passage as a sailor, to Plymouth, he remained destitute of money, and reached London by begging on the road. He presented himself at the house of a Ledyard, as an American cousin, but was so coldly received, that his dreams vanished, and his pride prevented him from ever renewing the attempt. Captain Cook was then preparing for his third and last voyage round the world. The idea of accompanying him struck Ledyard with so much force, that he at once enlisted in the British marine service, and soon contrived to gain an introduction to captain Cook. "His manner," in the words of Mr Sparks, "mild, but animated and expressive eye, perfect self-possession, a boldness not obtrusive, but showing a consciousness of his proper dignity, an independent spirit, and a glow of enthusiasm giving life to his conversation and his whole deportment—these were traits which could not escape so discriminating an eye as that of Cook. They formed a rare combination, peculiarly suited

to the hardships and perils of his daring enterprise. They gained the confidence of the great navigator, who immediately took him into his service, and promoted him to be a corporal of marines." He embarked accordingly, and performed the whole voyage, of which he published an interesting account some time afterwards at Hartford, in Connecticut. In this volume, he ascribes the murder of captain Cook, in a great degree, to his rashness and injustice towards the natives of Owhyhee. For two years after the return of the expedition to England, Ledyard remained in the British navy; but nothing further is known of him, in that situation, than that he refused to serve against his country. In 1782, he made his way home, and took lodgings at Southold, with his mother, who kept a boarding house, and by whom he was not recognised, after an absence of eight years. We find him soon afterwards at L'Orient, whither he had gone in order to carry into effect his plan of a voyage to the Pacific ocean. At L'Orient, the principal merchants of the place actually furnished him a vessel of 500 tons; but when he was on the point of setting out, the voyage was entirely abandoned by its patrons, in consequence of some misunderstanding with the government. He then went to Paris, where he concerted a scheme with the famous Paul Jones for accomplishing his object, which was also frustrated, and, after making other anxious and fruitless efforts, he gave up altogether the idea of reaching the North-west Coast by sea, and applied to the empress Catharine of Russia, through the medium of Mr Jefferson, then American minister in Paris, for permission to pass through her dominions, having come to the resolution of travelling by land through the northern regions of Europe and Asia, crossing over Behring's straits to the American continent, and pursuing his route down the coast, and to the interior. After waiting, however, for an answer from the empress for more than five months, he accepted an invitation from London to embark in a British ship, which was in readiness to sail for the Pacific ocean, and of which the owners undertook to have him set ashore on the North-west coast. After forming his plan, which was warmly entered into by Sir Joseph Banks and other distinguished men of science, and which was to land at Nootka sound, thence strike directly into the interior, and pursue his course to Virginia, he embarked with no other equipment than a dog, an Indian pipe, and a hatchet. He now thought himself secure of his object; but the vessel was not out of sight of land before it was brought back by an order from the government, and the voyage was finally relinquished. Bearing up with wonderful fortitude against these reverses, he next determined to make the tour of the globe, from London east, on foot, and proceeded to St Petersburg for the prosecution of this design, through the most frequented parts of Finland. In that city his letters procured him eminent acquaintances, among whom Professor Pallas and count de Ségur proved his chief patrons. After waiting there nearly three months, he obtained his passport for the prosecution of his journey to Siberia. On his arrival at Yakutsk, he was prevented, by the Russian commandant at that place, from proceeding any further; and at Yakutsk, whither he had returned, he was arrested as a French spy, by an order from the empress, hurried to a *kibitka* with two guards, conducted with all speed to Moscow, and thence to the frontiers of Poland, where he was released, with an intimation, that if he returned again to the dominions of the empress, he should be hanged. After an absence of seven months, he once more appeared in the British metropolis, to use his own words, "disappointed, aged, penniless, but with a whole heart." He was

now thirty-seven years of age. Scarcely had he taken lodgings in London, when Sir Joseph Banks proposed to him, on behalf of the African association, an expedition into the interior of Africa. He accordingly sought an immediate interview with the secretary of the association, to whom Sir Joseph gave him a letter; and, on being asked by him when he would set out, he answered, *To-morrow morning*. The route traced for him, by the association, was, from Alexandria to Grand Cairo, from Cairo to Sennaar, and thence westward, in the latitude and supposed direction of the Niger. He reached Cairo, whence he was on the point of proceeding on his journey after three months of vexatious delay, when exposure to the heat of the sun, and to other deleterious influences of the climate, at the most unfavourable season of the year, brought on a bilious attack, which proved fatal towards the end of November, 1788. Zeal, activity, courage, honour and intelligence distinguished his short but remarkable career. See Sparks's *Life of Ledyard*, Cambridge, New England, 1828.

LEE; an epithet to distinguish that half of the horizon to which the wind is directed from the other part whence it arises, which latter is called *windward*.

LEE, ANN. See *Shakers*.

LEE, ARTHUR, a distinguished American revolutionary patriot, was born in Westmoreland county, Virginia, December 20, 1740. He was the youngest of five brothers, all of whom became eminent. He was sent to the school at Eton, in England, and upon the completion of his course there, entered the university of Edinburgh, where he commenced the study of medicine, and took his degree of M. D. with great distinction, winning a medal for the best botanical treatise, which was published by order of the university. Having travelled through Holland, Germany, Italy, and France, doctor Lee returned to Virginia, and commenced the practice of his profession at Williamsburgh, then the metropolis. His success was great; but the bent of his mind to politics determined him, before long, to return to England, and study law, in order that he might acquire familiarity with the science of politics and government, and fit himself for taking a part in public affairs, which were then beginning to wear a highly interesting and serious aspect. Before his return, he had heard the parliamentary debate on the stamp act, and when the duty bill was passed, he wrote a series of anonymous papers in relation to it. In 1776, he went again to London, which city he found the stronghold of popular opposition, and the society of the supporters of the bill of rights the most active in conducting it. Of this society he became a member, with the design of connecting the grievances of the two nations, and purchased the freedom of the city, which qualified him to vote in municipal affairs. The complaints of America were introduced into the famous Middlesex petition by Mr Lee, associated with Wilkes; and he also successfully proposed a resolution, that the members of the club would support no candidate for parliament who would not pledge himself to promote the granting of the power of self-taxation to America. The celebrated Junius was an adviser of this body, and with him Mr Lee had an amicable discussion on some points of American policy, about which they happened to differ. His political publications at this period—in which he adopted the signature of *Junius Americanus*—were numerous, and procured for him the acquaintance of Burke, doctor Price, and others of the popular leaders. In 1770, he was admitted to the bar, and began the practice of his new profession, under the most favourable auspices; and such success attended his exertions as to enable him to lay the foundations of an ample fortune. In the same year

the assembly of Massachusetts appointed him their agent, in case of the absence or death of doctor Franklin; and before either of the contingencies occurred, he assisted the venerable sage with his hearty co-operation. As a testimony of the sense of his services, that state subsequently, in 1784, presented him with a tract of land containing 4000 acres. In the spring of 1774, he set out on a tour to France and Italy, and, when at Paris, published an Appeal to the people of Great Britain. Hearing, however, of the dissolution of parliament, before he had completed his journey, he hastily returned from Turin to London. On the return of doctor Franklin to America, in the same year, he became the sole agent of Massachusetts. The secret committee of congress appointed Mr Lee their London correspondent. The principal object of this regulation was, to learn what was to be hoped from the European powers. Mr Lee directed his inquiries particularly to the French ambassador at the British court, through whom he obtained assurances from the count de Vergennes, that his government would secretly furnish to the colonies £200,000 worth of arms and ammunition, to be transported from Holland to the West Indies. He was afterwards appointed by congress one of the commission to the court of France, in conjunction with Silas Deane, to whom doctor Franklin was afterwards added, and continued to labour unceasingly for the cause of his country, by his writings, negotiations, and never-failing vigilance in detecting whatever might prove injurious to its interests. At the same time, he also acted as agent for Virginia, and had the address to procure, under circumstances of special favour, from the royal arsenal, warlike stores to the amount of nearly £260,000. In December, 1777, congress appointed him sole commissioner to Spain, still retaining him on the commission to France. The British ambassador remonstrated against his reception, in consequence of which he was detained at Burgos, on his way to Madrid; but, upon sending a spirited reply to the remonstrance, no further interruption was attempted, and he proceeded to the capital. He there pursued the same policy which he had practised in London and Paris, ingratiating himself and his cause with the men of influence, and appealing boldly and directly to the government, from which he finally procured a large pecuniary loan. Having accomplished all that seemed practicable, he returned to Paris; when, the commissioners having determined on the expediency of conciliating Frederic of Prussia, and prevailing with him to withhold his assistance from Britain, Mr Lee was selected for that duty, and repaired to Berlin, where he was allowed to reside in a private character, and to correspond secretly with the court. He succeeded in obtaining from Frederic an assurance that he would afford no facilities to Great Britain, in procuring additional German auxiliaries, and that he would prohibit the passage, through any part of his dominions, of any troops which that court should thenceforward engage in Germany. He obtained, also, permission for the citizens of the United States to carry on a direct commerce with the subjects of Prussia, and for himself to purchase, for the use of the United States, arms from the armouries from which the king supplied his forces. While in Berlin, his papers were stolen from his chamber; but, upon an order from the king to investigate the affair, they were secretly returned. The blame of this act he cast on the British envoy, who, on the representation of the Prussian monarch, was recalled. When Mr Lee left Berlin, it was with an understanding that a correspondence should be carried on between baron Schulenberg and himself, on the affairs of the United States, and that he should keep the king constantly

informed of the events of the war with Great Britain which he did during his residence in Paris. He was also assured that Prussia "would not be the less power to acknowledge the independence of his country." In forming the commercial treaty with France, Mr Lee objected to two articles, in which it was stipulated that no duties should be charged by the respective governments on any merchandise exported to the French West Indies, which yielded molasses, or on the molasses exported thence to the United States; and, on the suggestion of France, the decision was left to congress, who directed that they should be expunged. Upon the recall of Mr Deane, between whom and Mr Lee there had been some misunderstanding, John Adams was appointed in his place. Their services, however, were soon afterwards superseded by the appointment of doctor Franklin as minister plenipotentiary. During the period of his commission, the speculations of the subordinate agents, who were employed to conduct the commercial details of the public business, had excited the vigilant inspection and unsparing reprehension of Mr Lee. This interference created complaints and insinuations which were artfully disseminated in the United States. These rumours were, in a measure, successful in exciting the suspicions of some members of congress; and when, in 1779, it was determined to send a minister to Spain,—and Mr Lee was certainly a prominent character as to be at once suggested as the fittest candidate,—he was not appointed, although nominated. Upon learning his virtual removal, he resigned his appointments, and returned to America in 1780. He prepared an elaborate report of his official proceedings, and answers to all the charges which had been circulated to his prejudice; but, upon requesting leave to vindicate himself with them in congress, that body expressed their full confidence in his patriotism, asserting that they had no accusations to make, and requested him to communicate his views and information acquired during his residence abroad. In 1781, he was elected to the assembly of Virginia, and by it returned to congress, where he continued to represent the state until 1785. In 1784, he was sent on a delegation to make treaties with the Indians on the northern frontier. He was next called to the board of treasury, with Samuel Osgood and Walter Livingston, in which he continued from 1784 to 1788. Within that period, he also served in a legislative committee to revise the laws of Virginia. On the dissolution of the treasury board, he once then sought the shades of retirement, and established himself on a farm on the Rappahannock, where he died Dec. 12, 1792.—See R. H. Lee's *Life of Arthur Lee* (Boston, 1829), and the review of the same in the *North American Review*; also his letters to Sparks's *Diplomatic Correspondence of the Revolution* (Boston, 1831).

LEE, CHARLES, a major-general in the American revolutionary war, was a native of North Wales, and became an officer at the age of eleven years. He served early in America, where he commanded a company of grenadiers, at the unsuccessful assault of Ticonderoga, by general Abercrombie, and was wounded. He distinguished himself in 1762, under general Burgoyne, in Portugal. He afterwards went on the side of the American colonies, in a contest between them and the ministry, and then entered the Polish service. During his absence, the stamp act passed, and the hostility to it manifested by general Lee rendered him obnoxious to the regents of the court of Vienna. In the course of two or three years, he wandered all over Europe, until a duel with an Italian officer, in which his antagonist was killed, obliged him to flee; and, in 1771, he sailed from London for New York. The queen

between Great Britain and her colonies had now assumed a serious aspect, and Lee formed the resolution to espouse the cause of the latter. Travelling through the colonies, he became acquainted with the most conspicuous friends of colonial emancipation, and, though yet a British officer on half-pay, was active in encouraging the Americans to resistance, and in censuring the measures of the ministry. In 1775, Lee received a commission from congress, and immediately resigned the one he held in the British service; at the same time declaring to the secretary of war his readiness to engage in any honourable service for the king, but reprobating the present measures as inconsistent with the liberty of the subject. In the quality of major-general in the continental service, Lee accompanied general Washington to the camp before Boston. In 1776, he was directed by the commander-in-chief to occupy New York, and to defend that city and the North river against the enemy. On his arrival there, Lee set about strengthening the defences of the city, disarming and securing those who were inimical to the American cause, and checked the intercourse subsisting between the British and the townsmen. He was afterwards invested with the chief command in the southern department. His presence in the south inspired a happy ardour and confidence in soldiers and people, while his conduct on the memorable attack of the British upon Sullivan island raised his military reputation. After the discomfiture of the British at this fortress, Lee passed into Georgia, where he remained some weeks, employing himself in fortifying the colony, and chastising the frontier Indians. Congress anticipating a concentration of the British forces, for the purpose of making a powerful effort at New York, Lee was ordered to Philadelphia, and was despatched to the camp at Fairbairn, with permission to visit the posts in New Jersey. He reached the army just in time to recommend its extrication from a situation, where, had the British used proper diligence in their operations, it would have been completely destroyed. The opinion of Lee induced the council of war to make a precipitate movement during the night, by which they escaped the toils into which they would otherwise have fallen. While marching through the Jerseys to join general Washington, Lee was made prisoner by the British (December 13, 1776), as he was carelessly guarded, at a considerable distance from the main body, and carried to New York. Washington proposed to exchange for him six field officers; but general Howe affected to consider Lee a deserter from the British army, and refused to release him on those terms. Several British officers were confined, and held answerable for the treatment of general Lee. The latter was, however, treated in a manner unworthy of a generous enemy, until the surrender of Burgoyne, October 17, 1787. After that event, he was exchanged. The battle of Monmouth concluded the military course of general Lee. Being directed by general Washington to advance and attack the enemy's rear, he approached very near, but, instead of obeying his instructions, suffered his troops to make a disorderly retreat. The commander-in-chief met him in the flight, and reprimanded him for his conduct. Lee replied in improper language, but executed the subsequent orders of general Washington with courage and ability. Stung to the indignity which he conceived to have been offered him, he wrote two letters to the commander-in-chief, after the action, of a disrespectful nature, challenging him to substantiate the charges implied in his expressions on the field. General Lee was arrested, and arraigned before a court-martial, on disobedience of orders, misbehaviour before the

enemy, and disrespect to the commander-in-chief. August 12, 1778, he was found guilty of the charges, and sentenced to be suspended from any commission in the armies of the United States for the period of one year. The concurrence of congress in this sentence was thought necessary; and, while yet in suspense as to their determination, he published a defence of his conduct. His abuse of general Washington's character, in this pamphlet, led to a duel with colonel Laurens, one of the aids of the commander-in-chief, in which Lee was wounded. Congress confirmed the sentence of the court-martial in his case, though not without previous discussion. Lee retired to an estate he had purchased in Virginia, where he lived, secluded in a small hovel, destitute of glass windows or plastering, amusing himself with his books and dogs. While in this situation, he composed a set of political and military queries, in which his bitter feelings were freely vented, and which were afterwards published in Baltimore, where they created considerable disturbance. In 1782, he went to Philadelphia, where he engaged lodgings in a tavern, and, a few days after his arrival, was seized with a fever, of which he died in obscurity, October 2, 1782. His thoughts would appear to have been employed to the end in the profession which had engaged the best portion of his life, for the last words he was heard to utter were, "Stand by me, my brave grenadiers." From respect to his former services, a large concourse of the people, including many public characters, both French and American, joined in the funeral solemnities.

General Lee was brave in action, of a sound judgment in military affairs, and possessed of the affection of his officers and men. Sensible of his military talents, and insatiably ambitious, he aspired to the chief command, and was little scrupulous about the means to be employed to attain that dignity. Whatever might have been his motives for engaging in the American cause, he sacrificed much for it, and was useful in its advancement. He was a classical scholar, and possessed an excellent memory and a brilliant fancy. His temper was morose and avaricious. His satirical spirit made him many enemies. Though a gentleman in his manners, when he chose to appear such, he was often coarse, and, towards the latter part of his life particularly, became very negligent about his personal appearance. He was very fond of dogs, which he even carried into the company of ladies. With all his faults, however, he was distinguished for sincerity, veracity, and adherence to his friends. He was rather above the middle size. His countenance was not agreeable. Many persons considered him an atheist, though some exalted ideas of a Supreme Being appear in his correspondence. He published some essays on military, political, and literary subjects, which, together with his extensive correspondence, were collected in a volume in 1792. A pamphlet which he wrote on American affairs, in the earlier part of his life, was much approved of by the Americans, and particularly commended by doctor Franklin. It was his earnest desire, expressed in his will, that he should not be buried in any church or churchyard, or within a mile of any Presbyterian or Anabaptist meeting-house; and he assigned as his reason, that since his residence in America, he had kept so much bad company while living, that he wished to avoid it when dead.—See *Memoirs of Charles Lee* (Dublin, 1792); *Anecdotes of Charles Lee* (London, 1797); Girdlestone's *Facts proving Charles Lee to have been Junius* (London, 1813.)

LEE, HENRY, general, a distinguished officer of the American revolution, was born in the colony of Virginia, January 29, 1756, of a highly distinguished

family. He received the rudiments of his education from a private tutor, and was then sent to Princeton college, where he was graduated in the eighteenth year of his age. In 1774, soon after his return home, he was intrusted with the management of all the private concerns of his father, whilst the latter was engaged in negotiating a treaty with some Indian tribes on behalf of the colony, and, in the execution of this charge, he displayed a degree of prudence, industry, and ability beyond his years. In 1776, he was appointed a captain of one of the six companies of cavalry, raised by Virginia, after she had thrown off the authority of the mother country. About this time, the large armies sent by Great Britain into America rendered it indispensable that every possible reinforcement should be sent to general Washington, and, in consequence, those companies were incorporated into one regiment, under the command of lieutenant-colonel Bland, and offered by Virginia to congress. Their services were accepted, and, in September, 1777, they joined the main army of the provincials. Young Lee was thus afforded an opportunity of winning distinction, which he quickly did. He maintained a strict system of discipline, and was extremely careful of his men and horses, by which he was enabled to move with celerity, and strike the enemy by surprise, with certainty and success. He particularly attracted the notice of Washington, who, at the battle of Germantown, selected him, with his company, to attend as his body-guard. In January, 1778, the British formed a plan to capture him. Two hundred of their cavalry succeeded in approaching his quarters, a stone house, unperceived, at a time when his troops were dispersed in search of forage. There were only ten men with him, most of them officers; but, with these, he defended the house obstinately, and the assailants were constrained to retreat. In consequence of this and other exploits, he was, shortly afterwards, promoted by congress to the rank of major, with the command of a separate corps of cavalry, consisting of three companies, to which both cavalry and infantry were subsequently added. In 1780 he was sent, with his legion, to the army of the south, under general Greene, having been previously raised to a lieutenant-colonelcy, and continued with it until the end of the war. In the famous retreat of Greene, before Cornwallis, into Virginia, Lee's legion formed the rear-guard of the American army, and repelled every attempt of the enemy to impede its march. After Greene had effected his retreat to a place of safety, he sent Lee and colonel Pickens into North Carolina, to watch and interrupt the movements of Cornwallis, intending to return himself into that state, and bring the British general to battle. While the two colonels were marching to surprise Tarleton, Lee fell in with a couple of messengers sent to this British officer from colonel Pyle, the commander of a body of 400 American royalists. The messengers mistook Lee for Tarleton, as the accoutrements of his troops were similar to those of the British officer, and communicated to him full information concerning Pyle's movements. Availing himself of the mistake, Lee personated Tarleton, and sent one of the messengers to Pyle, with directions for him to take post at a certain station, where he and Pickens soon after came up with him and dispersed his force. At the battle of Guilford court-house, which happened soon afterwards, Lee eminently distinguished himself. He was placed with his legion, on the left of the front line of Greene's army, and, although the North Carolina militia, the principal force attached to their position, abandoned them at the very commencement of the action, they yet contrived to keep the enemy at bay, until the order to retreat was given by the

American general. Previous to the battle in the morning, Lee encountered the cavalry of Tarleton, and drove them back with considerable loss. During the interval between this battle and that of Camden, in which Greene was worsted by lord Rawdon, Lee took several forts. After the latter engagement, he was sent to aid Pickens in the capture of Augusta, in Georgia, and, in his way thither, surprised and took fort Godolphin, in which there was a valuable deposit of the enemy's military stores. On his junction with Pickens, they immediately invested fort Cornwallis, on which the fate of Augusta depended, and soon forced it to surrender. Its commander was colonel Brown, who was particularly obnoxious to the Americans; and his life would have been a sacrifice to their hatred, had it not been for the precautions of colonel Lee. He then returned, with his prisoners, to the army of Greene, who was, at that time, besieging the fortress of Ninety-six. In that siege Lee had a conspicuous share, and, in the attempt made to take the place by storm, he was charged with the attack in one quarter. He was completely successful; but, the other assault having been less fortunate, the siege was raised. In the action which, a short time subsequently, occurred at Eutaw springs, Lee was also conspicuous, acting at the head of his infantry. By opportunely dismounting his cavalry, he greatly contributed to the enemy's defeat. In the ensuing month of October, he was sent by Greene on a special mission to the commander-in-chief, then employed in the siege of Yorktown, for the purpose of requesting him to prevail on the count de Grasse to afford naval assistance, to enable Greene to lay siege to and take Charleston, with the British army, in the south. He arrived at Yorktown about the time of the surrender of Cornwallis, and, after executing his commission, returned to Greene. Near the end of the war, he married. In the fall of 1786, he was appointed a delegate to congress from the state of Virginia, in which office he remained until the present constitution of the United States was carried into operation. In the interim, he was elected a member of the convention of Virginia, which met in June, 1788, and ratified that constitution, of which instrument he was a strenuous and eloquent advocate. He was afterwards chosen a member of the house of delegates of his native state. In 1792, he retired from his seat in the assembly, on being raised to the chair of governor, which he filled for three successive years. In the last of them he was named by president Washington to command the forces which he was constrained to send into the western counties of Pennsylvania, in order to quell the disturbances by which they were agitated. He performed this duty in the most satisfactory manner. In 1799, he was again chosen a member of congress, and, while there, in the same year, he was selected to pronounce a funeral eulogium upon Washington. He resumed his seat until the accession of Mr. Jefferson to the chief magistracy of the Union, when he resumed his private life, after which he never held any conspicuous office. The latter years of his life were distressed by pecuniary embarrassments, occasioned, to a measure, by his generous hospitality. It was while he was confined, in 1809, within the bounds of Spotsylvania county, on account of pecuniary obligations, that he prepared for publication his excellent memoirs of the southern campaign, in which he took so conspicuous a part—a work which, if not remarkable for great polish of style, is entitled, from its bold, manly, and sincere tone, as well as the power of the descriptions, and the interest of the information, to rank with the best works relating to the revolutionary war.—General Lee happened to be a

Baltimore, in 1814, when the printing-office of an obnoxious paper was threatened by the populace. He was induced, by personal friendship, to take part in the defence of the house. In the dreadful attack which was made on the Baltimore jail, to which the party of defenders were carried for safety, he was severely wounded. His health decayed in consequence, and he repaired to the West Indies, hoping to stop the ravages of disease. In 1818, he returned, to the United States, and died March twenty-fifth of that year, on Cumberland island, near St Mary's, Georgia.

LEE, NATHANIEL, a dramatic poet, was educated at Cambridge, whither he went in 1668, and afterwards went to London, misled, it is said, by the promises of Villiers, duke of Buckingham. Neglected by his patron, he turned his attention to the drama, and, in 1675, produced his tragedy of Nero, and, from that time to 1681, produced a tragedy yearly. He also tried his abilities as an actor, but failed in the attempt. In 1684, insanity rendered his confinement necessary, and he was taken into Bethlehem hospital, where he remained until 1688, when he was discharged, and wrote two more tragedies, the *Princess of Cleves*, and the *Massacre of Paris*, which appeared in 1689 and 1690. He died in 1691 or 1692, in consequence of some injury received in a drunken night frolic. He is the author of eleven plays, all of which were acted with applause; but his natural fire and pathos were buried in a torrent of words, and clouded by a tendency to turgid and bombastic eloquence.

LEE, RICHARD HENRY, a signer of the American Declaration of Independence, was born January 20, 1732, at Stratford, Westmoreland county, Virginia, and, after a course of private tuition in his father's house, was sent to the academy of Wakefield, in Yorkshire, England, where he became distinguished for his proficiency in the classics. He returned to his native country when about in his nineteenth year, and his fortune rendering it unnecessary for him to devote himself to any profession, his time was most usefully spent in the improvement of his mind. The first endeavour which he made to serve his country, was in the capacity of captain of the volunteer companies which were raised in 1755, for the purpose of aiding the expedition under General Braddock. He was disappointed, however, in his patriotic desires, Braddock having refused to accept any more assistance from the provincials than he was obliged to. In his twenty-fifth year, Lee was appointed a justice of the peace for his native county—an office then given only to persons of the highest character, and generally but to persons of considerable experience. Not long afterwards, he was chosen a delegate to the house of burgesses, from Westmoreland county, and thus commenced the career of politics, for which he was peculiarly fitted, both by his natural disposition and talents, and the studies in which he was reared. Works of civil and political morality, history, the principles of the civil law, and the laws of his own country, had occupied the principal share of his time, whilst he had not neglected the more elegant departments of polite literature; and he soon obtained distinction in debate. His voice was always raised in support of those principles which were advocated by the republican or anti-aristocratic action of the legislature; and, when, in 1764, the declaratory act was passed in the British parliament, in pursuance of the right claimed by that body of taxing America, he was the first to bring forward to be subject to the notice of the assembly of which he was a member. A special committee having, in consequence, been appointed to draught an address to the king, a memorial to the house of lords, and a remon-

strance to the house of commons, Mr Lee was placed on it, and selected to prepare the two first papers. These, accordingly, proceeded from his pen, and, in the words of his biographer and grandson, "contain the genuine principles of the revolution, and abound in the firm and eloquent sentiments of freemen." In 1765, Patrick Henry introduced in the Virginia legislature his resolutions against the stamp act, which had just been passed by the British parliament. Mr Lee lent Mr Henry's motion his powerful and most zealous assistance. Not long after it had been carried, in spite of the efforts of the influential party, who advocated the measures of the mother country, Mr Lee, amongst other methods which he took to prevent the operations of the stamp act, planned and effected an association "for the purpose of deterring all persons from accepting the office of vender of stamp paper, and for awing into silence and inactivity those who might still be attached to the supremacy of the mother country, and disposed to advocate the right of colony taxation." The association bound themselves to exert every faculty to accomplish the end for which they had united together, "at every hazard, and paying no regard to danger or to death." In consequence of the opposition the stamp act encountered in the colonies, the British ministry were forced to repeal it; but they did so with a reservation of the right of the mother country "to bind the colonies in all cases whatever." In 1767, parliament having passed two acts, one laying a tax on tea, and the other requiring the legislature of the colony "to make provision for quartering a part of the regular army." Mr Lee exerted himself in every way to excite a spirit of hostility to them, perceiving, as he did, their despotic tendency, and feeling, even then, that a struggle for freedom must eventually take place. It would be impossible for us, consistently with our limits, to enter into a minute detail of the unceasing efforts of Mr Lee's patriotism between this period and the assembling of the first congress in Philadelphia; we can only mention that the celebrated plan which was adopted in 1773, by the house of burgesses, for the formation of corresponding committees to be organized by the legislatures of the several colonies, and also that of corresponding clubs or societies, among the "lovers of liberty" throughout the provinces, for the purpose of diffusing among the people a correct knowledge of their rights, of keeping them informed of every attempt to infringe them, and of rousing a spirit of resistance to arbitrary measures,—both originated with him. The same idea had, about the same time, been conceived and proposed by Samuel Adams in Massachusetts—a circumstance which has occasioned a dispute concerning the merit of having given birth to measures which were the forerunners of the general congress. It cannot be doubted, however, that Mr Lee followed only the suggestions of his own mind with regard to the proposal, as, several years before, in 1768, he had requested Mr Dickinson of Pennsylvania, in a letter, to bestow his consideration upon the advantages of plans which he communicated to him of the same purport. In 1774, the first general congress assembled at Philadelphia, and Mr Lee attended it as one of the Virginia delegation. His labours during this session, as throughout his whole congressional career, until his seal and activity were partially arrested by bodily infirmities, were unremitting. Of all the leading committees—those to prepare an address to the king of Britain, to the people of Britain, and to the colonies, and those to state the rights and grievances of the colonies, and to carry into effect the resolution of non-intercourse with Great Britain—he was a member; and from his pen proceeded the memorial

of congress to the people of British America. In the following year, he was unanimously elected, by the people of Westmoreland county, to the assembly of Virginia, by which he was sent to the second congress. At this period, hostilities were in full operation between the two countries, and one of the first acts of the new congress was to invest George Washington with the command of its armies. His commission and instructions were furnished by Mr Lee, as chairman of the committee appointed for that purpose. The other committees on which he served in this session, were those named to prepare munitions of war, to encourage the manufacture of saltpetre and arms, and to devise a plan for the more rapid diffusion of intelligence throughout the colonies. The second address of congress to the people of Great Britain—a composition unsurpassed by any of the state papers of the time—was written by him this session. But the most important of his services, in this second congressional term, was his motion, June 7, 1776, "that these united colonies are, and of right ought to be, free and independent states; that they are absolved from all allegiance to the British crown; and that all political connexion between them and the state of Great Britain is, and ought to be, totally dissolved." His speech on introducing this bold measure, was one of the most brilliant displays of eloquence ever heard on the floor. After a protracted debate, it was determined, June 10, to postpone the consideration of this resolution until the first Monday of the ensuing month of July; but a committee was ordered to be immediately appointed to prepare a declaration of independence. Of this committee he would have been the chairman, according to parliamentary regulations with regard to the original mover of an approved resolution; but he was obliged, on the same day (the 10th), to leave congress, and hasten to Virginia, in consequence of the dangerous illness of some of the members of his family. Mr Jefferson was substituted for him, and drew up the declaration. In August following, Mr Lee returned to his seat in congress, which he continued to occupy until June, 1777, pursuing, with unabated ardour, the path which was to lead to the freedom and happiness of his country. In that month, he solicited leave of absence, and returned to Virginia. This step was taken on account of the delicate state of his health, and also for the purpose of clearing his reputation from certain stains which malice or overheated zeal had thrown upon it, which he effectually did, by demanding an inquiry into the allegations against him, from the assembly of his native state. The result of this inquiry was a most honourable acquittal, accompanied by a vote of thanks to him for the fidelity and zeal of his patriotic services, which the speaker of the house, the venerable George Wythe, in communicating it to him, prefaced by a warm and flattering eulogy. In August, 1778, he was again elected to congress, but was forced, by his declining health, to withdraw, in a great degree, from the arduous labours to which he had hitherto devoted himself. In 1780, he retired from his seat, and declined returning to it until 1784. In the interval, he served in the assembly of Virginia, and, at the head of the militia of his county, protected it from the incursions of the enemy. In 1784, he was chosen president of congress by a unanimous vote, but retired at the end of the year, and, in 1786, was re-elected to the Virginian assembly. In the convention which adopted the present constitution of the United States, Mr Lee joined in the vote of congress which submitted the plan they proposed to conventions of the people of the states. He was, however, hostile to it himself, thinking that

it had too great a tendency to consolidation. When it was adopted, he and Mr Grayson were chosen the first senators from Virginia under it, and, in that capacity, he moved and carried several amendments. In 1792, his health forced him to retire from public life, when he was again honoured by the Virginia legislature with a vote of thanks. He died June 19, 1794.

LEECH (*hirudo*, Lin.); a genus of molluscous animals, which have an oblong body, a mouth surrounded by a lip, and a disk at the posterior extremity, by both of which they can affix themselves to bodies. In the mouth are three small jaws, tongues, or plaits of skin, by which they are enabled to extract the blood of other animals, that forming their principal nourishment. Leeches are hermaphrodites, and some species are viviparous. They occur in ponds and streams, in almost all countries. They derive their principal interest from the use made of them as a medical agent. There are several of the species which are capable of being thus used, though it is commonly supposed that only two sorts are proper. The employment of leeches in France may be judged of from the circumstance, that the hospitals of Paris require an annual supply of several hundred thousands. The American species do not draw as much blood as the British, which is calculated, on an average, to detract one ounce each, whilst the majority of the Americans do not take more than from two to three drachms each. The leech, when forcibly pulled away whilst sucking, is very apt to leave the teeth, or plaits of skin, spoken of above, in the wound, occasioning pain and inflammation of the part; the leech is then rendered incapable of again biting. The most certain method inducing these animals to bite, is to cleanse the skin thoroughly: the leeches should be exposed to the air for a short time previous to their application, as by this means they will bite more freely. If they are voracious, they may be applied to the part by being held lightly in the finger, or they may be placed in a cup which is to be inverted over the part from which the blood is to be drawn. They should not be disturbed whilst sucking, as the patient be exposed to too great warmth, or they will fall off; this they should always be permitted to do of their own accord. They are made to disgorge, by putting them in a weak solution of common salt; and, if they have not been injured, they may be used five or six times. They are taken either by hand or by means of a glass net. In keeping them, great care should be taken to move the water frequently, and not to place too many in the same reservoir, and to remove speedily all that may die. Notwithstanding every precaution that can be taken, they will sometimes perish in great numbers, apparently from an epidemic disease. It appears that, in such cases, the use of charcoal is the preventive: for this purpose, the bottom of the reservoir is to be strewed with small pieces of the substance, kept down by moss. (See Diction. Hist. nat. et med. des Sanguettes; North Am. Med. and Surg. Jour., 1826, &c.) In 1821, France is said to have exported 1,500,000, and in 1823, 33,650,000.

LEEDS; a large trading and manufacturing town of England, in the West Riding of Yorkshire, 110 miles distant from London. It is situated on the Aire, which is navigable from the Humber up to the town, whence the Leeds and Liverpool canal proceeds on the other hand to the west, so that it is equally open to the eastern and western seas. Along the river, the town extends about two miles from east to west. The houses, mostly of brick,

are in general well built, and, in the modern part of the town, which is daily extending, handsome and elegant. In the other parts, the streets are narrow and crooked. Leeds is a place of great antiquity, as it is mentioned by Bede, the ecclesiastical historian; and it is also noticed in Domesday Survey. A castle formerly existed here, which was besieged by king Stephen in 1139; and in this fortress Richard II., after his deposition, in 1399, was confined for a short time. Leland, writing in the reign of Henry VIII., describes Leeds as "A pretty market-town, subsisting chiefly by clothing, reasonably well builded, and as large as Bradford, but not so quick as it." The town received its first charter of incorporation from Charles I. in 1626, when Sir John Savile, afterwards ennobled, was made the first honorary alderman; and in compliment to him, the arms of the town are very appropriately decorated with Lord Savile's supporters, two of the Athenian birds, sacred to Minerva, the goddess of wisdom, and patroness of the arts of spinning and weaving. A second charter was given to the town by Charles II., in 1661, and renewed by James II. in 1684.

Leeds has long been famous not only for the manufacture of woollen cloth in general, but also as a mart for the two varieties of mixed and white broad cloths. The mixed cloths are those which are made with dyed wool, which in the seventeenth century, were exposed for sale on the battlements of the long and wide bridge over the Aire, and afterwards in the open air in the street, called the Briggate. The inconvenience and damage to the cloth, from exposure to the weather, suggested the necessity of a different arrangement; and in 1758 the mixed cloth-hall was erected at the general expense of the merchants and manufacturers. This is a quadrangular edifice, surrounding a large open area, from which it receives the light abundantly, by a great number of lofty windows; it is 128 yards in length, and sixty-six in breadth, divided in the interior into six departments, or covered streets, each including two rows of stands, amounting in number to 1800, held as freehold property by various manufacturers, every stand being marked with the name of the proprietor. This hall is exclusively appropriated to the use of persons who have served regular apprenticeship to the trade or mystery of making coloured cloths. The markets are held on Tuesdays and Saturdays, and only for an hour and a half each day, at which period alone sales can take place. The market-bell rings at six o'clock in the morning in summer, and at seven in winter, when the markets are speedily filled, the benches covered with cloth, and the proprietors respectively take their stands; the bell ceasing, the buyers enter, and proceed with secrecy, silence, and expedition, to bargain for the cloth they may require, and business is thus summarily transacted, often involving an exchange of property to a vast amount. When the use for selling is terminated, the bell again rings, and any merchant staying in the hall after it has ceased, becomes liable to a penalty. The hall is under the management of fifteen trustees, who hold their meetings in an octagonal building, erected near the entrance to this hall. Similar in its plan to the preceding, is the white cloth-hall, which is divided into five streets, each with a double row of stands, amounting in all to twelve hundred and ten. The markets are held here on the same days, but they do not commence till after the conclusion of those at the mixed cloth-hall, and are subject nearly to the same regulations. Besides these principal halls there is also a small hall of more recent erection, in Albion Street, appropriated to the use of such clothiers as are excluded from the others in consequence of not

having served as apprentices to the trade. The manufacturing district whence these halls are supplied, extends about ten miles southwards of Leeds, fifteen miles to the south-west, and eight or ten to the north and west; the mixed cloths being made chiefly in the neighbourhood of the river Aire, and the white cloths in that of the Calder. Large quantities of fancy goods are also made, such as swandowns, toilinetts, kerseymeres, bear-skins, shalloons, stuffs, Scotch camlets, blankets, carpets, pelisse-cloths, and shawls in great variety. Near the town, are potteries, where large quantities of earthenware are made, and exported thence to Scotland, Ireland, Holland, Germany, Russia, the Baltic, and the Mediterranean; here also are establishments for making canvass, sacking, thread, &c.; others for the finer kinds of linen; and in or near Leeds are several cotton-mills, chiefly worked by means of steam-engines. Here are also iron and brass foundries, with establishments for making various kinds of machinery; oil and mustard mills, paper mills, silk-mills, and works for the preparation of oil of vitriol, aquafortis, and other chemical articles. Within the parish, which is thirty miles in circumference, are several productive coal-mines; and there are likewise quarries of argillaceous schist, whence is procured an abundant supply of slates and flagstones for paving.

Leeds has many elegant public structures, among which may be mentioned the theatre, the new court house, and the commercial buildings. It enjoys the benefits of a Literary and Philosophical Society, an institution for the promotion of the fine arts, several public libraries, &c. The population of Leeds, which in 1775 was only 17,117, amounted in 1831 to 123,393.

LEEK (*allium porrum*); a mild kind of onion, much cultivated and highly esteemed in some places for culinary purposes. The stem is rather tall, and the flowers are disposed in large compact balls, which are supported on purple peduncles.

LEEWARD ISLANDS. The terms *Leeward* and *Windward*, applied to the West India islands, were given them from their situation in a voyage from the ports of Spain to Carthage or Porto Bello. The islands, which lie to leeward, extend from Porto Rico to Dominica.

LEEWARD, To, denotes towards that part of the horizon which lies under the lee, or whither the wind blows.

LEFEBVRE, FRANÇOIS JOSEPH, duke of Dantzig, marshal and peer of France, &c., born at Rufack, department of the Upper Rhine, in 1755, and after having served with distinction in the wars of the republic and the empire, died in 1820. He entered the military service in the *gardes Françaises*, and at the revolution was sergeant. Having warmly embraced the new principles, and distinguished himself by his prudence and firmness, his promotion was rapid. In 1794, he was made general of division; and, in the succeeding campaigns, continued to render himself conspicuous by his courage and military skill. He espoused the cause of general Bonaparte, whose designs he was able to forward on the eighteenth Brumaire, as he had, at that time, the command of the seventeenth military division, which included Paris. His services on this occasion were rewarded by the dignities of senator, marshal of the empire, grand cross of the legion of honour. He bore an important part in the victory of Jena, distinguished himself at Eylau, and received the chief command at the siege of Dantzig, at which he gave the most brilliant proofs of genius and humanity. In 1808, he served in Spain; in 1809, again in Germany; and, in the Russian campaign, commanded the imperial guard. After the abdication of the emperor, the king created him peer, and, during the hundred days,

Napoleon included him in his upper chamber. His name was consequently erased after the second restoration; but, in 1819, he was again summoned to take his seat.

LEFEVRE, ROBERT; a portrait painter in Paris; a pupil of Regnault. He produced also historical pieces of great merit, which, with those of David, Girodet, Guérin, and Gérard, belong to the best of the modern French school. Several portraits of Napoleon by Lefevre are among the best. He died in 1831.

LEFORT, FRANCIS JAMES, the celebrated favourite of Peter the Great, was born at Geneva, 1656. His father, a merchant in that place, sent him to Hamburg to become acquainted with commerce; but, having an inclination for a military life, he went secretly to Marseilles, in his fourteenth year, and entered first the French and afterwards the Dutch service, which he left to go to Moscow, by the way of Archangel, in 1675. Here he became secretary to the Danish ambassador; and a fortunate accident gave him an opportunity to gain the favour of the young czar, Peter Alexiowitch, which he retained till his death. In both was the germ of greatness, which was gradually developed. Peter felt that he needed an instructor and assistant; and Lefort possessed talents fitted for both offices. The first great service which he rendered the czar was in a rebellion of the Strelits (1688). Lefort quelled the insurrection, and saved the prince from the danger which threatened his life. This service gained for him the unbounded confidence of the czar, who was now become the absolute master of Russia. Lefort's influence increased daily. He established the military system of Russia, and laid the foundation of her navy, which Peter afterwards carried to such a degree of perfection. When Peter travelled into foreign lands, in 1697, Lefort was the principal of the embassy, in the train of which the czar remained incognito. In the mean time, the nobles, jealous of the favour shown to a foreigner, saw a favourable opportunity to revenge themselves, in the long absence of Lefort and the czar. The Strelits rebelled; but Peter darted on them with the rapidity of an eagle, and took a bloody revenge. The czar, Lefort, and Mensikoff executed the guilty with their own hands. Soon after, Lefort died (1699). He had a comprehensive and cultivated mind, a penetrating judgment, much presence of mind, great dexterity in sounding those of whom he wished to make use, and an uncommon knowledge of the resources of the Russian empire. The groundwork of his character was firmness, invincible courage, and justice; but his habits were irregular, which hastened his death.

LEGATES, with the ancient Romans, were the assistants of a proconsul or proprætor, in the administration of a province and in the command of the army; also the higher officers, who commanded under the general-in-chief of any army. Of the papal legates, there are several kinds. *Legatus natus* is a mere title connected with an episcopal see, by the grant of the pope. These see lie out of the Roman states; among them are those of Treves, Cologne, Salzburg. The real envoys are called *legati missi*. Among them, the *legati a latere* have the highest rank, and are sent on particularly important missions to the principal courts, or into the provinces of the papal dominions as governors. They are taken from the college of cardinals only. The districts of the States of the Church, therefore, are called *legations*. Legates who are not cardinals are called *nuntii apostolici*. If they are sent *cum facultate legati a latere*, their power is equal to that of a *legatus a latere*. All Catholic governments, however, do not allow them equal authority. Thus the Austrian expressly prohibits any clergyman from transacting business with the pope through the legate.

LEGATION is used to signify the body of official persons attached to an embassy; hence *secretary of legation*. (See *Ministers, Foreign*.) *Counsellor of legation* is a title bestowed in Germany—the head of counsellors—on certain officers connected with the ministry for foreign affairs. Very often, however, it is a mere honorary title, conferred upon persons who never had any connexion with politics, as Jean Paul Richter, who was made counsellor of legation by one of the petty princes. *Legation* also signifies a division of the States of the Church. See *Legate*.

LEGATO (*Ital.*); a word used in opposition to *staccato*, and implying that the notes of the movement or passage to which it is affixed are to be performed in a close, smooth, and gliding manner, holding each note till the next is struck.

LEGEND (*legenda*); the title of a book containing the lessons that were to be read daily in the service of the early Roman Catholic church. The term *legend* was afterwards applied to collections of biographies of saints and martyrs, or of remarkable stories relating to them, because they were read at matins, and in the refectories of cloisters, and were earnestly recommended to the perusal of the laity as proofs of the Roman Catholic faith. The Roman breviaries likewise contain histories of the lives of saints and martyrs, which were read on the days of the saints whom they commemorated. They originated in the twelfth or thirteenth century, and they contributed much to the extinction of the old German (heroic) heroic traditions. In the middle ages, a collection of the lives of the saints was known by the name of *Legenda Sanctorum*, or *Historia Lombardica*. There is a celebrated collection, called the *Golden Legend* (*Aurea Legenda*), by Jacobus de Voragine, archbishop of Genoa, who died in the year 1298. The histories of saints, which are founded merely on tradition, are also known by the name of *Legends*. (See *History*.) historical and critical treatise on the histories of the saints and martyrs, in his work entitled *Les Fies des Saints*.) As these histories were often nothing more than pious fictions, the name of a *legend* was given by the incredulous to all fables of a similar nature, to all fictions which make pretensions to truth. Valerius Augustinus, who was bishop of Verona in the sixteenth century, in his work *De Rhetorica Christiana*, ascribes the numerous fables, which have been ushered to the world under the title of legends, in part to the custom prevailing, in many monasteries, of requiring the monks to write Latin paraphrases and dissertations on the most striking circumstances in the lives of the saints, in which they were allowed to ascribe to tyrants and persecuted saints such words and actions as they considered most adapted to their situation and character. This gave rise to those embellishments of history, which were preserved, and afterwards found in monasteries, and mistaken for true histories. Although many of the legends are tasteless and unmeaning fictions, the offspring of childish credulity, or intended to gratify it, there is also a large number of highly poetical and ingenious fables among them. Hence many poets have attempted to avail themselves of these rude materials, and to arrange them in the modern taste; and hence every poetical fiction, in the style of ecclesiastical tradition, whether in verse or prose, is called a *legend*. The principal characteristic of a legend is the marvellous, which should be of a religious nature, or relating to some traditions of the church, without, however, falling into frivolity. The legend is a production of Christianity, and, like the traditions of the church, wholly different from the *mythos*, or ancient fable. The style proper to it is plain and simple, such as would naturally flow from the gentle imagi-

tion of a pious heart, and wholly inconsistent with ornament and poetical decorations.

*Legend* is also used for the motto or words engraved, in a circular manner, round the head or other figure upon a medal or coin. The meaning of this term is similar to that of *inscription*; but the latter refers chiefly to the writing placed in the middle of the coin, while the legend, as we have just observed, surrounds it.

LEGHORN (*Livorno*); a commercial city in Tuscany, on the Mediterranean; lat.  $43^{\circ} 33' 5''$  N.; lon.  $10^{\circ} 16' 53''$  E. The streets are even and well paved, but narrow and dark, from the height of the houses, which are of stone: there are, however, no palaces, like those of the other towns of Italy. The finest street is the *strada Ferdinandea*, which passes through the middle of the town to the port, through the *piazza d'armi*. The town occupies but a small space in proportion to its population, contains seven churches, one archducal palace, one Greek, one Armenian church, and 65,355 inhabitants, amongst whom are about 20,000 Jews in a separate quarter of the town, who possess a beautiful synagogue, two schools, a library, a printing-office, several collections, and many privileges. Greeks, Armenians, and Turks (who have a mosque), are also found here. There are large magazines of salt, tobacco, and oil. In the neighbourhood of the town is an excellent quarantine establishment with three lazarettos. The coral works produce 160,000 dollars yearly. There are also distilleries of rosoglio, tanneries, dyeries, paper, and tobacco manufactories. The port is annually visited by more than 4000 ships. A packet sails between this place and Marseilles. Leghorn is the principal commercial town of Italy, and has an extensive trade to the Levant. The principal commercial nations have consuls at Leghorn. Commerce is principally in the hands of foreigners, particularly the British. The Armenians and Jews are the general brokers of all nations. Much commission business is carried on, and there are large dealings in bills of exchange. The exports of Leghorn consist principally of raw and manufactured silks, olive-oil, fruits, shumac, valonia, wines, rags, brimstone, beeswax, marble, argol, anchovies, manna, juniper berries, hemp, skins, corn, &c. Leghorn plaiting or straw hats is the finest in the world, and large quantities are imported into Britain. The imports are very numerous and valuable comprising all sorts of commodities, with the exception of those produced by Italy. Recently, however, the trade of Leghorn has fallen off. Since 1633, it has been an important commercial place. The town, which was then insignificant, was at that time enlarged. The port is protected by two strong towers situated on rocks in the sea, and by an old castle. It is able to become choked, and has not sufficient depth for large ships; these, therefore, have to anchor outside the mole which protects the harbour. This mole 600 paces in length, is well paved, and used for landing. On the place before the inner port is the colossal marble statue of the grand duke Ferdinand I. From thence a bridge leads to the outer port, where the greater number of vessels are at anchor. Without the port, on a rock in the sea, is a light-house. Good water for drinking is brought from a well, to which little vessels go daily, drawn by men and horses. Between the town and the surrounding suburbs is a long promenade, called *gli Sparti*. The sea, the *piazza d'armi*, the road to Monte Nero, a place of pilgrimage, also serve as public promenades. In 1279, Leghorn was still an open town. When the port of Pisa was destroyed, the prosperity of Leghorn increased, particularly when it passed to the Venetians in 1421 and 1495. Alexander of Medici

made it a strong-hold, and built the citadel. Cosmo I. declared the port a free port. From this time forward, the wealth of Leghorn has increased (interrupted only by the wars of the revolution, and, in 1804, by the yellow fever). The society of arts and sciences there established is called *Accademia Labronica*.

LEGIO FULMINATRIX (*the thundering legion*).

This term was applied to a Roman legion in the time of the emperor Aurelius. The following account of the name is given by the Christian traditions. After the expulsion of the Marcomanni and Quadi from Hungary, the emperor Marcus Aurelius, pursuing these German tribes with a detachment of his forces, A. D. 174, was shut up in a valley, surrounded on every side by high mountains. To those who were thus cut off from the main body of the army, the heat and the want of water were no less dangerous than the attacks of the enemy. In this crisis, a sudden shower of rain reanimated the Roman soldiers. At the same time, a storm of hail, attended with thunder, assailed the enemy, who were now easily repulsed and conquered. Both heathen and Christian authors agree in their relation of the principal circumstances of this event. The adherents of each religion saw in it the influence of the prayers of their brethren. According to Dio Cassius (*Excerpta Xiphilini*, l. lxxi., cap. 8), the miracle was wrought by an Egyptian sorcerer in the train of the emperor; according to Capitolinus (*Vita Marc. Aurel.*, cap. 24), it was the effect of the emperor's prayers; but, according to Tertullian (*Apologet.*, cap. 5, *Ad Scapul.*, cap. 4) and Eusebius (*Hist. Eccles.* l. v., cap. 5), it was brought about by the prayers of the Christians in his army; hence the legion to which these Christians belonged was denominated *fulminatrix*. The letter of the emperor Marcus Aurelius, commonly printed in Greek in the first apology of Justin Martyr, gives the same account with the Christian writers; but it is spurious. The marble pillar erected at Rome in honour of Marcus Aurelius, and still standing, represents this deliverance of the Roman army, the Roman soldiers catching the falling rain, and a warrior praying for its descent. It is not, however, to be considered as a memorial of any influence exercised by the Christians in the event.

LEGION; a division of the Roman army. Under Romulus, it was composed of 1000 foot and 100 horse, selected from each of the three tribes. The body thus selected (hence the name *legio*) amounted, therefore, to 3300 men. In the time of Polybius, a legion consisted of 4200 men, and it was finally increased to 6200 foot. All the soldiers of a legion were Roman citizens: no slaves were admitted, except in cases of the most pressing necessity; nor any citizen under seventeen years old, except in peculiar circumstances of danger. There was commonly an equal number of auxiliaries attached to each legion, so that, in the later periods of Roman history, we must understand by a *legion*, a corps of 9000 or 10,000 men. The foot of each legion, when it consisted of 3000 men, were divided into ten cohorts, and each cohort into three companies (*manipuli*) of 100 each, hence called *centurie*. When the legion was enlarged, the same division was still retained, with the difference that each *manipulus* was now divided into two centuries, and each century into ten *decurias*. The commander of a legion was styled the *legatus*. Sometimes, instead of a legate, six military tribunes were appointed from each, who commanded in succession, each for the space of a month, under the direction of the consul. The principal standard of a legion was a silver eagle; and the legions were named from their commander (as the *Claudian legion*), or from the place

where they were stationed, or from some deity, or from birds, or from some remarkable event. The following cut represents various standards of Roman legions:—

In the time of Augustus, the army consisted of twenty-five legions.

*Legion* is also used, proverbially, to signify a large and indefinite number of persons or things. This term was revived in the time of Napoleon, and has since been commonly applied to a body of troops of an indefinite number, and usually of different kinds. Such legions are mostly formed at the beginning of a war, and dissolved at the close. Of this sort were the English-German legion, and the Russian-German legion, in the last war for the independence of Europe. The French national guards were divided into legions and cohorts. After the dissolution of the army raised by Napoleon in 1815, the remains of which had retired beyond the Loire, the new French army was divided into legions, which were named from the departments. This arrangement, however, was abolished towards the close of the year 1820.

**LEGION OF HONOUR** (*légion d'honneur*); an order instituted by Napoleon, while consul, May 19, 1802, for military and civil merit. The proposition produced much debate in the legislative body, and passed after a strong opposition. It was the object of Napoleon to kindle a spirit of ambition, the most necessary national element for the support of wars, of which he foresaw that it would be necessary for him to wage many, and for this purpose the institution was admirably calculated. At the same time, it cannot be denied that, abstractly considered, it is to be regretted, that a nation, which had just declared itself so loudly for liberty, should appear so eager for ribands—an invention of those very times against which the revolution was directed. Moreau, who was altogether opposed to Napoleon, ridiculed the institution. The cross of the legion of honour was given to all who had previously received a military weapon as a mark of honour, and to a great number of new members. Its effect upon the soldiers was very great. After Napoleon's assumption of the imperial dignity, the statutes received some modifications. The oath was originally as follows: "I swear, on my honour, to devote myself to the service of the republic, to the preservation of the integrity of its territory, to the defence of its government, its laws, and the property by them consecrated; to oppose, by every means which justice, reason and the laws authorize, all acts tending to re-establish the feudal system, or to revive the titles and distinctions belonging to it; finally, to contribute, to the utmost of my power, to the maintenance of liberty and equality." After Napoleon became emperor, the form of the oath was somewhat changed. The members swore to devote themselves to the service of the empire, to

the preservation of the integrity of the French territory, to the defence of the emperor, to the support of the laws, and of the property which they had made sacred; to combat, by all the means which justice, reason and the laws authorized, every attempt to re-establish the feudal régime, and to concur, with all their might, in maintaining liberty and equality. The decoration consisted of a star containing the portrait of Napoleon, surrounded by a wreath of oak and laurel, with the legend *Napoleon, empereur et roi*; on the reverse was the French eagle with a thunderbolt in his talons, and the legend *Honneur et patrie*. The star of the *légionnaires* was of silver, that of the officers of gold, and was suspended from a red riband with a white margin. The order consisted of grand-crosses (*grand aigle*), who wore the cross on a broad riband hanging over the left shoulder, and a star on the left side of the breast; of grand-officers, who wore the cross in the button-hole, and a star, somewhat smaller on the left side; of commanders, who wore the cross round the neck; of officers, who wore the gold cross with a bow in the button-hole, and of legionaries, who wore the silver cross with a simple riband in the button-hole. The legion was composed of sixteen cohorts, each of which had its seat in a different city, and contained 407 members: the whole number was, therefore, at first, 6512. Each cohort had a chancellor, treasurer and chief—the whole order a grand-chancellor and grand-treasurer. The pension of a grand-officer was 3000 francs, annually; of a commander, 2000; of an officer, 1000; of a legionary, 250 francs. There was also an institution for the education of the daughters of members of the legion of honour at Ecouché, under the care of Madame Campan. After the restoration of the Bourbons, the order underwent essential changes. The head of Henry IV. was substituted for that of Napoleon, with the legend *Roi de France et de Navarre*; and, on the reverse, the *fiat de la croix* took the place of the eagle. The grand-crosses were limited to eighty, the grand-officers to 160, the commanders to 400, the officers to 2000: the number of the legionaries was left unlimited. New members received no pensions, whilst those of the old members exceeded the prescribed sum; but on the death of the old members, the new ones were to receive their pensions. Foreign members received no pensions. It was evident that the legion of honour was badly treated by the Bourbons, who restored the old order. The members created during the hundred days were, of course, not acknowledged by the Bourbons; but, in 1831, general Lamarque obtained their acknowledgment by a spirited speech, in the chamber of deputies, for which they sent him a sword with an inscription. Military honours are paid to the members of the legion, as they are also to the bearers of the *croix de Juillet*, which has been granted to 1300 persons who distinguished themselves during the struggle of July, 1830. This cross takes precedence of that of the legion of honour.

**LEGISLATION.** See *Law*.

**LEGISLATIVE BODY** (*corps législatif*): an assembly, in the time of the French consulate and empire, consisting of 300 persons, which had neither the right to discuss nor to initiate a law, but merely to vote on a law proposed by the government and discussed by the tribunate (as long as that body existed) in their presence. The tribunate, on the other hand, had not the right to vote. It was an extremely lame contrivance, showing the political imperfections of the French at that time.

**LEGISLATURE, HOUSE OF.** Whether it is preferable to have two houses of legislature or one, has been a question on which politicians have maintained different opinions, though, at present, public

opinion appears to be in favour of two houses, the instances of Britain and the United States of America, giving great weight to this division of the legislative power, and a single house in the case of large nations seems to be ill adapted to modern representative governments. During the middle ages, indeed, and as long as the assembly of the estates existed, these formed, in general, certainly, only one body; for, although the different estates may have met in different rooms, they had no proper independence of each other. In England, which has led the way in constitutional institutions, a happy conjunction of circumstances early united the clergy with the high nobility into one house, and the lower nobility, or gentry, with the representatives of the cities, into another; whilst, in the countries of the European continent, the clergy, the nobility, and the representatives of the cities, although they constituted different estates (in some cases, the superior nobility [*magnates*] and the free peasants formed also distinct estates), made but one legislative body; and, in most cases, the representation was so unequal, that the nobility and clergy entirely outweighed the commons, threw all the burdens of the state upon the citizens and peasantry, and prevented, almost entirely, the development of constitutional establishments. In England, however, the division into two houses has had the effect of repressing the assumptions of different classes, by making them mutually checks upon each other, developing constitutional and public law, and introducing general taxation, and has contributed most essentially to the superiority in political advantages of the English people over the other nations of Europe. See the article *Britain*, division *Parliament*; in that article, also, will be found an account of the privileges of the two houses, and of the difference between them.

In the more important British colonial establishments, political institutions, modelled, to a considerable degree, on those of the mother country, have been introduced—a governor, with a council (appointed by the British government), and a house, or assembly, with members elected by the people. This is the case where the extent and population of the colony warrants such an organisation, and where the colony does not belong to a company, or where the great number of natives, living interspersed with the colonists, does not prevent such an establishment. Thus a council and a house of assembly exist in the two Canadas, Nova Scotia, New Brunswick, the British West Indies, and they existed in many of the colonies, which afterwards declared themselves the United States of America. The latter established, on declaring themselves independent, a congress, consisting of delegates from the several states, invested with certain powers by the articles of confederation, and forming but one body. After the close of the revolutionary struggle, the federal constitution established a house of representatives, chosen by the people of the several states, and a senate, consisting of members chosen by the legislatures of the several states for six years. The separate states also established each two houses of legislature, with the exception of Vermont, which has but one. In Massachusetts and New Hampshire, the senators are apportioned among districts, with reference to the amount of taxes paid by the districts respectively. In the other states, the rule of apportionment is that of numbers. In the tabular view of all the constitutions of the United States, affixed to the article *Constitution*, the reader will find the term for which, and the conditions upon which, the members of the two houses are elected, in the different states, and for the federal government.

The French revolution began by uniting the three

estates in one house, in 1789. Different constitutions were framed in rapid succession. The constitution of Sept. 3, 1791 (monarchical), established but one legislative house. The constitution of June 24, 1793 (republican), declared, in section thirty-nine, the legislative body “one, indivisible, and permanent.” The constitution of the year III., Sept. 23, 1795 (with a directory of five members), established a council of elders, consisting of 250 members, and a council of five hundred. The members of the latter were to be, at least, thirty-five years of age, those of the former, at least, forty years. The council of five hundred had the exclusive right of initiating laws. Both were chosen for three years. The constitution of Dec. 13, 1799 (consular), established a legislative body, which could only adopt or reject propositions made by the government, and communicated and discussed by the tribunate. (See *Legislative Body*.) The members were chosen for five years. There was also a conservative senate. (See *Senate*.) The consulate for life, and the imperial government, retained the legislative body, but the tribunate was abolished. The *Charte Constitutionnelle* at last established houses of peers (for life or hereditary), and of representatives—the latter on the basis of taxation. See *Charte Constitutionnelle*, *Election*, and *France*.) In the article *France*, it will be seen, that, in 1830, when the elder Bourbon line was declared to have forfeited the throne, it was provided, in the additions to the charter, that the organization of the peerage should undergo a revision in 1831: the result we shall give under the article *Peer*.

Poland, by the constitution granted by the emperor Alexander, had two houses—a senate, consisting of members appointed for life by the sovereign, and not by the viceroy, and a house of representatives. The kingdom of Norway has two chambers—the *Logthing* (q. v.) and the *Odelsting*, both together composing the *Storting*. (q. v.) Bavaria, Hanover, Wurtemberg, Baden, and Hesse-Darmstadt, have each two houses. The constitution which Joseph Napoleon gave to Spain, July 6, 1808, established one house, the cortes, consisting of three estates,—the prelates, nobility and people, with a senate, which, however, is not to be considered as a branch of the legislature. The constitution of the cortes of March 19, 1812, established but one house—the cortes. This organization was imitated in Piedmont, Naples and Portugal, at the time of the respective revolutions in those countries. The constitution granted to Naples by Joseph Napoleon, June 20, 1808, established one house—a national parliament—consisting of five benches (*sedili*), those of prelates, nobility, landholders, learned men and merchants. Lord Bentinck’s constitution for Sicily (1812) established two houses. In Sweden, by the constitution of June 7, 1809, there is but one house, consisting of the estates—the nobility, clergy, citizens, and crown peasants. In the kingdom of the Netherlands, there were two houses of the states-general, one composed of members for life; and, also, two houses of the provincial estates. Saxe-Weimar has but one house, as had Saxe-Hildburghausen, at least before its union with Meiningen. Under the article *Netherlands*, we shall give the new Belgian constitution. In the Ionian Islands, there is a senate of ten members, and a legislative body of forty members. (See *Ionian Islands*.) The diet of Switzerland (*Tagsatzung*) consists of nineteen deputies, who vote according to instructions from their respective cantons. The constitution of the German diet (*Bundestag*) is similar. (See *Germanic Confederation*.) Neither of these bodies has any resemblance to the congress of the United States of America. The constitutions of the new American governments, as Colombia, Brasil, Mexico, &c., have,

in general, established two houses, on the plan of those of the United States. In Bolivia, the legislative department consists of three branches, the tribunes, the senators, and the censors. (See *Brazil, Peru, Mexico, &c.*) We ought to mention, in connexion with this subject, that, in most governments, the executive has also a legislative voice, in so far that its sanction is required to give the force of law to the acts of the legislative bodies. Thus, in Britain and France, the royal assent is necessary to the passage of a bill. In the United States of America, the president, and, in the larger part of the states, the governors, have a provisional *veto*.

LEGITIMACY; from *lex* (the law), whence *legitimus* (conformable to law); hence *legitimate* children are the offspring of a lawful marriage; and those which are born out of wedlock are said to be *legitimated* when they are declared legitimate by the state. A person *legitimizes* his claims when he produces legal proof of their justice. After the French revolution, in the last century, had deprived the Bourbons of the throne of France, to which they laid claim by virtue of their right of succession, and, in particular, after their recovery of it, in 1814, the word *legitimacy* became very common in the language of European politics. The question, Who is the legitimate ruler? is intimately connected with the general subject of sovereignty. (q. v.) Formerly, when political questions were treated less scientifically, legitimacy was not so much a point of contest. States, countries, nations, passed by inheritance, conquest, marriage contracts, &c., and the legitimacy of a prince was decided, generally, like an affair of ordinary diplomacy; less, however, in the case of Britain than of the continent. But when the allies dethroned Napoleon and his brothers, they wanted something to oppose to the claims which he derived from his election by the people. A phantom was therefore created, at the congress of Vienna, called *legitimacy*, and since that time, has been constantly used, but never defined, which, indeed, it cannot be, because the facts before the world are too stubborn for this theory of the hereditary descent of nations, like common property. If this right of inheritance could be proved, legitimacy would be something very easily definable; but there is a difference between an estate and a nation. The Austrian Observer, a semi-official paper, in order to prove the Turks legitimate masters of Greece, once defined legitimacy thus: "Every sovereign is legitimate who is such by a long series of treaties with other lawful sovereigns." Austrian logic! Misconceptions of certain passages of the Old Testament, a confusion of religious and political ideas, together with feudal views surviving the institutions which gave them birth, have involved the question of legitimacy in great obscurity. The most absurd doctrines have been broached in the attempt to support this doctrine of the holy alliance, and other follies, which have been maintained at the expense of the blood and happiness of nations. If it rests on long possession, we might ask how many generations are required to legitimate robbery; or we might say, with Luther, that, on this principle, Satan is the most legitimate of rulers, because his kingdom is the oldest. In our prosaic times, those who rest the right of sovereignty on birth cannot, like the ancients, make a Jupiter or an Apollo the founder of a royal line, and deduce the divine right of princes from their divine descent; and, if they look no higher than a human ancestor, it will be hard to prove the direct descent of many a princely house from the source whence it derives its claims to sovereignty. The memoirs of courts show how often plebeian blood has been mixed with royal. But it is needless to spend time in refuting a theory which even Chateau-

brand, once its staunch defender, has disclaimed. In a late speech, he says, "I do not believe in the divine right of kings," and "monarchy is no longer a religion; it is a political form."

For all who consider the state as a society of men with equal rights, and the government as established for their welfare, the question is easily solved. He who rules with the approbation of the people is legitimate. If, after submitting, for a while, to one family, they choose to transfer their allegiance to another, they have, incontestably, the right to do so. The mistakes to which they may be liable, in using their rights, do not affect the rights themselves. The good of the people is the sole object of government, and no title, however, high-sounding, or old, or well-earned, can contest with it. History, moreover, is full of instances of reigning houses displaced by revolutions, and succeeded by others, which have been considered legitimate, on account of their acceptance by the people.

\*The word *legitimacy* is now commonly used, in Europe, to denote the lawfulness of the government, in a hereditary monarchy, where the supreme dignity and power pass by law from one regent to another, according to the right of primogeniture. In this sense, Napoleon Bonaparte is called an *illegitimate* ruler of France, though he was acknowledged by the French nation, and by other powers (even by Britain, which negotiated and concluded with him, as first consul, the peace of Amiens). Louis Stanislaus Xavier, on the contrary, as the eldest brother of Louis XVI., is called a *legitimate* ruler of France, because (agreeable to the Salic law, which prevails in the French monarchy), after the death of Louis XVI., his son was to succeed to the throne, under the title of *Louis XVII.*; and, as he died without children or brothers, and his sister could not succeed, his first uncle (formerly count of Provence) was to be considered as Louis XVIII., although the Bourbon dynasty, in fact, ceased to rule at the death of Louis XVI. This signification of the word is plainly too limited; for, 1. it is not adapted to states with elective governments, notwithstanding a regular government is established in them, as well, as in hereditary states, by constitutional laws, and consequently there are legitimate rulers in them; 2. it is not adapted to hereditary states, if the reigning family becomes extinct, when a new family must be called by the nation to the throne, or a different form of hereditary succession be adopted in regard to the persons who are to fill the highest offices of dignity and power. But there is an error, also, at the very foundation of the above definition of legitimacy: it supposes that the state, that is, the people living in a certain territory, in civil union, is the private property of a single family, transmissible, like all other private possessions, from the parents to their children, or other relations, as long as any branch of the family is living; for one man can never, rightfully, be the property of another—still less a multitude of people, in civil union, or a state. If the idea of property was applicable in this case, the ruler ought rather to be called the property of the state, than the state the property of the ruler; but the idea does not admit of being applied to the relation existing between a state and its governor. This relation can be properly considered only as a contract by which the dominion of the state is given to the ruler, whether the compact be merely virtual and tacit, or express and formal, and whether the supreme power is given to a definite individual, who is appointed anew every time, or to a whole

\* What follows of the article Legitimacy from this point, must be taken as the view of Continental jurists on the subject.

family, from which the rulers are to succeed one another, without a fresh choice, in order to prevent the dangers attendant on frequent elections. But there is another and more comprehensive signification of the word *legitimacy*, by which we are to understand the order existing in a state, and established by law, with respect to the form of government, and the persons to whom it is intrusted. The historical origin of this order is not to be taken into the account, but merely the fact that it is established by the law, (which, in theory, expresses nothing else than the universal will, or the will of the people), and has thus gained the form of a right. If we look to history, we shall find few governments that have a claim to legitimacy as having been lawful in their origin. As regards the Bourbons, it is well known that Hugh Capet, the founder of the third dynasty of the French kings, from whom also the Bourbons descended, gained the French throne, to the injury of the existing sovereigns, by his courage and ability, in the tenth century. If it is asserted that illegitimate authority was made legitimate by being transmitted from one person to another, then it must be conceded, that, if Napoleon had died before his abdication, and left the power to his son, the latter would have been a legitimate sovereign of France, and consequently there would have been two legitimate dynasties in the kingdom—the Bourbon and the Napoleon; but it is not easily understood how mere transfer can make that power legitimate which was at first illegitimate. It cannot be considered the same as prescription (*prescriptio*); for prescription only takes place when a positive law, relating to the rights of private persons, has fixed a certain period, within which some result takes place; but neither national law, nor the laws of single states, fix any kind of prescription in regard to the rights of a government. A ruler, in truth, becomes legitimate, if the people submit to him, and thus in fact, if not formally, consent to cede to him the supreme dignity and power; but this was the case with Napoleon. The French people acknowledged him their sovereign—first under the title of *first consul*, and afterwards under the title of *emperor*; and the state of things thus established in France, was approved even by foreign powers. The French nation cannot have been forced to submit to him, because, when he took the reins of the government, he had come from Egypt without an army, and his power was far too small to subdue the whole French people. Grant that one party was unjust in declaring the family of Louis XVI. to have forfeited the throne, still the French princes, by their flight from France, had, in a manner, banished themselves, and resigned their claims to the throne; for these claims could not be maintained by words merely, but required action. They were not permitted to leave the king, with whose person all their rights were connected; on the contrary, they were bound to defend his person and his rights, as a sovereign, even at the peril of their lives. But as they regarded only their own safety, and deserted France and its rose, it might easily be shown that they, in fact, renounced their claims, and even promoted that anarchy, from which none but a mighty hand could rescue their country. If now France acknowledged and delivered (for such Napoleon, at that time, indisputably appeared) as its monarch, because the old dynasty suffered its claims to be overlooked, what is wanting to make him a legitimate sovereign? At this legitimacy was wanting, when, on his return from Elba, he undertook to resume the throne of France; for in this case, he overthrew an existing political order, and occasioned a kind of anarchy. A large part of France formally withstood him, and refused to send representatives to the *champ de Mai*,

where he intended to establish his legitimacy. Moreover, no foreign power recognised his authority. What the event would have been if Napoleon had prevailed at Waterloo, cannot be determined; but it is certain that the modern French theory of legitimacy would have been subjected to the greatest difficulties. This theory, however, has never been reduced to practice, but only the more limited one above-explained, as is proved by history in general, and, particularly, by the history of Britain, where the throne of the Stuarts is now occupied by sovereigns, whom all the world looks upon as legitimate, though, till the death of the last pretender, they must have been viewed, according to the ultra theory, as illegitimate. This leads us to the conclusion, that the proper point of view for considering legitimacy, at present, in Europe, is not, in relation to the lawful title to power, but only to its actual existence; and that the national law of modern Europe, while it aims to put an end to the convulsions of the last thirty years, is founded on the support of the present state of things, with the changes confirmed by the unanimous consent of the principal European powers. Hence arises a very definite notion of legitimacy, wholly free from the difficulties which occur in accounting for the lawful origin of power. For, on this ground, it is no longer necessary to show how a national government and dynasty was established in early times, but only that it is now acknowledged. The acknowledgment is that of the European powers, so called by way of eminence; that is, according to the use of the term since the congress of Vienna, in 1815, of all those states which do not depend entirely for their existence on a federative union; or of the eight powers which signed the peace of Paris; or, in a more limited sense, of the five powers which sent their commissioners to the last congress. In this practically admitted signification, legitimacy relates not merely to the dynasty, but also to the forms of government. It holds strict monarchical principles, as a general rule, and allows only the few actually existing exceptions; but it would be impossible to acknowledge an antimonarchical change, even though it were proposed voluntarily by the sovereign himself; for with this idea of legitimacy is closely connected the right of the European powers to prevent by force of arms, any alterations in the government, which are opposed to the monarchical principles of other states; and as, in this, it has reference only to the dangers which may accrue to other states from the establishment of republican institutions in any one, it considers only the fact of their existence, not the manner of their origin. The right of armed interference in the internal affairs of foreign states, it is well known, has never been disputed, but by Britain and America. Indeed, it has been maintained even by philosophers (Kant, *Zum ewigen Frieden*—On perpetual Peace) who make it a fundamental article of international law, that no state should be without a representative government. This right of armed intervention, however, admits of serious question: if it was once acknowledged, it might be used, also, by republics. In addition to the importance of the doctrine of legitimacy, in regard to subjects of international law, it is equally important as respects the internal government of a state; as it depends chiefly upon this to decide how far the acts of a government, merely usurped, can be obligatory on the legitimate government, if it should be again restored. This obligation can neither be maintained nor denied, unconditionally. It is impossible to declare all those acts of the public authority, which have taken place during a long usurpation, invalid. It would be equally absurd to treat as absolutely unalterable all abuses of justice (confiscations, penal laws, attacks

upon the private property of the legitimate ruling house) by which the usurpation was attended. If the previous sovereign, therefore, is deposed, no one can refuse to the people the right of submitting, at least for a season, to that power which has been established in the place of the legitimate government, especially when the latter has ceased to struggle against the usurper, or continues its resistance without sufficient means. This principle was nowhere expressed so early and so decidedly as in Britain; for nowhere has there been such a variety of governments, which were afterwards declared to be mere usurpations, as there, during the contest, for sixty-four years, between the houses of York and Lancaster, and, subsequently at the time of the commonwealth and of Cromwell. Hence the British early learned to distinguish actual sovereignty (government *de facto*) from legal government (government *de jure*), and laid down the position, that subjects were bound to yield obedience, even to a usurper, as long as he is in full possession of public power, and that they are equally guilty of high treason in forming conspiracies against such a usurper, as against the lawful monarch. (This is said by Sir Matthew Hale, in his Pleas of the Crown, i. 80; Blackstone, Commentaries, i. 370, and iv. 77.) Accordingly, under Edward IV. of York, when he had deprived the house of Lancaster of the throne, in the person of Henry VI., persons were punished, who had been guilty of treason against the last king of the deposed house; and an express law of Henry VII., in the year 1495, declared all persons innocent, who had promised or yielded obedience to the king *de facto* (the usurper). Although Charles II. numbered the years of his reign from the death of his father (Jan. 30, 1649), yet all the acts of the interregnum remained in full force, unless they were necessarily repealed by the enactment of new laws. In France, at the restoration, the statesmen were obliged to adopt the same principle. The idea of legitimacy is to be considered, moreover, in reference to the limits of the power of sovereigns, as well the natural and universal, as the positive or conventional. Even the ancients distinguished tyranny—power without a just foundation (*tyrannis abque titulo*, or usurpation)—from the unjust use of power in itself legitimate (*tyrannis exercitio*); and, if legitimacy is once viewed as a principle of national law, it must necessarily be as much an object of support, in this latter relation, as it is against usurpation and revolution. The maintenance of the existing state of things is as much required in this view as in the others, and for a higher purpose. If the European powers are justifiable in maintaining their monarchical principles, they are no less authorised to maintain them in their purity; that is, as the means of legal authority, and to prevent the ruin of those institutions by which they are to be kept from degenerating into despotism; or, if these institutions have already been destroyed, to renew them, as prudence and the spirit of the times will allow. This authority, which may be deduced from a necessary duty, they have particularly when it is requisite to support an existing government, by arms, against usurpation or the violence of the mob. When this view of legitimacy finds place among the practical principles of national law (and it cannot be said to be rejected, as much has already been done in its spirit), an important step will have been made towards the accomplishment of the grand project of universal order, a universal tribunal, and universal peace. See Malte Brun's *Traité de la Légimité*, &c., Paris, 1825; and the articles *Aix-la-Chapelle*, *Congress*, *Holy Alliance*.

LEHMANN, JOHN GEORGE; a major in the royal Saxon army, and the inventor of a method of topo-

graphical drawing, which is called after his name. He was the son of a miller in humble circumstances, and born May 11, 1765, at Baruth, in the former Saxon electorate. His early education he received from the village smith, and afterwards worked in the mill. The recruiting officers, who often attacked the lower class of people in disguise, waylaid him, and carried him off to their quarters, as he was going to church. Lehmann soon distinguished himself by his industry and skill in writing and drawing. In 1793, he obtained his discharge, in order to devote himself entirely to topographical labours, and surveyed about 500 square miles in the Ennsperg, together with several private estates. The want of the common facilities for surveying, led him to the invention and application of those important instruments, which are found in the second volume of his work. Lehmann also gained much experience in regard to the origin and constitution of single elevations, and of mountainous chains, and afterwards founded upon it his mode of topographical drawing, translated into English by Siborn. He made the campaign under Napoleon, in the Saxon army, and performed important services. Napoleon held him in high estimation. By constant application to his profession, he contracted a disease which finally terminated his life. Sept. 6, 1811. His system is of great importance to the soldier. It was published, after his death, by professor Fischer, with Lehmann's last improvements.

LEIBNITZ, GOTTFRIED WILHELM, baron &c., one of the most celebrated scholars and philosophers that Germany has ever produced, was born at Lempitz, July 3, 1646. His father, who was professor of jurisprudence in that city, died before he was half completed his sixth year. Leibnitz attended the school of St Nicholas, in Leipzig, till he was fifteen years old, without, however, adhering strictly to the prescribed course, as he was devotedly attached to Livy and Virgil, among the Latin writers. The latter he knew almost entirely by heart, and, even in his old age, he used to repeat whole books of his poems. He was soon distinguished for rapidity of comprehension and facility of expression. At the age of fifteen years, he began his academical course in Leipzig, and, although his principal study was ostensibly law, he paid particular attention to mathematics and philosophy, at that time taught by Johann Thomasius. He passed one year at Jena, in order to avail himself of the instructions of the celebrated mathematician Erhard Weigel. After his return to Leipzig, he studied the Grecian philosophy. He gave a splendid proof of his progress, in his philosophical dissertation *De Principio Individuationis*, which was defended under Thomasius (1664), and which was followed by several legal treatises, e. g. *De Conditionibus* (1665), and by a remarkable philosophical-mathematical treatise, *De Arte combinatoria*. In his twentieth year, he presented himself to the legal faculty, as a candidate for a doctorate, but was refused on account of his youth, and received his degree at Altorf. He was offered the place of professor extraordinary of law, in that university, but he preferred going to Nuremberg, where there were many distinguished men. The famous Valentin Boineburg, minister to the elector of Mainz, having become acquainted with him, withdrew him from a society of alchemists, in that city, with which he had connected himself, and, promising him a place in the service of the elector, induced him to fix himself at Frankfurt on the Maine. Here appeared in 1686, his *Nova Methodus discendi doctrinam Jurisprudentiæ*, which is remarkable for its clear and, at the same time, profound views, and which, at the request of his patron, was soon followed by a treatise, in which he endeavoured to prove to the Pope, that

it was for their interest to elect the prince of Neuburg king, in preference to any of the other candidates. At the suggestion of Boineburg, he was now named an electoral counsellor, and chancellor of justice; but this business could not satisfy a mind thirsting for knowledge. He continued his literary labours, and published his *Theoria Motus abstracti*, and *Theoria Motus concreti* (1671,—two physical inquiries, remarkable only for the boldness of their views), and also his *Sacrosancta Trinitas, per nova Argumenta logica defensa*, a work directed against the attacks of the Pole Wissowatius, on the doctrine of the Trinity. In the mean time, the literary splendour of Paris had attracted his attention, and he willingly undertook to accompany the young Boineburg thither (1672). The distractions of this capital did not draw him from his studies. He applied himself particularly to mathematics, and enjoyed the acquaintance of the celebrated Huygens, whose expectations he answered by the invention of an arithmetical machine, similar to that of Pascal. His patron, Boineburg, died 1673, and Leibnitz, who had nothing to detain him longer in Paris, declined the place of pensioner in the academy, as it would have been necessary for him to embrace the catholic religion, and went to England, where he became acquainted with Wallis, Bayle, Oldenburg, and Newton. He then applied to the duke of Brunswick-Lüneburg, who gave him the office of counsellor, and a pension, with permission to extend his residence in foreign countries at his pleasure. Availing himself of this permission, he returned to Paris, where he spent fifteen months, devoted entirely to mathematics, and then returned, by the way of England and Holland, to Hanover, where he arrived 1676, and immediately entered upon the superintendence of the library, which was his principal duty. Here he soon published his treatise *De Jure Suprematus ac Legationis Principum Germaniae*, and laboured, with great zeal, to effect the publication of the *Acta Eruditorum*. On the death of the duke of Brunswick, his successor commissioned Leibnitz to write the history of his house. In order to consult the documents necessary for that purpose, Leibnitz went (1687) to Vienna, and (as the old counts of Siguria, Tuscany, and Este were sprung from the same source as the house of Brunswick) thence to Italy. The three years which he spent in making these tours of investigation, supplied him with an immense mass of diplomatic and political materials, the smallest portion of which appeared in the work he had undertaken: the remainder was published in 1683 and 1700, under the title *Codex Juris Gentium diplomaticus*, and *Mantissa Codicis*. At the same time, he employed himself in arranging the materials which he had collected for his historical undertaking, and, after having published an essay on the connexion between the houses of Brunswick and Hanover, which procured him the appointments of privy counsellor of justice, and historiographer, he gave to the world (1707—11) *Scriptores Rerum Brunsvicensium* (3 volumes, folio). But this important work was only a preparatory step. The history itself was never published: the outline only was found among his papers after his death, and published in the *Acta Eruditorum* for 1717. According to this plan, we could have had a general account of the primitive condition, not only of Germany, but of the whole world, in conformity with the views given by Leibnitz in his *Protogæa*. (See the *Acta Eruditorum* for 1683.) The *Accessiones historicae*, and the *Dissertationes de Origine Francorum*, were published at Hanover, in 1715. As Leibnitz displayed a profound knowledge of history in the above-mentioned works, he showed a no less intimate acquaintance with geology, in his attempts at forming a plan for

re-uniting the Protestants and Catholics, in which he spent much fruitless labour, in conjunction with Molanus and Bossuet. Among his plans for the good of mankind, may be mentioned his exertions to invent a universal character, and a common philosophical language (*pasigraphy*). His labours in another scientific undertaking were better rewarded. The elector of Brandenburg (afterwards Frederic I., king of Prussia) requested his advice in the establishment of the royal academy of sciences at Berlin, and, when the institution was completed, according to his plan, the elector made him president of the academy (1700.) Leibnitz furnished a great part of the papers in the *Miscellanea Berolinensia*, which the new academy published in 1710. On the death of the king, three years after, his successor having little taste for the sciences, Leibnitz foresaw the fall of the society, and therefore hastened to Vienna, to obtain for it the protection of the emperor Charles VI. His efforts were unsuccessful, although he got a most flattering reception from the emperor, who had already conferred on him the dignities of baron, and of aulic counsellor, with a pension of 2000 foris. He also had an interview with the czar Peter, at Torgau (1711), who, in return for his advice concerning the civilization of his vast empire, conferred on him the title of privy counsellor, with a pension of 1000 roubles. Loaded with honours, he crowned his literary fame by his celebrated *Essai de Théodicée* (1710), in which he maintained the doctrines of pre-established harmony and optimism, and which was followed (1715) by his *Essai sur l'Entendement humain*. The life of this individual, so highly favoured by fortune, was not entirely free from calamity. His unfortunate controversy with Newton, concerning the discovery of the differential calculus, and the pains of the gout, imbibed the close of his active life. He died in his seventieth year, November 14, 1716. His monument, constructed in the form of a temple, bears the simple inscription *Ossa Leibnitii*.

Leibnitz was of the middle size, thin, but of firm health, with an habitual stoop. His hair was black in his youth, but labour early rendered it white; and his eyes, which were short-sighted, were strong, even in old age. He had a pleasing countenance, a warm temperament, and as much animation in his delivery as he had in his labours. He studied during nearly the whole night, and often took his sleep in his chair, which is preserved in the library at Hanover. Reading every thing, without distinction, he contented himself with making short extracts, on little pieces of paper, which he kept in different compartments, though his memory was so excellent that he had little need to refer to them. His correspondence, which extended even to China, together with the other relations which he maintained with different classes of men, took up a great part of his time. In his intercourse with others, he was easy, without arrogance or jealousy; irritable, but quickly reconciled. His expenses were very moderate, and his enemies reproached him with avarice. He was totally negligent of his domestic affairs, and was never married.

The spirit of the age, the study of the older systems of philosophy, among which the Grecian had occupied much of his attention, and, above all, the mathematical turn of his mind, combined to produce his peculiar system of philosophy. He expected to reform philosophy by giving it this direction, and he hoped to establish its principles in such a manner that the strife between different parties would cease of itself. On this account, he was in favour of rationalism (q. v.), in the sense in which it was maintained by Plato, and the system of demonstration, which

prevented him from entirely rejecting the scholastic philosophy. There are in philosophy, as in mathematics, necessary truths, which cannot be learned from experience, but must be grounded in the soul itself, as they rest on principles, the proof of which is independent of the evidence of the senses. This forms the basis of the Leibnizian rationalism, the principal characteristics of which are a peculiar theory of knowledge, the doctrine of Monadology, and the Theodicea, or doctrine of optimism. With regard to knowledge, according to this system—1. The necessary truths are innate in the soul, not, indeed, actually forming objects of knowledge, but capable of being called forth by circumstances. Whatever is derived from the senses is confused, and distinct knowledge is possessed only by the understanding. These views are opposed to the empiricism of Locke. In order to attain truth, it is necessary to use the rules of logic, as mathematicians also use them, by unfolding, analytically, the simple truths contained in a subject, until the fundamental truth is attained. The Cartesian criterion—clearness and distinctness—is not sufficient. "Our conclusions," says Leibniz (*Op.* ii, 24), "rest on two great principles—the principle of contradiction (according to which we deem that false which involves a contradiction, and that true which is opposed to falsehood), and the principle of the sufficient reason (which teaches that no assertion is true, if no sufficient reason can be given why it is true, rather than false), which leads to an absolute final reason, independent of accidental circumstances. But the final reason of the certainty of innate necessary truths is in God, as the source of all necessary and eternal truth. 2. Monadology forms the central point of the system, and Leibniz believed that, in this, he had discovered the fundamental basis of actual knowledge. All experience teaches us that there are compound substances; consequently there must be simple ones. The senses give us only confused, the understanding distinct, knowledge; and the simple, which cannot be recognised by the senses, is the ground of the compound. These simple substances, from which the compound are formed, and each of which differs, in its qualities, from all others, since there are no two things exactly alike, Leibniz calls *monads*, of which he assumes four sorts—pure monads (or living beings), the souls of beasts, the souls of men, and God, who, as the origin of all knowledge, of reality, and of the existence of things, the eternal, original Monad, he calls the *Monas monadum*. All created monads are united with bodies, or, rather, all finite beings are aggregates of monads, some having a central and governing monad. The different classes of monads conceive of the universe with different degrees of distinctness: God alone conceives it perfectly. There is no actual influence (*influxus physicus*) of one thing on another, but only an ideal connexion; i. e. the internal changes of each monad are so arranged as to agree with the changes in the monads immediately connected with it. The cause of this agreement is the infinite wisdom and almighty power of the Deity. The divine understanding is the prototype of all truth, beauty, and absolute good, and by it all the interior changes in the monads were so predetermined, that there is a perfect harmony in their succession. This predetermination or established harmony was arranged by the Godhead when the plan of the world was formed. 3. The Theodicea is the defence of the supreme wisdom of the Creator of the world, which had been impugned, on account of the existence of evil. Such a Theodicea Leibniz attempted, particularly on account of the contrary views brought forward by Bayle. According to the Leibnizian system, an infinite number of

worlds are possible in the divine understanding; but, of all possible ones, God has chosen and formed the best. Every thing which really is, is best in connexion, even if, by itself, it is imperfect. The system is therefore denominated *optimism*. Each being is intended to attain the highest degree of happiness of which it is capable, and is to contribute, as a part, to the perfection of the whole. The existence of evil is no argument against this system, because metaphysical evil is merely a necessary imperfection in the nature of finite things, from whom imperfection, physical evil, (suffering), and moral evil (sin) necessarily proceed. Moral evil is founded on the freedom of finite spirits, which consists in choosing, according to grounds of preference, one among many physically possible actions; for, although every thing in the world is necessarily determined, all man, being ignorant of the future, must act from the convictions of his reason. Leibniz nowhere makes a complete connected exposition of this philosophical system, but has only proposed it in his writings, by piecemeal, and it is therefore difficult to follow in course of thought.

This is not the place to enter into a more critical examination of the value of these hypotheses; it is sufficient to observe, that they have been of the greatest service in promoting the progress of reason, as they have given that impulse to the philosophical world, which his mathematical discoveries, on account of which we now proceed, gave to the mathematicians of his time. His attention was early directed to mathematical researches; and, as a hint to the countess of Kiermannsegg (1716), he remarks that, even in his sixteenth year, he was occupied considering the differences of those numbers whose succession forms a regular series. He then arrived at the law of constant magnitudes, which is always found exactly, or by approximation, if the number of the series, and then their first, second, &c. differences are subtracted from each other; but, when he was in England, wishing to publish his supposed discovery, he found himself anticipated by a French mathematician, Regnault. A second similar idea induced him to study Mercator's *Logarithmicon*, which he carried with him to France, where he surprised Huygens by communicating to him his discovery of an infinite series for the surface of the circle, similar to that of Mercator for the hyperbola. This was made known by Oldenburg to Verulam, who congratulated Leibniz on his discovery. Inspired by this result, Leibniz resumed his researches into the difference of numbers, and, in this way, he was led to the discovery of the differential calculus. In a letter of June 21, 1677, he communicated the discovery to Oldenburg, for Newton's examination. In comparing the whole course of reasoning which he pursues in his calculations, with the views which lie at the foundation of Newton's method of fluxions, not the least similarity can be discovered between the two methods; which is the best proof that each of these great men, in reality, attained the same result for himself, entirely independent of the other. Leibniz, however, received no answer from Newton to this remarkable letter, and things remained in this state till 1682, when the *Acta Eruditorum* was commenced. Leibniz was, from the beginning, one of its most active contributors, and, in the October number of 1684, he published a complete account of his differential calculus, exactly as he had communicated it to Newton. It is worthy of remark, that, at this time, no one questioned the claims of Leibniz to the discovery of this new mode of calculation. On the contrary, Newton publicly acknowledged the merit of the German, and made the most honorable mention of him in his *Principes*. Leibniz continued

with untiring activity, to make improvements in his method. The differential calculus, together with its converse, which Leibnits called *summatory*, but to which John Bernoulli gave the name of *integral calculus*, was in high esteem on the continent, and had been much used and extended, both by Bernoulli and the marquis de l'Hopital, when, in 1699, twenty-two years after the letter of Leibnits to Newton, which was dated June 21, 1677, and fifteen years after the publication of the theory in the manner already mentioned, in the October (1684) number of the *Acta Eruditorum*, it was contended, for the first time, by Patio de Duillier, that Newton was the discoverer of this mode of reckoning. This article was written in an offensive tone, and Leibnits answered it in the *Acta Eruditorum*. His reply for a time put an end to the dispute; but five years afterwards (1704), Newton, having published his *Optics*, at the close of which he appended an exposition of his method of fluxions, which he claimed to have invented as early as 1666, the *Acta Eruditorum* gave an extract from this work in the next year, and, by making a comparison between the method of fluxions and the system of differential calculus, to the disadvantage of the former, awakened anew the dispute between the parties. Keill, professor of astronomy at Oxford, declared, in the *Philosophical Transactions* for 1708, not only that Newton was the original inventor of the new system, but that Leibnits had formed his upon Newton's merely by changing the expressions and the signs. Leibnits, therefore, wrote to Hans Sloane, secretary to the royal society, to request the society to decide between him and Keill. The society immediately named a committee, who came to the following conclusion, that, in reality, there was no difference between the differential calculus and fluxions, and that the question did not turn on the invention of the one or the other, but on priority, with respect to which there was strong proof that Newton had possessed the system fifteen years before the publication of Leibnits's article in the *Acta Eruditorum*, and that, therefore, Keill's assertion concerning Leibnits could not be considered as a calumny. This decision of the society only rendered the schism between the parties wider; and Leibnits rendered the quarrel irreconcilable, by sending a letter to the abbé Conti, who was then in England, and acted the part of a mediator between the parties. In this letter, which was intended to be shown to Newton, among other offensive expressions, he gave him to understand, that it was impossible that he should have invented the algorithm of infinitely small magnitudes before himself. Newton replied through Conti; and the dispute continued till the death of Leibnits.

Lewis Dutens, secretary of legation in the English service, published the most complete and accurate edition of the works of Leibnits—*Go. phil. Leibnitii Opera omnia* (Geneva, 1768, six volumes, 4to). In Dutens' edition, however, all those philosophical works are omitted which Raspe published (Amsterdam, 1760, 4to), under the title *Œuvres philosophiques de M. Leibnitz*. Both collections should be united. Dutens did not accomplish his undertaking without great difficulty, and he describes, in a very interesting manner, the obstacles encountered in collecting writings so numerous and so widely scattered, and his correspondence on the subject with Voltaire, in his *Mémoires d'un voyageur qui se repose* (volume i. p. 248). Eccard, an intimate friend, and, after his death, librarian at Hanover, first wrote the life of this extraordinary man, who had surveyed the whole field of science with a penetrating eye. We have also eulogies on him, by Kastner (1769), by Bailly and Fontenelle.

LEICESTER; a town of England, the capital of Leicestershire, situated on the Soar, in the centre of the finest wool district in the kingdom, ninety-six miles N. N. W. of London. The chief manufacture is that of combing and spinning wool, and making it into stockings; and, in this business, it is, except Nottingham, the principal town in the kingdom. Population, in 1831, 39,306.

LEICESTER, EARL OF. See *Dudley, Robert*.

LEICESTERSHIRE; an inland county of England, bounded on the north by Derbyshire and Nottinghamshire; on the south by Northamptonshire; on the east by Lincolnshire and Rutlandshire; and on the west by Warwickshire and Derbyshire. It extends from north to south about thirty miles, and from east to west about twenty-five. The greater part of this county presents nearly a level surface, and the land is chiefly appropriated to the purpose of grazing. The soil consists generally of a fine mixture of sand and clay. The rivers of Leicestershire are, the Soar, the Wreak, a branch of the Soar, the Swift, the Welland, the Avon, and the Anchor. With the Soar, the Wreak, and other streams, are connected various navigable canals, which have been constructed for the benefit of commerce. The principal mineral products of the county are coal and limestone; the mines are situated near the borders of Derbyshire. In some parts the limestone is blended with rich lead-ore. At Swithland, on the east side of Charnwood Forest, are raised large quantities of slate; and freestone and clay for bricks may be found in most parts of the county. The hill of Mountsorrel is composed of a reddish kind of granite, which hardens on exposure to the atmosphere, and forms an admirable article for street pavements. In digging for coal on Ashby Wolds, saline springs were discovered 200 yards below the surface, and baths have since been erected on the spot.

Leicestershire is famous as a grazing country, for breeding and feeding cattle and sheep. The Leicestershire sheep are particularly noted, and the Leicestershire kine are also greatly esteemed in most parts of the kingdom. The principal object of the graziers is to fatten their cattle for the butcher; but in some parts of the county, as Hinckley, Bosworth, along the Trent, on the borders of Derbyshire, and in the vale of Belvoir, the dairy is much attended to. In the neighbourhood of Melton Mowbray is now made the peculiar kind of cheese called Stilton, deservedly styled for its excellence the Parmesan of England. Leicestershire has long been noted for a useful and beautiful breed of black horses, comprising varieties for the plough and the wagon, or for the race-course and the chaise. It is, indeed, one of the first sporting counties in England; several noblemen and gentlemen keep hounds, and the meetings during the hunting season are numerous and well attended. To provide food for the horses and stock of the farmer, more than half the land is constantly kept in pasture, and the remaining part is chiefly appropriated to the production of grain and other food for cattle. The staple manufacture of Leicestershire consists in the combing, spinning, and making of wool into stockings, either by knitting or weaving. The principal articles of commerce are cheese, worsted hose, hats, lace, and wool; besides great numbers of cattle and sheep, which are sent to London, Birmingham, and other places. The market-towns are Ashby-de-la-Zouch, Billasdon, Market Bosworth, Castle Donnington, Hallston, Market Harborough, Hinckley, Loughborough, Lutterworth, Melton Mowbray, and Mountsorrel; besides the borough of Leicester. Population of the county in 1831, 197,003.

LEIGHTON, ROBERT, an ecclesiastic of singular learning, integrity, and benevolence, was born in Edinburgh in 1611, and received his education at the university there, which he entered as a student in 1627. He was subsequently sent to France, and, on his return, obtained Presbyterian ordination, and was settled at Newbottle, near Edinburgh. Disapproved of by his Presbyterian brethren, as not sufficiently polemical in his discourses, he resigned his living, and was soon after chosen principal of the university of Edinburgh. When Charles II. resolved to re-establish episcopacy in Scotland; Dr Leighton was induced to accept a bishopric, but chose the humblest of the whole, Dumbfries, and would not join in the pompous entry of his brethren into Edinburgh. He, nevertheless, became archbishop of Glasgow, chiefly impelled, it is believed, by a hope of furthering a scheme of reconciliation between the Presbyterians and Episcopalians. Disappointed in this hope, as also in his wishes to moderate the acrimonious feelings of both parties, he went to London, and requested leave to resign his see; but his resignation was not accepted. He, never, however, returned to Scotland, and died in London, Feb. 1, 1684, in the seventy-first year of his age. Archbishop Leighton was celebrated for his gentleness, moderation, and disinterestedness; for, although his bishopric produced only £200, and his archbishopric barely £400 per annum, he founded exhibitions both in the colleges of Edinburgh and Glasgow. As a preacher, he was admired beyond all his contemporaries, and his works have not yet lost their popularity, a complete edition of them having been published in 1808 (6 vols. 8vo.), with a life of the author.

LEIPSIK (properly, *Leipzig*). There is, perhaps, no city in Europe of its size and population, so important in a literary, commercial, and historical connexion, as Leipzig. At the end of the tenth century, a little Slavonian village stood in the angle formed by the confluence of the Parde with the Pleisse. It received its name from the numerous lindens (*Scalvonic, lip, lipa*) in the neighbourhood. The first mention of Leipzig, as a fortified city, with walls and ditches, is in the twelfth century, in the time of Otho the Rich, who established the two fairs of Easter and Michaelmas. The bull which Alexander V. issued in 1409, for the establishment of the university, calls it "the populous and spacious Lipak." The city itself, at that time, was probably of the same extent as at present, for the ditch surrounding it existed in 1454. But during the peace which followed the seven years' war, the fortifications fell into decay, and the ditch was converted into a garden, which, instead of ramparts, encircled the whole city. With the increasing prosperity of the citizens, the city received new embellishments. Leipzig stands in a large plain, which is fertile, and enlivened by thriving villages. According to Oberreit, the observatory is situated in lat.  $51^{\circ} 20' 19''$  N., lon.  $12^{\circ} 21' 45''$  E. Population, 41,000. The plains of Leipzig are watered by four rivers—the Pleisse, the Elster, the Parde, and the Luppe. The city has four gates, and is divided into four quarters, containing seven squares, six principal streets, and twelve small streets. The principal public buildings, some of which are fine specimens of architecture, are, the town-house, built in 1599, the exchange, the churches of St Thomas and St Nicholas, the St Thomas school, the Auerbach court, the Pleissenburg with the observatory, the cloth hall, &c. Among the inhabitants are many descendants of the fugitive Huguenots, Italians, and some Jews, enjoying protection. The commerce of Leipzig, which draws foreigners from almost all nations to the great fairs, has

not, indeed, the extent which it had thirty years since, but it employs, nevertheless, directly, or indirectly, the majority of the inhabitants. Between 8000 and 9000 purchasers assemble at the great fairs. The principal articles are horses (400 to 800 select animals is the average number offered for sale), peltry, cotton stuffs and cotton, wool, animal products, English and French goods, and the productions of the Erzgebirge, books and works of art. There are, in the city, about 300 retail dealers, and 800 wholesale merchants. Traders often come hither from distant countries—Greeks, Russians, and even Persians. The book-trade of Leipzig is unique. Every German publisher has an agent there, who receives and disposes of his publications. The agents send packages of books, twice a week, to all parts of Germany. Twice a year, a book-fair is held at Leipzig, which is attended by booksellers from all parts of the country. Some French, Russian, and British booksellers are also present. The Leipzig annual catalogue of books shows the immense number that are written in Germany. Manufactures, in general, have been pursued with little success at Leipzig; but the manufacture of gold and silver thread, of tobacco, of playing cards, oil-cloth, besides printing and type-founding, have profably employed, for years, a large number of workmen. The university library, of about 60,000 volumes, with 1600 manuscripts, is principally rich in the philosophical and medical departments, as well as in ancient theology. It was formed from the libraries of the suppressed monasteries. The public library, founded in 1605, contains valuable treasures of history and jurisprudence. The collections of paintings of Spitz, Keil, and other private individuals, are uncommonly extensive and easily accessible to amateurs. To the young musician, Leipzig affords great opportunities of improvement. The principal productions of modern instrumental music are here heard in great perfection. For centuries have the two learned schools of St Thomas and St Nicholas been celebrated. Gesner, Ernesti, Fischer, Reiske, were educated here. The university was founded, in 1409, by a great number of the students from Prague, with their teachers, on which occasion the elector Frederick the Quarrelsome, and his brother William, took, as the models of the new institution, the universities of Prague and Paris. Many of the most famous scholars of Germany have taught in this institution, which now numbers 1300 students and upwards of twenty professors. Botanical gardens, hospitals, and other necessary establishments, are connected with the university.

LEIPSIK, BATTLES OF. Twice have the destinies of Germany been decided by arms on the plains of Leipzig—Sept. 7, 1631, and Oct. 18, 1813; and the battle of Nov. 2, 1642, was by no means unimportant in its consequences. In the battle of Sept. 7, 1631, the military talents of Gustavus Adolphus, and the superior tactics of the Swedes, prevailed over the Catholic German generals, Tilly and Pappenheim, and Tilly was shown not to be invincible. Of his army of 35,000 to 40,000 men, 8000 fell, 3000 were taken prisoners. The victory was decisive, and Protestant principles triumphed in North Germany. In this battle, the Swedes made good use of their leather cannons. Eleven years after, in 1642, Gustavus defeated, at the same place, the Imperial Saxon troops, under the arch-duke Leopold William and Piccolomini. But the battle of 1813 was most remarkable for its extent and duration, the magnitude of the contending armies, and the importance of its consequences. For the campaign of 1813, the allied powers had formed the plan of operating on the flanks of Napoleon, and uniting in his rear.

With this view, the movements of the Silesian army, under Blücher, and of the northern army, under the crown prince Charles John of Sweden (Bernadotte), were directed to the Lower Elbe, and the movements of the main army, under Schwartzburg, to the Upper Elbe. Circumstances finally determined the country around Leipsic, as the place where the junction should be formed, and Napoleon cut off from the Saal. In all probability, Napoleon was well aware of this project, but expected to frustrate it. A rapid march between the Mulda and Elbe, a quick passage over the latter river at Dessau, ostensibly with the view of advancing upon Berlin, were to deceive and retard the northern army, and give Napoleon time to turn against Schwartzburg, and drive him to the mountains of Saxony. If he was conquered, Blücher and John were to be defeated and destroyed. In conformity with the plan of the allies, the great Bohemian army, of 120,000 men, marched, on the 12th of October, in three columns, against Leipsic, over the Erzgebirge. Napoleon, meanwhile, assembled his troops in and around Leipsic. October 15, he mustered his army, and gave the generals their orders. His whole force amounted to 80,000 or 90,000 men, the corps of Ney and Regnier being still on the road, or employed, under Marmont, to cover the country to the northward. In case of an unfortunate issue, the corps of Bertrand was to secure the pass of Lindenau. Prince Schwartzburg commanded the allied forces, although the three monarchs of Austria, Prussia and Russia were present. His purpose was an attack, with three columns, on the position of the French. About seven o'clock in the morning of the 16th, the allied troops put themselves in motion, carried the French outposts, at the villages of Markleburg, Wachau, and Liebertwolkwitz, and evidently pressed on the enemy's position. The corps of Victor was obliged to relinquish Liebertwolkwitz to general Klenau. About nine o'clock, the battle had become general, and the thunder of innumerable pieces of artillery was scarcely ever heard so powerful and so uninterrupted by the oldest soldiers. Both parties displayed the most brilliant courage. The movement of the left wing of the allies suffered considerably from the firmness of the Poles, who resisted every attempt to cross the Pleisse, and, favoured by the ground, kept up an effective fire. Napoleon ordered, in person, the battle on the heights of Liebertwolkwitz. Macdonald carried the *Swedish camp*, as it was called, by storm, and thus secured to the left wing of the French an essential advantage; but Wachau was the scene of the most obstinate conflict. From this place Napoleon attacked, repeatedly, the centre of the allies. The corps of Ney, which arrived at this juncture from Delitzsch, might have decided the day, but Blücher's army also came in sight. It had pressed forward, from Halle to Skeuditz, on the 16th of October, attacked the duke of Ragusa at Wahren, Lindenthal and Breitenfeldt, gained a decisive victory at Mockern, after a severe resistance, and now threatened Leipsic from his quarter. Ney had, consequently, to be detached against it, and the decisive moment was lost: the emperor Alexander even recovered a lost battery, by the attack of his regiment of Cossack uards; the Russian grenadiers restored the balance of power between the Pleisse and Wachau; and, notwithstanding Napoleon caused the bells of Leipsic to be rung in honour of his victory, he had acquired no advantage by it, with the exception of a small portion of ground, so that the two parties were very nearly in the same position, in the evening, before the battle. But the arrival of the northern army, which Napoleon had not in the least expected,

but of which he was aware before the allies, made him desirous to retreat. On the 17th of October, the arms of the contending forces were permitted to repose, by a tacit agreement; the allies waited for the arrival of their third main body, under Bennigsen, from Dresden, by way of Grimma, and Napoleon was meditating an honourable retreat, for which purpose he attempted to open negotiations with the allies, by means of the captive Austrian count Meerfeldt. He is said to have proposed an armistice, demanded permission to cross the Saal without opposition, proffered the cession of the fortresses of the Oder and Vistula, and manifested an inclination for peace. From these measures, the allies ascertained his weakness, and refused to listen to the proposals, particularly as they were now informed of the arrival of the northern army, before which Ney and the duke of Ragusa retreated, over the Parde, to Schonfeld. Napoleon was thus reduced, on the 18th, to the necessity of sustaining a defensive battle, and was compelled to retreat. He took a position more in the rear, between the Pleisse and Parde, protected by several villages. The northern suburbs of Leipsic were defended by a battery, and by Dombrowski and the duke of Padua (Arrighi). Bertrand still kept the pass of Lindenau open, by which all the unnecessary wagons were quickly conveyed to Lützen. Napoleon himself took his station in the midst of his guard, at Probstheida, that he might send aid to every weak point, and be able to superintend the whole. According to their plan of the 16th, the allies aimed at a junction with Bennigsen and the northern army. They soon found themselves on a more favourable ground, which gave complete efficiency to their cannon and musketry. They gained various successes, and effected a union with Bennigsen. Notwithstanding his ill fortune, Napoleon was able to fill the chasms, and repair his disadvantages; his line was nowhere broken, nor was he ever assailed in the rear; the force of the allies was gradually exhausted, and a fair retreat seemed possible for the French; but it was difficult, on account of the want of a free passage for the columns, because all the ways leading to the western suburbs of Leipsic, and beyond, to the narrow pass of Lindenau, were covered with flying baggage wagons, and troops in great confusion, and no bridges over the Pleisse had been prepared for such an event, and no precautions had been taken. It was but a short time before, that Leipsic itself had been slightly fortified, and the garden walls of the suburb, and similar objects, had been transformed into means of defence. Poniatowsky and Macdonald were now appointed to cover the retreat, which took place at daybreak, 19th October. Hardly had the allies observed that the position of the French was abandoned, when they made preparations to assail Leipsic on all sides, and, after a severe struggle, obtained possession of two gates. To give a faithful picture of the cruel confusion of this retreat, through the city and environs, would be impossible. Every moment increased the disorder of the flying army, and, the only bridge over the Elster having been blown up too soon, the flight was changed into wild desperation. But a short time before, had Napoleon himself, after taking leave of the king of Saxony and his family, reached that important bridge, not without difficulty, and by a circuitous route: 15,000 or 20,000 men, in close array, more than 200 pieces of artillery, and an immense quantity of baggage, were left, and increased the trophies of the victors. Poniatowsky's and Macdonald's hands attempted to escape over the narrow bridge of the Pleisse, and then, hemmed in again by the

Elster, to construct a foot-bridge in the gardens of Reichenbach; but it was not sufficient for the mass which crowded over it. The greater part perished in the waters of the Pleisse or the Elster, in which Poniatowsky found a noble death. The rest fell by the hands of their pursuers. Macdonald escaped. By degrees the resistance slackened; the Baden troops were unable to hold the interior of the city, and the allied monarchs entered at the head of their soldiers. The loss of the French in prisoners, killed, and wounded, has been rated at 60,000 men. Among them, 3000 officers, 300 pieces of cannon, and an immense quantity of baggage, &c., fell into the hands of the allies. The battle of Leipsic is said to have cost the victors 45,000 men (viz. 8000 Austrians, 21,740 Russians, 14,960 Prussians, and 300 Swedes.) With Napoleon's defeat at Leipsic was connected a series of consequences of immense historical importance. See the articles *Saxony*, and *Russian-German War*.

LEISEWITZ, JOHN ANTHONY; a German writer, whose tragedy *Julius of Tarentum* (1776) is esteemed by the Germans one of their best productions, and is still performed. Leisewitz was born 1752, at Hanover, and, at the university, was a friend of Voss, Holty, Burger. He died in 1806, at Brunswick. He burnt the manuscript of his history of the thirty years' war. His works appeared at Vienna, in 1816.

LEISTENWEIN. See *Franconian Wines*.

LEITH; a town of Scotland, in the county of Edinburgh, formerly called *Inverleith*, is situated on the banks of the water of Leith, at its confluence with the frith of Forth, about a mile and a half north-east of Edinburgh, and constitutes the port or harbour of that city. It is divided into two districts, called *South* and *North Leith*, communicating by two draw-bridges across the harbour. The town is mostly situated on the south side of the river, and, with the exception of the modern and improved streets, is irregularly built, with narrow streets and lanes, and the houses mostly old-fashioned and inconvenient. In 1800, a magnificent suite of wet docks was planned, and two of these beautiful basins are now opened for shipping. These docks, comprehending nearly eight acres, together with three graving docks, have cost about £285,000. Fortifications were erected by Oliver Cromwell in North Leith, called the *citadel*, for the purpose of defending the harbour, which were afterwards demolished. There is a martello tower about a quarter of a mile from the pier. About 1783 a battery of nine guns was erected to the west of the site of the citadel, in consequence of an alarm from the American privateer officer, Paul Jones, who appeared before the town with three armed ships only, and threatened to destroy all the vessels in the road and harbour. The battery has been since enlarged, forming a kind of fort, garrisoned by the royal artillery. Leith carries on an extensive trade with the Baltic, and other places in Europe, such as Holland, France, Spain, Portugal, and the Mediterranean; also with the West Indies and America; besides a great coasting trade to the different parts of England and Scotland. A trade has also commenced with New South Wales, with which distant colony a regular intercourse is maintained. The Greenland fishery is also prosecuted with great activity. Vessels of very great burden cannot enter the port of Leith, the depth of water in the harbour at spring tides being but sixteen feet, and only nine feet at neap tides; but the roads, about a mile from the mouth of the harbour, afford excellent anchoring ground for ships of any size. The number of ships which entered this port and paid duties in 1824, was 222 British and 146 foreign; and the number of vessels belonging to the port in 1829 was 263, the

collective burden of which amounted to 28,382 tons. Leith has extensive rope-works, glass-works, and various other manufactories. Ship-building is carried on to a considerable extent; and there is a large distillery in the neighbourhood. Population in 1831: *North Leith* parish, 7,416; *South Leith* parish, 14,639.

LEKAIN, HENRY LOUIS; a French tragic actor was born at Paris, in 1728. It was the intention of his father, a goldsmith, to bring him up in the same avocation, in which the boy made such progress, that his work was in request even in his sixteenth year. He enjoyed, at the same time, the benefit of instruction in the *collège de Mazarin*, where the scholar performed a dramatic piece at the close of the academic year. The means of Lekain were inadequate to the expense required of the performers, and he therefore undertook the office of prompter. He rarely had occasion to make use of the book, so deeply were the plays impressed on his memory, so soon as he had heard them a few times. His games recreation consisted in attending the French theatre on Sundays. Social amusement having acquired life in Paris, after the peace in 1748, several private theatres were formed, and Lekain joined with a number of young persons in establishing one, which was surpassed all the others. Lekain was distinguished for his acting, and Arnaud Baculard's comedy *Le Mauvais Riches* was first performed by this company. Voltaire, Arnaud's patron, was present at the representation, and invited Lekain, who played the part of the lover, to his house. The young actor was embarrassed before this celebrated man, who encouraged him with the words, "Heaven be thanked, I have at last found a person who has moved and touched me, even when reciting bad verses." Voltaire advised him, however, not to become an actor, but in order to induce him not to abandon the trade of his father, offered to advance him 10,000 francs, in order to place him in a more convenient situation. Lekain hesitated, but his propensity for the stage predominated. When Voltaire perceived that the resolution of the young man was irrevocable, he offered to spare him at least the expense of apprenticeship, and to build him a theatre in his own house, where Lekain could play with his young friends. Lekain now lived with Voltaire, whose two maids played with him, and the poet himself sometimes undertook a part. The most distinguished men aspired to the honour of attending these performances. The part of Cicero, in the *Rome Preserved*, was here represented by Voltaire, with an energy and warmth which tradition still preserves the memory, and inspired by such a model, Lekain shone in the character of Titus. During the six months which he spent in the society of Voltaire, his dramatic talent was vastly improved, and, in his *Mémoires de H. Lekain*, published by his son (Paris, 1808; new edition. *Précédés de Réflexions sur cet Artiste et sur l'Art théâtral*, par Talma, Paris, 1825), he says that, at that time, he studied most profoundly the principles of his art. Before departing for Berlin in 1758, Voltaire obtained for his protégé permission to appear on the *théâtre Française*. One of his most splendid parts was Mahomet, in Voltaire's play of the same name. Voltaire called him the only truly tragic actor. His last performance, in the character of *Vandus*, in Voltaire's *Adélaïde*, was admired above all, and the exertions which he made, on this occasion, was the prime cause of his speedy death, in 1778. An inflammatory fever brought him to the grave a few days. On the day of his death, Voltaire returned to Paris, after an absence of thirty years, and the first news which he learned was the distressing information of the death of his protégé.

LELAND, JOHN; an English antiquary, born at

London, about the end of the reign of Henry VII. He was educated at St Paul's school, and Christ's college, Cambridge, whence he removed to Oxford, and then to Paris, for further improvement. Returning home, he took holy orders. Henry VIII. made him his chaplain and librarian, and gave him the title of royal antiquary. In 1533, he was empowered, by a commission under the great seal, to search for objects of antiquity in the archives and libraries of all cathedrals, abbeys, priories, &c.; in consequence of which, he spent six years in travelling over the kingdom, visiting the remains of ancient buildings and monuments, and collecting materials for the illustration of the history and archaeology of England and Wales. He retired to his house in London, to arrange and methodise the stores of intelligence which he had collected, but, after about two years, died insane, in 1552, without having completed his undertaking. The great bulk of his collections, after passing through various hands, was placed in the Bodleian library, in an indigested state. Hearne printed a considerable part, forming the *Itinerary of John Leland* (nine vols. 8vo), and *Lelandi Antiquarii de Rebus Britannicis Commentaria* (six vols. 8vo).

LELY, SIR PETER, a celebrated painter, was born at Soest, in Westphalia, in 1617. His father, a native of Holland, whose family name was Van der Vaes, was a captain in the garrison of that town, but, having acquired the nickname of captain Le Lys, or Lely, his son retained it as a proper name. He was first instructed by Peter Grebber, at Haerlem, and, attracted by the encouragement afforded to the arts by Charles I., he went to England, in 1641, and commenced portrait-painter. He finished portraits both of that monarch and of Cromwell; but it was not until the restoration, that he rose to the height of his fame and prosperity. He fell in with the voluptuous taste of the new court, in his representation of the beauties who adorned it, and, by the delicacy and grace of his pencil, became the favourite ladies' painter. He has transmitted the features of most of the beauties of the court of Charles II., and is particularly admired for the grace of the heads and the elegance of the draperies. He was in great favour with Charles II., who knighted him. He died in 1680. The "beauties" at Windsor, by him, are much admired. He likewise excelled in crayon painting. His historical pictures are few. At Windsor, there is a Magdalen and a sleeping Venus. The duke of Devonshire has his Jupiter and Europa; lord Pomfret, his Cimon and Iphigenia. See Walpole's *Anecdotes of Painting*.

LEMAN, or LAC LEMAN; the name of the former French department, comprehending the republic of Geneva, from Lemanus, the ancient name of the lake of Geneva.

LEMBERG, or LEOPOLIS (in Polish, *Lwow*); capital of the kingdom of Galicia, with 47,500 inhabitants, of whom 18,249 are Jews; next to Brody, the most important commercial place in the circle of the same name. It is the seat of the Austrian provincial government. Lon. 24° 2' 53" E.; lat. 49° 51' 42" N. Lemberg is the see of a Roman Catholic, a Greek Catholic, and an Armenian archbishop, and the seat of the Lutheran superintendent, and of the chief rabbi. It has a university, which was transferred to Cracow, but, in 1817, was re-established (with twenty-six professors and 220 students). There are several high schools, two theological seminaries, &c. The Ossolinsky library is public. Lemberg is eighty-eight leagues east of Cracow, is fortified, and carries on considerable trade.

LEMIERRE, ANTOINE MARIN; a French dramatist, born in 1733, at Paris. He received a good education, but, being deprived of his parents while young,

he became assistant sacristan to the church of St Paul. At his leisure, he composed sermons for sale in manuscript—a circumstance which made him known to the abbé D'Olivet, who employed him to correct the proofs of his edition of Cicero. He was then made an under master of rhetoric at the college of Harcourt, in which situation he wrote a tragedy, rejected at the theatre. He afterwards gained six poetical prizes, offered by provincial academies. His tragedy of *Hypermnestra* was acted with success in 1758. He subsequently obtained a place in the office of a farmer-general, who, perceiving that he was better qualified to make plays than to keep financial accounts, generously bestowed on him a pension, that he might be enabled to devote himself to literature. In 1781, he was chosen a member of the French academy; and he died in 1792. He produced several tragedies, among which the best and most successful were his *Widow of Malabar*, and *William Tell*: he also published *Les Fastes, ou les Usages de l'Année*, a poem in sixteen cantos; and a collection, entitled *Pièces fugitives* (1782, 8vo).

LEMMA, in mathematics, denotes a preliminary proposition, laid down in order to clear the way for some following demonstration, and prefixed either to theorems, in order to render their demonstration less perplexed and intricate, or to problems, to make their solution more easy and short.

LEMMING (*georgychus*, Illig.). These quadrupeds, which are of the rat kind, are distinguished by the conformation of the fore feet, and the shortness of the tail. The fore feet are adapted for burrowing. The tail is shorter than the body. Among the species, the most interesting are the lemming rat (*G. lemmus*) and the Hudson's bay lemming (*G. Hudsonius*). The former of these inhabits the northern parts of Europe, is about the size of the common rat, of tawny colour variegated with black, the sides of the head and the under parts being white. The legs and tail are grayish, and the under parts of the body of a dull white. The head is large, short, and thick; the eyes small; the limbs stout. They feed entirely on vegetables. They form shallow burrows, in summer time, under the ground, and, in winter, make long passages under the snow in search of food. The most extraordinary characteristic of these animals is their migrations, which they undertake at irregular epochs, seeming to be guided by the severity of the approaching winter. In these migrations, they assemble in incredible numbers, and always march in a straight line, nothing seeming to turn them aside. If they are disturbed whilst swimming over a lake or river, they will not recede, but swim on, and soon re-assume their former order. They chiefly move at night, or early in the morning, and make such a destruction among the herbage, that the surface of the ground over which they have passed appears denuded. Exposed as they are to every attack, and destroyed in attempting to cross rivers and lakes, the diminution of their numbers is very great, so that few return to their native haunts. They never enter dwellings, but keep in the open air. When enraged, they raise themselves on their hind feet, and utter a barking sound. Sometimes they divide into two parties, and attack each other. They breed several times in the year, producing five or six at a birth. Their numbers are so great in particular years, that the common people, in Norway, believe that they descend from the clouds. From the devastations which they commit, they are often exorcised by the Roman Catholic clergy.\* Their flesh is not used as food, nor the skins for the fur.

The Hudson's bay lemming is of an ash colour,

\* The following is the form of the exorcism used:—"Ex-

with a tinge of tawny on the back, having a dusky stripe along its middle, and a pale line on each side. The hair is very fine, soft, and long. It is not certain that these animals migrate like the foregoing species, though, from the observations of captain Lyon, this appears probable. He says that he observed long ridges of mouse dung, several inches deep, extending for above two miles. This was in a situation in which none of these animals were then found, and in a kind of soil in which they do not live. Hearne thinks that, from appearances, they seldom stray from their habitations, even in summer, and in winter, are rarely seen on the surface of the snow. This writer, however, may have only had an opportunity of observing them during those years in which they are stationary. They were first described by Forster, from a mutilated specimen, and afterwards, in a fuller manner, by Pallas. Doctor Richardson (*Fauna Am. Borealis*) is of opinion that this lemming is only found in the vicinity of the sea. It occurs in Labrador, and all parts of Northern America bordering on the Polar sea. It is said to be very inoffensive, and so easily tamed that, if caught, even when full grown, it will become perfectly reconciled to its situation in a day or two, very fond of being handled, and will creep, of its own accord, into its master's bosom.

LEMNOS (now *Stalimene*), the most northerly island of the Grecian Archipelago (the Ægean sea), between the Hellespont and mount Athos (147 square miles, 8000 inhabitants), abounds in vines, wheat, &c. It formerly contained a volcano, *Meschia*, which was regarded as the workshop of Vulcan. Mythology assigns this island as the residence of Vulcan (whence he is called *Lemnius*), after Jupiter had hurled him from Olympus. Various atrocities, perpetrated on this island (see *Hysipyle*), gave occasion, in antiquity, to the use of the epithet *Lemnian*, to designate such acts. Among its curiosities are a labyrinth, and the Lemnian earth (*terra sigillata*).

LEMOINE, FRANCIS, an historical painter, born at Paris, in 1688, was placed, in his thirteenth year, with the painter Galloche, with whom he remained twelve years, during which time he paid particular attention to the works of Carlo Maratti and Pietro di Cortona. In 1718, he became member of the academy. The war of the Spanish succession preventing the support of young artists at Rome, by the French government, he was obliged to defer the accomplishment of his wish to visit Italy till a rich amateur, of the name of Bergier, took him for his companion, in 1723; but a residence of six months in Italy, at a time when his talents were already developed, could not be so useful to him as the earlier study of the treasures of Roman art might have been. He finished, however, one of his best paintings, a female entering the bath, during his residence in Bologna, Venice, and Rome. On his return, he was appointed professor at the academy, and soon found an opportunity of displaying his talents in painting the chapel of the Holy Virgin in the church of Sulpice, the subject of which is the ascension. The composition of the picture, however, has some fundamental faults. It was restored by Callet in 1780, and cannot therefore be now considered as Lemoine's work. Lemoine subsequently painted the ceiling in

the hall of Hercules at Versailles, the largest painting in Europe, being sixty-four feet long and fifty-four broad, without being divided by any architectural interruptions. It contains 142 figures. He had almost finished the work, when he observed that the main group was placed a little too low, and he did not hesitate to raise it, although alterations were rendered necessary in almost all the other figures. His exertions in this work, which cost him the labor of seven years, weakened his health. His domestic misfortunes augmented the natural gloom of his disposition, and his chagrin at the marks of favor conferred on inferior artists combined with these circumstances to unsettle his reason. In a fit of insanity, he put an end to his life, in 1737. On an unprejudiced estimate of his labours, it cannot be denied, that the decline of the French school is principally owing to him. His drawing is accurate, his forms are disfigured by mannerism, but his colouring is brilliant, though wanting in truth, and his grouping is skilful.

LEMON. The lemon-tree (*citrus limonum*), originally brought from the tropical parts of Asia, but is now cultivated very extensively in the west of Europe, especially in Sicily, and the fruit is an important article of commerce. It is compared with the orange and citron, and belongs to the same family *aurantiaceae*. Its stature is that of a large shrub or small tree; the leaves are oval, pointed twice as long as broad, and, like those of the other species, contain scattered glands which are filled with a volatile oil. The beauty of its smooth evergreen foliage, and the delightful fragrance of the flower and fruit, have made it a great favourite in all our green-houses. The shape of the fruit is oblong, but its internal structure does not differ from that of an orange. The juice is acid and agreeable, mixed with water and sugar, it forms the well-known refreshing drink called *lemonade*, which is in general use throughout all parts of the civilized world. Lemon juice is also employed by calico printers to discharge colours. See *Citron*.

LEMONADE; a drink made of water, sugar, and the juice of lemons. Prepared in this simple way it is a very grateful beverage in warm weather, or for feverish patients. The taste is more agreeable, if the sugar is rubbed with the peel of the lemon, so as to imbibe the oil contained therein; but the lemonade is thus rendered stimulant rather than cooling, and many persons suffer from head-ache as a consequence. In public houses, cream of tartar is frequently used instead of lemon-juice, which persons can endure without feeling some head-ache. Lemonade was first sold publicly between 1630 and 1633, in Italy, and soon became very common. See *Limonade*.

LEMONTEY, PETER EDWARD, member of the French academy, jurist and poet, was born at Lyons in 1762, and died at Paris, June 27, 1825. At the convocation of the estates in 1789, he contributed to his essay—whether a Protestant can vote in the Election of the Members of the Estates, or be chosen a Member himself—to the restoration of the Protestants, who formed a numerous class of citizens, to their civil rights. Subsequently appointed deputy from the department of the Rhone, he joined the constitutional-monarchical party, and exerted himself to moderate the extravagant measures of the revolutionary demagogues. He succeeded in moving a great number of absent scholars, artists, and refugees from being confounded, in the laws against emigrants, with those who had left their country with no purpose of introducing foreign arms on their native soil. In the deliberations on the fate of Louis XVI., he conducted himself with equal humanity and

arcibus vos prestiferos mures per Deum Patrem omnipotentem, et Jesum Christum filium ejus, et Spiritum Sanctum, et ab utroque procedentem, ut confestim recedatis ab his compis, seu vineis vel aquis, nec amplius in eis habitetis, sed ad ea loca transeatis, in quibus nemini nocere possitis, et ex parte omnipotentis Dei, et totius curie celestis, et ecclesie sancte Dei, vos maledicatis, quocunque iteritis, sitis maledicti, defunctos de die in diem in vos ipsoe, et decrecentes quatenus reliquie de vobis nullo in loco inveniantur, nisi necessarium ad salutem et usum humanum, quod præstare dignetur ille, qui venturum et judicare vivos et mortuos ad seculum per ignem. Amen.

couage. During the reign of terror, Lemontey fled to Switzerland, whence he did not return till after the overthrow of the Mountain party. Deeply affected with the calamity which had involved his native city in ruin (see *Lyons*), he published his beautiful ode *Les Ruines de Lyons*. He afterwards travelled through Italy, published several poetical works in Paris, and wrote various operas and romances. In 1804, the government conferred on him, and two other literary men, the censorship of theatrical works—an ungrateful office, which he at first exercised with much discretion, but in which he subsequently exposed himself to the complaints of authors. After the restoration, he received the order of the legion of honour, and the office of the director-general of the book trade. He also succeeded Morellet in the academy. His romance *La Famille de Jura ou ironie-nous à Paris ?* (written on occasion of Napoleon's accession to the throne), in four months passed through as many editions. His *Essai sur l'Etablissement monarchique de Louis XIV.* (his master-work, bold and true) was an introduction to his unfinished *Histoire de la France depuis la Mort de Louis XIV.* Of his operas, *Palma, ou le Voyage en Grèce*, was very successful during the revolution, because he boldly attacked in it the Vandalism of those times—the destruction of the French monuments of art, under the name of *civism*.

LEMPRIERE, JOHN, D. D., a native of Jersey, was graduated at Oxford as A. M., in 1792. In the same year, he became head-master of Abingdon grammar-school, and afterwards master of the free grammar-school at Exeter. In 1811, he was presented to the rectory of Meeth, Devonshire, which living, together with that of Newton Petrock, in the same county, he held till his death. Doctor Lempriere was an excellent classical scholar, and published a *Bibliotheca classica* as an assistant in the study of antiquities and mythology. His other writings are the first volume of a translation of Herodotus, with notes, which appeared in 1792: an entire and elegant translation of that historian being given to the world by Mr Beloe, doctor Lempriere desisted from prosecuting his design. A compilation of *Universal Biography*, first printed in quarto, with an abridgment of the same, in octavo, both in 1808, was his last work. He died of apoplexy, Feb. 1, 1824.

LEMUR. This genus of the monkey tribe (the *makis* of Cuvier) has been divided into several subgenera; as, *Lemur*, which is distinguished by having six projecting incisors in the lower jaw and four straight ones in the upper. These animals have long tails, and take the place of apes in the island of Madagascar, none of the latter being found there. *Indris*, having four incisors below and the same number above; no tail; only one species known, which the inhabitants of Madagascar tame and train to the chase, like dogs. *Loris*, four incisors below, and four above; no tail. Their molar teeth have sharp points instead of tubercles, and they sometimes feed on small birds and quadrupeds. *Galago*, having six incisors below and four above; tail long and tufted; elongated tarsi to the hind feet, which render them very disproportionate to the superior extremities. *Tarsius*, four incisors above, two below, and several canine teeth between the incisors and molars; tail long, tufted. All these animals have their thumbs strongly developed, and the first finger on the hinder feet furnished with a pointed and elevated nail, all those on the other fingers being flat. Their hair is woolly.

LEMURES (*manes*, *lamiae*, ghosts, spectres), among the ancient Romans; the souls of the dead, which tormented men in the night, whence they were called *nocturnal* or *black*. In order to lay

them, a ceremony called *lemuria*, *lemuralia*, *remuria*, was observed on the nights of the 9th, 11th, and 13th May. About midnight, when every body was asleep, the head of the family rose, and went, barefooted, softly, and in silence, to a fountain. With a snap of the fingers, still keeping silent, he protected himself from the spectres. Having washed his hands at the fountain, he returned, took some black beans in his mouth, and, without looking around, threw them nine times over his head, repeating, each time, *Hæc ego mitto; his fabis me meosque redimo* (These I send; with these beans I redeem me and mine). He then washed his hands again, struck a hollow copper vessel, saying nine times during the operation, in a supplicating tone, *Manes, exite, paterni* (Ye souls of my ancestors, depart). He now looked around, and the ceremony was finished. It was believed that the spirits came and collected the beans.

LENA; a large river of Asiatic Russia, which rises in the mountains near lake Baikal, and empties, after a course of about 2000 miles, through four arms, into the Northern ocean, after having received the Wilime, Olekma, Aldane, and Wilhoul. It forms, at its mouth, a large bay, of the same name, containing many islands, called the *archipelago of the Lena*, which are cold and barren, but inhabited by many animals valuable for their furs.

LENCLOS, ANNE, called *Ninon de*, the French Aspasia, was born at Paris, in 1616, of noble parents. The early death of her parents having left her to follow her inclinations, her character was formed by the bent of her own feelings, and by the study of the works of Montaigne and Charron. Even at an early age, she was distinguished for her wit and acuteness. She played the harpsichord and several other instruments in a masterly style, sang with taste, and danced with grace. With such attractions she had no want of lovers and suitors; but her love of independence prevented her from forming a serious connexion. To render herself entirely free, she invested her property in an annuity, on which she lived frugally, but in good style. Her income amounted to 8000 or 10,000 livres. Without making a traffic of her charms, she attached herself to those who pleased her, as long as her inclination continued. Inconstant in love, but true in friendship, equitable in her temper, charming in her conversation, capable of forming young men, but also of seducing them, sensible, without making a display of her powers, handsome even in old age, she wanted nothing but female virtue, yet she conducted herself with dignity. She never accepted presents in return for her favours, though she gave herself up, from blind sensuality, to transient passion, without concerning herself whether its object was worthy of her. Having extended her favours, in succession, to the most celebrated men of her time, she proved to all, that mere sensual desire, and not vanity, was the cause of her passion. Notwithstanding her reputation for gallantry, the most amiable and respectable ladies of the time, such as La Fayette, La Sablière, and Maintenon, cultivated her friendship. Of madame de Maintenon she used to say, that she wished to employ her to drive away the tedium of rank and age at Versailles. Even in her old age, her house was the rendezvous of the most agreeable personages of the city and court, and of the most distinguished men. Scarron consulted her on his romances, St Evremont on his poems, Molière on his comedies, Fontenelle on his dialogues, and La Rochefoucault on his maxims. Coligny, Condé, Sévigné, &c., were her lovers and friends. When the queen of Sweden was in Paris, she paid Ninon a visit. Voltaire speaks of her as having lost her charms of person in extreme old age. St Evremont maintains the contrary. At her death, Oct. 17, 1705, she

bequeathed to Voltaire, then a young man, whose renown she had foreseen, a considerable sum, which he was to expend in books. One of Ninon's sons, named La Boissière, died, in 1732, at Toulon, an officer in the navy. His birth was distinguished by a dispute between an officer and clergyman respecting the paternity. As the matter was doubtful, it was decided by lot, and the officer obtained the paternal title. Ninon's second son died a tragic death. He had fallen in love with his own mother, without knowing his relationship to her. She was obliged to reveal the secret to him, to escape his importunities, and he killed himself from despair. This terrible event has been introduced, by Le Sage, into his *Gil Blas*. Ninon, moreover, confessed herself, that she was not happy, and often said, that, if she had foreseen her course of life, she would rather have undergone a voluntary death, than have submitted to such a destiny. The *Lettres de N. de Lenclos au Marquis de Saligny* are the work of Damours, the author of the life prefixed to the collection. The *Correspondence secrète de, &c.*, edited by Ségur (1789), is also a supposititious work.

LENNI LENAPE. See *Indians*, and *Indian Languages*.

LENOTRE, ANDREW; a French architect and ornamental gardener. He was born at Paris, in 1613, and was the son of the superintendent of the gardens of the Tuileries, who, wishing to make him an artist, placed him, as a pupil, with Vouet, the painter. He showed a strong taste for design, particularly in laying out gardens, and arranging their scenery. He first displayed his talents at the chateau de Vaux; but his plans for the decoration of the park of Versailles contributed principally to establish his reputation. He afterwards embellished the gardens of Clugny, Chantilly, St Cloud, Sceaux, the Tuileries, &c. Louis XIV. richly rewarded the labours of Lenotre, and, in 1675, bestowed on him letters of nobility, and the cross of the order of St Michael. He took a journey to Italy in 1678; and, at Rome, he was honourably received by pope Innocent XI. He died, at Paris, in 1700. Delille has celebrated the talents of Lenotre, whose style of ornamental planting was fashionable, not only in France, but in Britain, till it was superseded by the designs of Kent, Brown, and the modern landscape gardeners.

LENS, in dioptrics, properly signifies a small, roundish glass, of the figure of a lentil, but is extended to any optic glass, not very thick, which either collects the rays of light into a point, in their passage through it, or makes them diverge, according to the laws of refraction. Lenses have various figures, that is, are terminated by various surfaces, from which they acquire various names. Some are plane on one side, and convex on the other; others convex on both sides, both of which are ordinarily called *convex lenses*, though, where we speak accurately, the former is called *plano-convex*. Again, some are plane on one side, and concave on the other; and others are concave on both sides; which are both usually ranked among the concave lenses; though, when distinguished, the former is called a *plano-concave*. Others, again, are concave on one side, and convex on the other, which have the name *meniscus*. In every lens, terminated in any of the fore-mentioned manners, a right line, perpendicular to the two surfaces, is called the *axis of the lens*, which axis, when both surfaces are spherical, passes through both their centres; but if one of them be plane, it falls perpendicularly upon that, and goes through the centre of the other. See *Optics*.

LENT, a Teutonic word; in German, *Lenz* (the spring); in Swiss, *Glens*; in Dutch, *Lent*. Several derivations of the word have been proposed. Adelung

thinks that it is probably connected with the German verb *leinen* (to thaw). In English, *Lent* means the quadragesimal fast in spring, which, in Italian, is called *quaresime*; in French, *carême*, from the Latin *quadragesima*. In the article *Fasts*, the subject of fasting, in general, and the fasts and days of abstinence observed by the Roman church have been treated of. Lent is a fast intended to prepare Christians for the Easter festival. Protestants generally consider Lent not to have been established before the second or third century; but the Catholic church maintains, with St Jerome, St Leo, St Augustine, &c. the majority of the fathers of the church of the fourth and fifth centuries, that it is of apostolic origin. They reason thus: that which we find universally established in the church, and of which we cannot, nevertheless, find the institution by a council, must have been established by the apostles; and the sixty-ninth apostolical canon, the council of Jerusalem, 325, that of Laodicea in 365, and the fathers of the second and third centuries, speak of Lent as a fast generally observed by the church. In the Latin church, Lent formerly lasted but thirty-six days, & the fifth century, four days were added, in memory of the forty days' fast of the Saviour, and this became general in the Western church, except in the church of Milan. (See *Dictionnaire de Théologie*, article *Carême*.) The Greeks begin Lent one week sooner than the Roman Catholics, but they do not fast on Sundays, except in passion-week, though the fasts, generally speaking, are much more strict than those of the Roman Catholics. The Latins maintain formerly three fasts, of forty days each, and the Greeks observed four besides Lent; but they have reduced them to seven days each. Some Oriental sects had still other great fasts. The eighth canon of Toledo, in 653, orders that those who break the fast, without necessity, shall eat no meat during the whole year, and shall not partake of the Lord's supper at Easter. The bishop must give the sick an aged permission to eat animal food during Lent. Such permissions are, however, generally put into the hands of physicians, from whom it is not difficult to obtain them. Until the year 1800, but one meal a day was eaten during Lent. The close of Lent is celebrated in Catholic countries with great rejoicing. In Rome, the *pizzicoretti*, or shops in which hams, sausages, eggs, &c., are sold, are illuminated and ornamented, in the most picturesque manner, the night before, in order to attract buyers. The statue of a saint, made of butter, is often seen. Hams & eggs are multiplied endlessly by reflecting mirrors, and the whole scene is quite brilliant and amusing. Milk is allowed during Lent. The English church has retained Lent, and many other fasts, but gives no directions respecting abstinence from food. See *Carnival*.\*

LENTIL; a species of *erum*. The common lentil comes from France and the Valais. The stem annual root brings forth weak, creeping, hairy, angular stalks, from one to two feet long, divided, from the bottom, into several branches, and clasping for support to other plants; the pinnate leaves stand alternately; from the axils of the leaves proceed the stalks, which each have two or three whitish flowers hanging down. The pods do not contain more than two sound seeds, flat upon both sides. Lentils are

\* Though Lent is established to subdue our carnal appetites, and to induce us to live more spiritually, the following remark is found in the Catholic work quoted above: "If the rich would add also to the fast on the above prescribed, the poor would live better, and more comfortably during Lent, than in any other season of the year, and would bless God for this salutary institution." — p. 116, in *L. Dic. de Théologie*, Toulouse, 1817.

cultivated for the seeds just mentioned. They require a rather sandy, yet strong soil; they are sown somewhat later than peas and vetches, because they cannot endure night frosts; they are to be sowed in drills, and well harrowed. Care is to be taken that the seed is not put too deep into the ground, and that the young plants are well hoed and well weeded. For the harvest, the time is to be chosen when the little pods begin to turn brown, though the plant may be still quite green; and, if possible, it is best to choose the afternoon of a dry, warm day; for if the pods are quite ripe, or are wet with rain at the time of gathering, they easily crack open, and a great loss of seed takes place. Two varieties are cultivated—the large *garden lentil*, and the common *field lentil*. The former is distinguished by its size, and the greater quantity of mealy substance which it will afford. The straw of lentils is good food for cattle and sheep, particularly for calves and lambs. Lentils are also mixed with vetches, and sowed as food, both green and dried, for milch kine. Lentils, when cooked, afford a nutritious food (this should be done in the pod, to preserve their flavour), but, like peas and beans, are not good for persons whose digestive powers are weak, particularly if they are not cooked quite soft. They ought to be boiled for two hours and a half. When they are browned, some butter, and a few onions roasted in butter, are added, also salt; they are then boiled half an hour more. A good soup may also be made of them. Some persons soften the lentils, before cooking, in cold water. Purified rain water is best to cook them in. In the Archipelago, they are one of the principal articles of food. To fatten pigs, lentils are excellent, and, given with other food, increase the milk of cows.

LENTO (*Italian*, slow); a term used in music.

LENTULUS; the name of one of the most illustrious families in Rome, several individuals of which distinguished themselves by their virtues and services; others were conspicuous in other ways. Publius Lentulus Sura, an accomplice of Catiline, was strangled in prison. Lentulus Spinther, one of the most luxurious and ostentatious men of his age, was a partisan of Pompey. Having been pardoned by Cæsar, who had made him prisoner, he again joined the former, and was present at the battle of Pharsalia. Cneius Lentulus was put to death, in the reign of Caligula, in consequence of being detected in forming a conspiracy against that monster.

LEO I. (THE GREAT, ST) was born, according to some writers, in Rome, and, according to others, in Tuscany. The popes Celestine I. and Sixtus III. employed him in important ecclesiastical affairs, while he was only deacon. On the death of Sixtus III., in 440, Leo was elevated to the papal chair. The Romans were gratified with this choice; but the beginning of his pontificate was marked by an intolerant and impolitic act. He caused processes to be instituted against the Manicheans, who were concealed in Rome, and gave up those who persisted in their heresy to the secular arm. In the same manner, he proceeded against the Pelagians, Priscillianists, and Eutychians, whom he exterminated. During the session of the council of Chalcedon, in 451, to which Leo had sent four legates, Attila laid waste the Western empire, and threatened Rome. The emperor Valentinian employed Leo to intercede with that formidable warrior, in order to obtain peace. Leo addressed the barbarian with mildness, and, at the same time, with impressiveness; and Attila, induced probably, however, by other motives, left Italy, and retired beyond the Danube; but, in the year 455, the Vandal Genseric took Rome, which was exposed to pillage for fourteen days. All the favour that Leo could obtain from him was, to forbid the murder of

the citizens, the burning of the city, and the plunder of the three principal churches in Rome, which contained the rich offerings of Constantine. Leo is the first pope whose writings have been preserved. These writings consist of 96 sermons, 141 letters, and some other works. A work on the Calling of the Gentiles, and the Epistle to Demetriades, have also been ascribed to him. His style is finished and rhetorical, and his periods have a measured rhythm, which is not unpleasant. There have been several editions of his works; one by Quesnel, at Paris (1675, two vols., 4to); another at Lyons (1700, fol.); a third at Rome, by Cacciari (three vols., fol.); and a fourth at Venice (1757). Father Maimbourg has written his life.

LEO X. (GIOVANNI DE' MEDICI), second son of Lorenzo the Magnificent, born at Florence, in 1475, received the tonsure in his seventh year, and was loaded with benefices. The election of Innocent VIII. to the papal chair, favoured the ambitious views of his father, and, in 1488, Giovanni, then only thirteen years old, was made a cardinal. Lorenzo intrusted his education to the Greek Chalcondylas and the learned Angelo Poliziano. Giovanni, naturally grave, took a greater interest in the writings of the ancient philosophers than in those of the fathers of the church; it was, therefore, made a condition of his nomination, that, before he should be invested with the purple, he should study theology three years at Pisa. In 1492, Giovanni took his seat in Rome, as a member of the holy college. His father died soon after, and was succeeded by his son Pietro, at Florence. As the young cardinal had opposed the election of Alexander VI. to the papal see, he exchanged Rome for Florence, where he lived in high estimation, until the banishment of his family forced him to fly to Bologna. In 1499, he went to Venice, Germany, and France, remained some time in Genoa, and then returned to Rome, where he lived in the enjoyment of a select society, and devoted to the arts, particularly music and literature. In 1505, he first took part in public affairs. Pope Julius II. made him governor of Perugia, and, in 1511, placed him, with the title of *legate of Bologna*, at the head of his forces, in the holy league against France. As his suggestions, however, were little regarded by the Spanish generals of the allied armies, his influence was limited to preserving order in his camp. He was made prisoner by the French, at the battle of Ravenna, in 1512, but soon after regained his freedom, on the dispersion of the victorious army, and returned to Bologna, where he conducted the government as legate, and, after contributing to the re-establishment of the Medici, remained at Florence until the death of Julius II. recalled him to Rome. The choice very unexpectedly fell upon him, and he ascended the papal chair in 1513, in the thirty-eighth year of his age, under the name of *Leo X*. He immediately appointed two of the principal writers of his time, Bembo and Sadoleto, his secretaries. In foreign politics, he followed the system of his predecessors, opposing the domination of foreigners in Italy as much as possible. He succeeded in driving out the French, put an end to the divisions in the church, and forced Louis XII. to a formal submission. Having thus restored the public tranquillity, in the first year of his government, he gave all his attention to the promotion of literature and the arts, which had been neglected by his predecessors. The university at Rome was restored and endowed, privileges were granted it, and the most distinguished men selected as instructors. He also established a particular society for the publication of Greek authors, under the supervision of John Lascaris. That scholar, whom he had invited from Venice, and Marcus Musurus,

brought over a number of young linguists, whose influence assisted in promoting a taste for classical literature. He requested the possessors of ancient manuscripts, in all countries, to make them known to him; and the publication of the five first books of the *Annals of Tacitus*, was one of the finest fruits of his efforts. Several private individuals followed the example of the pope; among whom, Chigi, a merchant, was distinguished, who established a collection of works of art, and published an edition of Pindar and Theocritus. To prevent a union of Spain, France, and Austria, Leo favoured a reconciliation between the kings of England and France, and even pretended to favour Louis's plans on Milan. His design of obtaining the kingdom of Naples for one branch of his family, and the duchies of Ferrara and Urbino for other branches, made the friendship of this monarch necessary, and produced a secret alliance between them; but, when a French army appeared on the frontiers, he was not satisfied with increasing his power, by a purchase of Modena from the emperor Maximilian, but also sent Bembo to Venice, to detach the republic from the French alliance; in which, however, he did not succeed. This artful, varying policy was, at that time, universal, and Leo cannot be especially blamed for it. After the death of Louis XII., Francis I. having ascended the throne, and war appearing unavoidable, Leo, joined the alliance of the emperor, the king of Arragon, the states of Florence, Milan, and Switzerland; but, after the battle of Marignano, he withdrew, and, in 1515, he had an interview with Francis at Bologna, and formed with him a concordate, advantageous to both, but warmly censured by the French nation. In order to increase the power and splendour of his family, after the death of his brother Giuliano, he deposed the duke of Urbino, in 1516, and gave the duchy to his nephew Lorenzo. Leo saw with regret the reconciliation of the belligerent powers, which was effected in the same year. In 1517, the duke of Urbino, who had been deprived of his estates, recovered them by force of arms. Leo, however, collected a powerful army against him, and forced him to renounce his claims on honourable terms. In the same year, a conspiracy against the pope was discovered, and cardinal Petrucci, who was suspected of being the principal, was hanged, notwithstanding the passport which had been given him. Others, whose guilt was not sufficiently proved, were tortured, deprived of their dignities, and banished. The conduct of the pope, in this instance, was neither magnanimous nor merciful. Leo's magnificence had exhausted his finances. To procure money, particularly for the completion of St Peter's, he put all Christendom under contribution, by the sale of letters of indulgence. (q. v.) This abuse roused the zeal of Luther, and produced the reformation. Leo, at first paid little regard to the attacks of Luther, and when he could no longer keep silence, was inclined to lenient measures. In compliance with the wishes of Maximilian, he assumed more rigour, and summoned Luther to appear in Rome, but finally agreed that he should defend himself at Augsburg, before the cardinal Caietan. Nothing being decided by that measure, he issued, in Nov. 1518, the well-known bull, in which he defended the papal authority of dispensing indulgences, and threatened all, who maintained contrary doctrines, with excommunication; on which Luther appealed to a general council. While open war had thus broken out in the church, Leo endeavoured to unite all Christian monarchs in a crusade against the Turkish emperor Selim, who had made himself master of Egypt; but their mutual jealousies prevented the execution of his plan. Besides these public chagrins, Leo had great domestic misfortunes

to suffer. Lorenzo, who had connected himself with the French court by marriage, having died, and left only a daughter, Leo therefore annexed Urbino to the States of the Church, and the cardinal Guido de' Medici was placed in the government of Florence. Though, in Germany, the reformation continued to gain ground, Italy was not disturbed by foreign wars. This state of things permitted Leo to indulge his taste for splendour, to promote the arts and sciences, and, at the same time, to increase the power of his family. Although in alliance with France, he did not give up his plan of preventing the aggrandisement of that power in Italy. With this view, he united with the emperor, in 1521, for the re-establishment of the family of Sforza, in Milan, and took 30,000 troops into pay. The war was begun successfully. Parma and Piacenza were taken by the papal troops, and annexed to the States of the Church. The allies entered Milan without resistance, and occupied the territory of the duke of Ferrara, whom Leo had excommunicated as an ally of France. While engaged in celebrating his successes, Leo died suddenly, Dec. 1, 1521. The age of Leo is described in Roscoe's *Life and Pontificate of Leo X.* which has been translated into German, Italian, and French.

LEO XII., (ANNIBALE DELLA GREGGIA), born at Genoa, Aug. 2, 1760, became cardinal March 1, 1816, and succeeded Pius VII. in the papal chair, Sept. 28, 1823. He early served the interests of the Roman court as a nuncio in Switzerland, at Dresden, and at other German courts, went on an embassy to Louis XVIII. from pope Pius VII., and was finally created vicar-general of Rome. As pope, he made himself beloved by the people, by the remission of many taxes, by his benevolence, by personally inspecting the public institutions for the poor, the hospitals and the prisons. His firm maintenance of the rights of the court of Rome involved him in disputes with the French and Austrian governments in 1824. On Ascension-day, 1824, he announced the next year as the year of jubilee. His circular epistle to the nations of Christendom, on that occasion, contains a warm attack on Bible societies. May 1<sup>st</sup> 1824, he gave to the Jesuits and their general, Leo Fortis, the Roman college, which they had possessed until 1773, together with the church of the *Immaculate Conception*, the *oratorium*, the museum, the library and the observatory, in order that they might devote themselves entirely to the education of the young. Leo XII. also strengthened the connection of the apostolic see with the Spanish American republics, particularly with Chile, and, in 1823, with Colombia, by recognising Bolivar's bishops. He endeavoured to free the States of the Church from robbers and banditti, as well as to suppress the remains of Carbonarism. In 1825, he restored the prisons of the inquisition. His attention was particularly directed to the remedy of numerous abuses in the departments of the Roman government, for instance, in the *sancta apostolica*. Leo died in Feb. 1829, and was succeeded by cardinal Castiglione, who took the name of Pius VIII. Pius died Dec. 1830, and was succeeded by cardinal Cappellari (Gregory XVI.)

LEO VI. emperor of the East, surnamed the *Philosopher*, was the son of Basil I., whom he succeeded in 886. He reigned weakly, and the ill success of his generals against the Bulgarians, obliged him to submit to such terms of peace as those barbarians pleased to propose. A total defeat of his fleet by the Saracens, also took place a short time before his death, which happened in 911, after a reign of twenty-five years. He gave his name to several works, the principal of which are, a *Treatise on Taxes*, *Novella Constitutiones*; and *Opus Basilicum*, a collection of laws, begun by his father. He was

addressed a letter to the caliph Omar on the truth of Christianity.

LEO, LEONARDO, chapel-master in the Conservatorio St Onofrio, and private composer to the royal chapel at Naples, born in 1694 (according to Piccini, 1701), at Naples, probably studied under Scarlatti. To him, to Pergolesi, and some other composers of that period, is to be attributed the reputation which the Neapolitan school acquired all over Europe. Among his scholars, Piccini, Sacchini, Pergolesi, Traetta, are distinguished. He surpassed all his predecessors, and, as he became equally perfect in all the departments of composition, he may be esteemed one of the greatest masters of Italy. All his works were studied with veneration by the Italian musicians. Although Leo was very successful in passionate, grand, and elevated compositions, he was not less so in simple, tender, and comic, as his comic opera *Il ciccio* proves. Leo is, besides, the first composer who availed himself of the form of *rondos* in his comic operas. He died in 1742. His best operas are *Sofonisba* (1718, according to Burney, his first opera); *Olimpiade*; *La Clemenza di Tito* (1735); *Achille in Sciro* (1740). He composed two oratorios—*Santa Elena al Calvario* (to the words of Metastasio), and *La Morte d'Abele*. Of his church-music, his *Ave Maria*, and a *Miserere alla Capella*, are the most remarkable.

LEO, JOHN (surnamed *Africanus*), a traveller and geographer of the sixteenth century, was born of Moorish parents, at Grenada, in Spain, and, when that city was taken by the Spaniards, in 1492, retired to Africa. He studied at Fez, and afterwards travelled through various parts of the north of Africa. Having been captured by pirates, he was taken to Italy, and presented to pope Leo X., who persuaded him to embrace Christianity, and gave him his own name on his being baptized. At Rome, he acquired a knowledge of the Italian language, into which he translated his *Description of Africa*, originally written in Arabic. This is a very curious and interesting work, comprising accounts of several countries rarely visited by Europeans. Leo also composed a treatise on the lives of the Arabian philosophers. He is supposed to have died soon after 1526.

LEOBEN; a town on the Mur, in the Austrian duchy of Styria, about 1600 feet above the sea, with 2400 inhabitants, famous as the place where the preliminaries of the treaty of Campo-Formio were concluded, between Austria, Naples, and the French republic, August 17, 1797, after Bonaparte's successful campaign of 1796 in Italy, against the archduke Charles. (See *Campo-Formio*, *Peace of*.) Here the young French general displayed great talents as a statesman, deriving little aid from the instructions of the directory. See *Napoleon*, and *Italy*.

LEON, PONCE DE. See *Ponce de Leon*.

LEON; one of the great divisions of Spain, usually styled the *kingdom of Leon*; bounded north by Asturia, east by Old Castile, south by Estremadura, and west by Portugal and Galicia. It was united to Castile in the beginning of the eleventh century. The soil is generally fertile, and produces all the necessities of life; and the wine is tolerably good. Population, 1,215,551; square miles, 21,000. It is divided into six provinces.

LEON (anciently *Legio Septima Gemina*); a city of Spain, capital of a province to which it gives name, at the conflux of two rivers, whose united stream runs into the Esla, ten miles south of the town; 150 miles north-west Madrid; lon. 5° 37' W.; lat. 42° 45' N.; population, 5900. It is a bishop's see. This city is very ancient, and was formerly much more rich and populous than it now is. It was the capital of a kingdom of the same

name, and the kings resided in a palace here till the year 1037. It now contains thirteen parish churches, nine convents, and four hospitals. The cathedral is handsome, and abounds in relics. In it are seen the tombs of thirty-seven kings and one emperor.

LEONARDO DA VINCI. See *Vinci*.

LEONIDAS, king of Sparta, son of king Anaxandrides, ascended the throne 491 years B.C. When Xerxes, king of Persia, invaded Greece with an immense army, Athens and Sparta were the only great cities which resolved to resist him. The Spartans gave the chief command of the military force to Leonidas, who marched to Thermopylæ, in the year 480 B.C., with 300 men. Small as his army was, amounting to but 7000 men, including the allies, he stationed it so skillfully, that the Persians, on coming to the narrow pass, became aware of the difficulty of carrying it by force. Xerxes, therefore, attempted to bribe Leonidas, offering him the dominion of all Greece. This proposal being rejected with scorn, the despot sent a herald to order the Greeks to surrender their arms: "Let him come and take them," was the reply of the Spartan king. Thrice did the Persians advance against the pass, in great force; thrice were they repelled, with great loss. Meanwhile, a traitorous Greek, named Ephialtes, led a select troop of 10,000 Persians, by a secret path, over the mountain, who, after compelling the few opposing Phocians to take to flight, appeared in the rear of Leonidas. He now saw that all was lost, but resolved to show, by a memorable example, what the Greeks could perform in the cause of their country. He is said, also, to have been influenced by an oracle, which declared that Sparta could be saved only by the death of one of its kings. To avoid useless bloodshed, Leonidas dismissed the greater part of his troops, and retained but 300 Spartans, 700 Thespians, and 400 Thebans; the last, in some measure, as pledges of the fidelity of their countrymen, and the Thespians, because they could not be induced to leave their Spartan allies. As soon as Xerxes had learned the successful passage of the troops led by Ephialtes, he threw himself, with his whole force, into the entrance of the pass. But Leonidas, before daybreak, penetrated into the Persian camp. After a long contest, the hero fell, surrounded by fallen enemies. His men defended his body, till they sank beneath countless assailants. This defence of Thermopylæ is one of the most remarkable exploits of antiquity. The Greeks erected a splendid monument to the fallen, and celebrated, annually, warlike games over their sepulchres.

LEONINE VERSE; a kind of Latin verse, in vogue in the middle ages, consisting of hexameters and pentameters, of which the final and middle syllables rhyme; so called from Leonius, a poet of the twelfth century, who made use of it, or, according to some, from pope Leo I. (A.D. 680). Poems of considerable length were written in this barbarous taste. The following distich may serve as an example:

Dæmon languebat, monachus tunc esse volebat;  
Ast ubi convaleuit, mansit at ante fuit.

Leo versified a great part of the Old Testament in this manner. See *Rhyme*.

LEONTIUM (Leontia); a courtesan, the scholar and mistress of Epicurus. According to some, she was his lawful wife; according to others, the mistress of Metrodorus. She is said to have possessed distinguished talents, and to have composed an essay, replete with acuteness and learning, in a beautiful Attic style, in defence of the doctrines of Epicurus against Theophrastus.

LEONTODON TARAXACUM, or DANDELION; the name of a plant, indigenous to Europe,

but now also common in America. The leaves are all radical and runcinate, or jagged on the margin, and from this circumstance has been derived its French name—*dent de lion* or lion's tooth, of which the English appellation is a corruption. The stems are hollow, and bear single, large, yellow flowers, consisting of a congeries of florets, each of which is succeeded by a naked seed, bearing, on a long pedicle, a tuft of radiated down. By means of this tuft, the seed, when detached, is kept suspended in the air, and transported, by the winds, to a distance. In this respect, however, it does not differ from most of the *compositæ*. The whole plant is full of a milky and bitter juice; notwithstanding which, it is in common use as an early vegetable. The roots, when roasted, are said to form a good substitute for coffee, and are used for that purpose in some parts of Germany.

**LEOPARD** (*felis leopardus*). This beautiful but savage animal is spread as widely over the countries of the continent as the lion, and, throughout this extent, he varies but little, and that merely in magnitude, in the size and form of his markings, and the intensity of their colouring; but he is every where the same as to form and structure, as well as in character and disposition. His ground colour is a yellowish fawn, which becomes paler on the sides, and is lost in the pure white of the under part of the body. The back, head, neck, limbs, and under surface of the body, are marked with black spots, of different sizes, and placed in an irregular manner, whilst the sides are covered by numerous distinct roses, formed by the congregation of smaller spots, placed in a circular form. In general appearance, this animal is fierce, and is, in fact, equally savage and dastardly with the rest of the cat kind. His usual prey is antelopes, monkeys, and the smaller quadrupeds. He always avoids man, except when closely pursued, when he offers an obstinate resistance. Occasionally, however, the lone traveller has fallen a victim to these ferocious and sanguinary animals. When they attack a flock of sheep, the slaughter they commit is almost incredible. Kolbe states that two leopards, a male and female, and three young ones, entered a sheepfold at the cape of Good Hope; the old animals killed nearly a hundred sheep; when they were satiated, they fed their young, and, each seizing a whole carcass, attempted to move off, but they were waylaid, and killed. The Negroes take them in pitfalls, slightly covered over with hurdles, on which a piece of meat is placed as a bait. From the extraordinary flexibility of the limbs of this animal, he is enabled to ascend trees, in which he usually takes refuge when pursued. When taken young, he can be tamed to a certain degree. According to travellers in Africa, the flesh of the leopard is excellent, resembling veal. The skins are valuable, selling, in Europe, at from £5 to £10.

*Hunting-leopard* (*F. jubata*), or *cheetah*, as it is termed in India, is about the size of a greyhound, with a narrow chest and long legs, of a thin make in the body and limbs, apparently calculated rather for speed than strength. In fact, this animal forms a sort of connecting link between the feline and canine groups. He is of a pale yellow colour on the upper part, white underneath, and covered all over with very small irregular spots. He has a slight mane, extending along the back of the neck and upper part of the back. He is capable of being perfectly tamed, and is employed, in the East, for the chase of antelopes. He is carried to the field in a cart, in which he is kept chained and hoodwinked, till brought within view of a herd, when he is released, and the hoods removed. The animal steals gradually towards his prey, till he has attained a proper

distance, when, with five or six surprising bounds, he springs upon it. If, however, he is unsuccessful in his attack, he does not attempt to renew it, but returns with a mortified air, to his keeper.

**LEOPOLD I.**, German emperor, second son of the emperor Ferdinand III. and Mary Anne of Spain, born 1640, was chosen, in 1655, king of Hungary; in 1658, king of Bohemia; and, in 1689, emperor of Germany. On ascending the throne, he was obliged to promise to afford Spain no assistance against France. The Turks had then defeated the imperial army, and desolated Moravia, because the emperor had aided the prince of Transylvania, Ragotsky, who had ceased to pay an annual tribute to the Ottoman Porte. Montecuculi, Leopold's general, supported by 6000 select French troops, under Coligny and Feuilleade, defeated the Turks, August 1, at St Gothard; but, instead of improving this victory, the cabinet of Vienna concluded a truce for twenty years, and Ragotsky remained tributary to the Porte. Hungary was to be totally subjugated, but the nobles of this country attempted to throw off the Austrian supremacy, and to choose a king from their own nation. This undertaking cost Zriny, Frangepani, Nadasti, and other Hungarians, their lives. Tekeli (see *Tekeli*) now placed himself at the head of the malcontents, and was chosen king of Hungary by the Turks, for an annual tribute of 40,000 sechins. Tekeli called the Turks into the German empire; with an army of 200,000 men, they captured the island of Schutt, and laid siege to Vienna, in 1683. Just as the city was on the point of surrendering, John Sobiesky hastened to its relief. The Turks were attacked in their intrenchments, and suffered a total defeat. A panic terror seized the grand vizier, Kara Mustapha; he fled, and left the camp to the victor. This defeat was followed by others, and the imperialists recovered all the lost cities. Leopold caused the Hungarian insurrection, whom he looked upon as the cause of all the dangers which menaced Germany, to be severely punished. Hungary, which had been an elective monarchy, was declared, at the diet of Presburg, in 1687, hereditary in the Austrian male line, and Joseph, the eldest son of the emperor, was crowned as king of Hungary, without any previous election. Transylvania submitted, without reserve, to the Austrian house. Leopold waged three wars with France, which he declared wars of the empire. The first, in 1672, in connexion with Spain and Brandenburg, to assist the Dutch, attacked by the French and British, was unsuccessful on the part of the emperor and empire, and was terminated by the peace of Nimeguen, February 3, 1679. The second war had its origin in the league formed at Augsburg, in 1686, with Holland and Spain against France. In this war, the Palatinate was terribly devastated by the French. The German arms were generally successful, and, by the peace of Ryswick, October 30, 1697, France restored all that it had torn from Germany since 1680, besides relinquishing to Germany, Breuck, Friburg, Kehl, Philipsburg, and several smaller fortresses. The duke of Lorraine, a near relation of the king, recovered his territories, from which his family had been expelled, in 1670, by Louis XIV. The third war was undertaken by Leopold, in 1702, in order to procure the succession to the throne of Spain for his second son, Charles; but he died in the course of this war, May 5, 1705. His eldest son, Joseph, already crowned Roman king, in 1686, prosecuted the war with great vigour. (Respecting the great commotions in Hungary, in the beginning of the eighteenth century, see *Ragotsky*.) As the youngest son of Ferdinand III., Leopold had been educated for the church, and his reign was marked

by attachment to the clergy, irresolution, and indulgence towards his ministers, to whom he intrusted the whole management of the government. He was passionately fond of music, and was himself a composer. After he had uttered his last prayer, on his death-bed, he caused his musicians to enter, and departed to the sound of instruments. He was thrice married. Two sons survived him—Joseph I., born in 1678, his successor, and Charles, archduke of Austria, born 1685, who became emperor in 1711.

LEOPOLD II., emperor of Germany, born 1747, on the death of his father, the emperor Francis I. (1765), became grand duke of Tuscany, and, during a reign of twenty-five years, almost regenerated that country. He encouraged commerce, agriculture, and manufactures, improved the roads, established penitentiaries, abolished the inquisition, and proclaimed a new criminal code. His financial administration was admirable, and he was personally simple in his manner of living. He preceded his brother Joseph (q. v.), emperor of Germany, in measures of ecclesiastical reform, but conducted them with more prudence and caution, yet to the great displeasure of the Roman court. When the death of Joseph II. called him to the imperial throne, he found the hereditary states of Austria in a critical situation. In pursuance of the terms of the convention of Reichenbach with Prussia (July 27, 1790), he concluded an armistice with Turkey, which was followed by the peace of Sistova, in 1791, surrendering all the Austrian conquests to the Porte. After reducing the revolted Netherlands, by force of arms, he allowed them the enjoyment of their former privileges, and restored many of the ecclesiastical establishments, which had been abolished by Joseph. Quiet was restored in Hungary, the police and the administration of justice were reformed, and public education encouraged. In 1791, he had the celebrated interview with the king of Prussia, at Pilnitz, on which occasion the two monarchs declared the situation of the king of France to be a subject of general interest to all the sovereigns of Europe. After having restored many institutions and usages, which Joseph's ardent spirit had led him to abolish, Leopold died, March 1, 1792. Leopold was one of the best disposed monarchs who ever sat on a throne, and it is not to be denied that he effected much good; but it was his lot to reign at the time of a great struggle between old and new principles, which is always a difficult, and generally a deplorable situation for a prince, who is plunged into a whirlpool, where all power of self-direction is lost. This should be kept in mind, in judging of the convention of Reichenbach.

LEOPOLD I., prince of Dessau, a Prussian general, born in 1676, early showed a strong inclination for the military service, and, in his twelfth year, received from the emperor Leopold the command of a regiment. After having travelled two years, he made his first campaign on the Rhine, in 1696. In the war of the Spanish succession, he proved himself brave and skilful general. He had an honourable share in the victory at Blenheim, and fought with distinction in Italy. After having commanded the Russians in the Netherlands, he was made general-field-marshal in 1712, and Frederic William I., the new king, was so much attached to him, that he kept him constantly near his person. In a campaign against the Swedes, he was again victorious. Frederic the Great placed no less confidence in him, and in 1742, he received the chief command in Silesia. In 1745, he gained the bloody battle of Kesseldorf, the consequence of which Dresden was taken by the Russians, and peace was concluded. When not in the field, he paid great attention to agriculture. He

died of apoplexy, in 1747. At the time of his death, he was imperial and Prussian general-field-marshal, and governor of Magdeburg. His manners were rough, often coarse; but he was brave, sincere and honest, and very much beloved by the soldiers. A popular march, still often played in Germany, particularly in the North, is called the *Dessauer March*, because it was prince Leopold's favourite.\*

LEPANTO, or AINABACHTI; formerly a sangiac, in Rumili (Turkey), with 80,000 inhabitants. The capital of the same name, a seaport, was anciently called *Naupactus*; lon. 22° 20' E.; lat. 38° 27' N.; population, 2000, according to Hassel. The town is situated in a bay, formerly called the *gulf of Corinth*, now the *gulf of Lepanto*, or *gulf of Patras*, which is seventy miles long. It is fortified and defended with a castle built on an eminence. Being ceded by the emperor to the Venetians, it was fortified by them, and, in the year 1475, stood a siege of four months against the Turks, who lost 30,000 men. Near this town, don John of Austria obtained a celebrated victory over the Turkish fleet, Oct. 7, 1571. Cervantes, the celebrated author of *Don Quixote*, fought as a soldier in this battle, and had his left hand shot off by an arquebuse. The Turkish fleet consisted of 210 galleys, 23 transports, and 6 galleasses, with heavy artillery. The Spanish fleet was increased by an auxiliary flotilla, sent by the Venetians, and by some papal galleys. Both the fleets sought to come to close quarters. The battle was fought with bows, javelins, grappnels, and with cannon, muskets, pikes, and the sword. John of Austria, the commander-in-chief, and Veniero, the commander of the Venetian squadron, attacked the Turkish admiral Ali, took his vessel, and made him prisoner. His head was immediately struck off, and placed above the top of his own flag. The Christians were victorious. The Turks lost 150 vessels; more than 15,000 men were killed, and 5000 Christian slaves liberated. The Christians also lost 5000 men slain and wounded. Nothing prevented their sailing to Constantinople, except a dispute in regard to the division of the booty. This battle put a stop at once to the progress of the Turkish power, which had attained a fearful magnitude in the Mediterranean. (See *Barbarossa*.) The Christians had almost lost the hope of effectually resisting it; and, for this victory, don John of Austria (q. v.) deserves the gratitude of the whole European world.

LEPER. See *Leprosy*.

LEPIDUS, M. EMILIUS, the Roman triumvir, having served the interests of Cæsar, was made by him his colleague in the consulship. After the assassination of Cæsar, although the republican party endeavoured to win him to their ranks, he joined Antony, and afterwards made the infamous partition of the empire with him and Octavius Cæsar. (See *Augustus*.) After the victory of Philippi, his two colleagues made a new division, leaving him, however, the command of Africa. Augustus having called him to render assistance against Sextus, Lepidus attempted to render himself master of Sicily, but was obliged to submit to the former, and to take his seat again in the senate. Montesquieu says that he was the worst citizen in the republic. Without firmness or talents, he seems to have been elevated by fortune to render his fall the more striking.

LEPROSY (Greek *λεπρος*); a name given to several

\* It is related of Prince Leopold, that he used to pray, before battle, to the following effect: "O God! assist our side; at least, avoid assisting the enemy, and leave the result to me." This, if not true, shows, at least, the opinion entertained of his simplicity and straight-forwardness, and must be allowed to agree entirely with his character.

different diseases. The elephantiasis is sometimes called *leprosy of the Arabs*. The *leprosy of the Jews* is distinguished by white, cutaneous spots, composed of smaller spots, which appear sometimes in one place and sometimes in another, and are covered with a rough scaly matter. It appears to have been the *λεπροσ* of the Greek writers. The *Greek leprosy* is characterised by hard, insensible tubercles, which appear upon the skin, and are accompanied by a progressive insensibility, and the loss of the voice. It is endemic in Egypt, Java, and some parts of Norway and Sweden. The use of unhealthy articles of food seems to be one of its causes. It is hereditary and contagious. It was introduced into Western Europe in the time of the crusades, but has gradually disappeared. The tubercles which characterise leprosy appear in different parts of the skin: they are hard, rough and numerous, and cause the loss of the hair at the places where they appear. They finally terminate in ulcers, which penetrate even to the bone, producing a caries. They also cause the separation of parts of the body, the toes and fingers, for example, dropping off. These symptoms are accompanied with a languor in the motions, a dulness of the senses, a change of the voice, offensive breath, and lethargy. There are three sorts of leprosy—the squamous, or scaly, the crustaceous, in which the skin is covered with crusts, and the tuberculous. The remedy recommended for this disgusting disease is light food, such as vegetables, soups, milk: sulphur baths, sudorific drinks, mercury, are sometimes prescribed. But all remedies are too frequently unavailing. In the middle ages, leprosy, under all the forms of disease to which this term has been applied, seems to have been very common and general. It should, however, be observed, that almost all cutaneous disorders were considered as of a leprous nature, and treated as such. From the sixth to the fifteenth century, these loathsome disorders attracted the attention of lawgivers and of the benevolent, and we find numerous ordinances relating to lepers, affecting their civil rights, and great numbers of leper-houses in all the countries of Europe. In the historians of those times, therefore, we are to consider the word *leprosy* as used indiscriminately of all cutaneous diseases; and we may well be astonished and shocked to find that all such patients were treated somewhat after the manner prescribed in Leviticus for the Jewish leprosy. They were, in fact, treated as civilly dead: their funeral obsequies were performed, and masses said for the benefit of their souls. Their marriage ties were dissolved, but a leper might enter into a new connexion with a person who was also afflicted with the disease. They were allowed to enter the cities at certain seasons, but were required to give notice of their approach by sounding a rattle. The consequences of such a treatment may be easily imagined. The improved condition of the lower classes, in food, clothing, and manner of living in general, and the advancement of medical science, have contributed to eradicate this loathsome and disgusting malady.

LERMA, FRANCIS DE ROXAS DE SANDOVAL, duke de, first minister of Philip III. of Spain, was marquis of Denia, when he was appointed equerry to the Infant don Philip, over whom he acquired such influence, that, when the prince ascended the throne, in 1598, he made him his favourite and prime minister. He concluded peace with Britain and Holland, and endeavoured to relieve the embarrassed state of the finances, by encouraging agriculture; but his measures were ill-contrived. After the death of his wife, he took the ecclesiastical habit, and obtained a cardinal's hat, which he conceived would protect him in the possession of his power. But he was deceived; for

his own son, the duke D'Uzeda, contrived to supplant him in the king's favour, and succeeded to his post on his being dismissed, in 1618. He was accused, without any probability, of having employed his secretary, Roderic Calderon, to poison the queen. For this imaginary crime, Calderon was executed at the next reign. The duke of Lerma died in retirement, in 1625.

LESAGE, ALAIN RENE; a celebrated French novelist and dramatic writer. He was born May 6 1668, at Sarzeau, a small town in Brittany, and was the son of a lawyer, who held an office in the court of Rhys. His father dying in 1682, he was placed under the guardianship of an uncle who dissipated the fortune of his ward. He studied at the college of the Jesuits, at Vannes, after which he appears to have been employed in his native province for five or six years. In 1692, he went to Paris to study philosophy, and also to solicit some employment. His talents and manners procured him admission into the best society, where his wit and taste for elegant literature rendered his company very acceptable. His first literary undertaking was a translation from the Greek of the *Letters of Aristarchus* (1695). Established as a resident in the capital, he was admitted an advocate of parliament; and the abbé De Lyonne gave him a pension of 600 livres. He studied the Spanish language, and produced a multitude of translations or imitations of Castilian dramas and romances. Two of his comedies were published in 1700, and a third was acted in 1702; but a war not till 1707, when his *Crispin, Rival de son Maître*, appeared, that he established his reputation as a theatrical writer. His success as a novelist has not contributed to make him known to foreigners. *Le Diable Boiteux*, the title of which has been easily translated "The Devil upon two Sticks," became extremely popular; and *Gil Blas de Santillane* (1716) has furnished a model for numberless imitations in various countries and languages. Lesage prepared a translation of the Orlando of Ariosto, and published in 1717—21, *Roland l'Amoureux*, from Balafrin, as an introduction to the former, which was never executed. In 1732, he published *Les Aventures de Guzman d'Alfarache* (two vols., 12mo; and the following year, *Les Aventures de Robert, dit le Chevalier de Beuchefne* (two vols., 12mo), containing the real history of a freebooter, from papers bequeathed by his widow. In 1734, appeared *L'Étude d'Estevanille Gonzales* (two vols., 12mo); and, in 1738, an amusing dialogue, entitled *L'air Journeux de Parques* (12mo). The last of his novels was *le Bachelier de Salamanque*, which La Harpe considers as inferior to all the preceding. He did not cease writing, but, in 1740, produced a collection of satirical letters, under the title of *La Lettre trouvée*, and, in 1743, a volume of anecdotes. In the year last mentioned, he retired to Boulogne, where he died Nov. 17, 1747. Lesage produced a great number of comic pieces for the theatre, seven of which he published in his *Théâtre Français* (1739, two vols., 12mo), including *Crispin Rival de son Maître*, and *Trecairet*, intended as a satire on the farmers-general. Notwithstanding his talents, and the success of his numerous compositions, the author of *Gil Blas* was by no means rich, owing to a carelessness and liberality of disposition, which prevented him from soliciting the great for employments, or from steadily accumulating the products of his literary industry.

LESBOS (now *Metelin*, from the former capital, Mytilene, once the residence of Aristarchus, and a Turkish fortress); a Greek island, 137 miles in circumference, containing 260 square miles, 20,000 inhabitants, for the most part Turks, in the southern corner of the Ægean sea (the Archipelago), on the

Asiatic coast. According to tradition, Lesbos, son of Lapithas, and grandson of Æolus, by the advice of an oracle, led a colony to this island, espoused Methymna, daughter of Macareus, and received with her the dominion of half of the island, to which he gave the name of *Lesbos*, it having been previously called *Iea*, and *Pelægia*, from the Pelasgians. The island contained forests of beech, cypress, and fir trees. It yielded marble of a common quality, and the plains abounded in grain. Warm springs were also found; agates and precious stones. The most profitable production was wine, which was preferred, in many countries, to all the other Greek wines. To the present day, the oil and figs of Lesbos are accounted the best in the Archipelago. The island formerly contained nine cities, for the most part in a flourishing condition; among them, Mitylene, Pyrrha, Methymna, Arisba, Eressus, and Antissa: at present, 120 villages are enumerated. Lesbos was originally inhabited by Æolians, who formed a powerful democracy from an insignificant monarchy. They afterwards made great conquests on the continent and former territory of Troy, and even resisted the Athenians themselves. Lesbos was next disturbed by the Samians, and, afterwards, by the Persians, to whom it was finally obliged to submit. After the battle of Mycale, it shook off the Persian yoke, and became the ally of Athens. During the Peloponnesian war, it separated, more than once, from Athens, but was always reduced to obedience. A distinguished citizen of Mitylene, exasperated that several rich inhabitants had refused his sons their daughters in marriage, publicly accused the city of an intention to conclude a league with the Lacedæmonians, by which false accusation he induced the Athenians to send a fleet against Lesbos. The nearest cities, Methymna excepted, armed in defence of their capital, but were overpowered, the walls of Mitylene demolished, and a thousand of the richest inhabitants put to death. The territory of Methymna alone was spared. The island itself was divided into 3000 parts, of which 300 were devoted to the service of the gods, and the rest divided among the Athenians, by whom they were rented to the ancient proprietors. The cities of Lesbos, nevertheless, soon rebelled again. The Lesbians were, moreover, notorious for their dissolute manners, and the whole island was regarded as the abode of leasure and licentiousness. At the same time, they had the reputation of the highest refinement, and of the most distinguished intellectual cultivation. Poetry and music made great progress there. The Lesbian school of music was celebrated, and said to have had the following origin: When Orpheus was torn to pieces by the Bacchantes, his head and lyre were thrown into the river Hebrus, and both were cast, by the waves, on the shore of Methymna. Meanwhile, harmonious sounds were uttered by the mouth of Orpheus, accompanied by the lyre, which was moved by the breath of the wind. The Methymnians therefore buried the head, and suspended the lyre in the temple of Apollo. In honour, the talent of music was conferred on them by this deity. In reality, Lesbos produced musicians superior to all the other musicians of Greece. Among these, the most distinguished were Arion, Methymna, and Terpander of Antissa. Alcæus and Sappho were esteemed the first in lyric poetry. The seven wise men, the philosophers Theophrastus and Theophranes (the bosom friend of the great Pompey), and the historians Herodotus, Myrtillus, &c., were also natives of this island. It was often chosen as a place of residence for distinguished foreigners. Epicurus and Aristotle spent their youth there.

LESLIE, SIR JOHN, professor of natural philosophy in the university of Edinburgh, and distinguished by his valuable writings and discoveries, was born at the kirk-town of Largo, in Fife, on the 16th of April, 1766. His father, Robert Leslie, by profession a joiner and cabinet-maker, was a much respected and worthy man, and seems, in point of education and general attainments, to have been superior to the majority of persons in his station at that period. When very young, he was sent to a woman's school in the village, but remained only a short time there. Afterwards he was placed under a Mr Thomson at Lundin Mill, with whom he learned to write; and lastly he went to Leven school, and began to learn Latin; but being a weakly boy, and unable to walk so far, he was obliged after about six weeks to give up attendance. He received, while at home, some lessons in mathematics from his elder brother Alexander, and soon began to show a surprising aptitude for that branch of science; but to Latin he took a strong dislike, and could not be induced to resume the study of it till after his first year at college. His extraordinary proficiency in geometrical exercises, joined to a consideration of the unfavourable circumstances under which he had acquired it, brought him at an early period under the notice of professors Robinson and Stewart, of the university of Edinburgh. He was sent to the university of St Andrews in 1779, and at the first distribution of prizes, attracted some attention by his proficiency, which was the means of introducing him to the patronage of the earl of Kinnoull. Being destined for the church, he went through the regular routine of instructions for six sessions at St Andrews, and then removed to Edinburgh, in company with James, (now Sir James) Ivory. At the university of Edinburgh Mr Leslie studied three years, during which time he was introduced to Dr Adam Smith, and employed by that eminent man in assisting the studies of his nephew, afterwards lord Reston.

In 1788, he went to Virginia, as tutor to two young college friends; and after spending more than a year in America, returned to Edinburgh. In January, 1790, he proceeded to London, carrying with him some recommendatory letters from Dr Smith. His first intention was to deliver lectures on natural philosophy; but being disappointed in his views, he found it expedient to commence writing for periodical works, as the readiest means of obtaining subsistence. About three months after his arrival in London, he made an agreement with Mr Murray, the bookseller, to translate Buffon's Natural History of Birds, which was published in 1793, in nine octavo volumes. The sum he received for it laid the foundation of that pecuniary independence which, unlike many other men of genius, his prudent habits fortunately enabled him early to attain. During the progress of the translation, he fulfilled an engagement with the Messrs Wedgewood of Etruria in Staffordshire, to superintend their studies; he left them in 1792. In 1794, Mr Leslie spent a short time in Holland; and, in 1796, he made the tour of Germany and Switzerland with Mr Thomas Wedgewood. About this period, he stood candidate for a chair at St Andrews, and subsequently, for that of natural philosophy at Glasgow, but without success. He invented that beautiful instrument the Differential Thermometer about the year 1800. The results of his inquiries into the nature and laws of heat, in which he was so much aided by this exquisite instrument, were published to the world in 1804, in his celebrated "Essay on the Nature and Propagation of Heat." The work was honoured, in the following year, by the council of

the Royal Society, with the Rumford Medals. In consequence of the translation of professor Playfair from the chair of mathematics to that of natural philosophy in the university of Edinburgh, the former became vacant, and Mr Leslie appeared as a candidate. A party in the Scottish church, inspired by a jealousy of his liberal principles in politics, accompanied by a desire of advancing one of their own number, opposed his election, on the ground of what they deemed an infidel note in his essay on heat; but after a keen contest, Mr Leslie was successful.

Through the assistance of one of his ingenious contrivances—his hygrometer—he arrived in 1810 at the discovery of that singularly beautiful process of artificial congelation, which enabled him to convert water and mercury into ice.

In 1809, Mr Leslie published his *Elements of Geometry*, which immediately became a class-book, and has since gone through four editions. He also published, in 1813, an "Account of Experiments and Instruments depending on the relation of Air to Heat and Moisture." In 1817, he produced his "Philosophy of Arithmetic, exhibiting a Progressive view of the Theory and Progress of Calculation," a small octavo; and, in 1821, his "Geometrical Analysis, and Geometry of Curve Lines, being volume second of a Course of Mathematics, and designed as an Introduction to the study of Natural Philosophy." In 1822, he published "Elements of Natural Philosophy," for the use of his class—reprinted in 1829—and of which only one volume appeared. "Rudiments of Geometry," a small octavo, published 1828, and designed for popular use, was his last separate work. Besides these separate works, he wrote many admirable articles in the *Edinburgh Review*, three profound treatises in *Nicholson's Philosophical Journal*, a few in the *Transactions of the Royal Society of Edinburgh*, and several very valuable articles on different branches of physics in the Supplement to the *Encyclopædia Britannica*. In 1819, on the death of professor Playfair, whose promotion had formerly made room for him in the chair of mathematics, he was elevated to the professorship of natural philosophy, by which his powers were of course brought into a far wider field of display and of usefulness, than they had been for the preceding fourteen years. Among the preliminary treatises of the seventh edition of the *Encyclopædia Britannica*, which began to be published in 1830, he wrote a "Discourse on the History of Mathematical and Physical Science, during the eighteenth century," which may be described as one of the most agreeable and masterly of all his compositions.

The income enjoyed by Mr Leslie was for many years so much above his necessities, that he was able, by careful management, to realise a fortune not far short of ten thousand pounds. Part of this he expended, in his latter years, upon the purchase and decoration of a mansion called Coates, near his native village, where he spent all the intervals allowed by his college duties. Early in the year 1832, at the recommendation of the lord chancellor (Brougham), he was invested with a knighthood of the Guelphic order, at the same time that Messrs Herschel, C. Bell, Ivory, Brewster, South, and Harris Nicolas, received a similar honour. Sir John Leslie was not destined long to enjoy the well-merited honour. In the end of October, while superintending some of the improvements about his much-loved place, he incautiously exposed himself to wet, the consequence of which was a severe cold. He neglected his ailment, and was speedily seized with erysipelas in one of his legs.

On Wednesday, October 31st, he again exposed himself in his grounds, and from that day his malady advanced very rapidly. On the evening of Saturday, November 3, 1832, he breathed his last. *LESSPINASSE. See Espinasse.*

LESSING, GOTTHOLD EPHRAIM, one of the most distinguished German authors, who contributed more than any other individual to the regeneration of German literature, and whose language is a model of German prose, was remarkable for the versatility of his genius. Lessing was born January 22, 1729, at Kaments, a town in Upper Lusatia. His father, a strict Lutheran clergyman, gave him his first rigorous instruction. In 1741, Lessing was sent to the school at Meissen, where he studied Greek, Latin, and mathematics with great success. In 1744, he entered the university of Leipsic, but could never be induced to devote himself to a strict routine of prescribed study. Here he became acquainted with several young men, afterwards distinguished in literature; and, in connexion with a friend named Voss, he translated the *Hannibal* of Marivaux, and prepared for the stage a dramatic performance by which he was at school. This was brought forward by a stage directress named Neuber, with whom he was acquainted. Actors were at that time considered as vagabonds, and his father, much distressed at his son's mode of life, ordered him to return home. Here he wrote his *Anacronauts*, though wise as love were little akin to the sobriety of his station. In 1750, Lessing went to Berlin, where he contributed to several periodicals, and attracted some attention by his correspondence with Voltaire, occasioned by Richier, Voltaire's amanuensis, having shown him a copy of Voltaire's *Vie de Charles XII.*, before it was published. In compliance with the anxious wishes of his parents, he then went to Wittenberg, and applied himself, with his younger brother, very diligently to his studies. At this time, he translated Hume's (q. v.) *Trial of Wits*, and wrote a notice on Klopstock's *Messiah*. In 1753, he returned to Berlin, and wrote the learned articles in *Voss's* *Zeitung*. In 1755, he wrote his tragedy of *Semiramide*, at Potsdam. In the same year, he set out on a tour, with Mr Winkler, a merchant; but, in consequence of the breaking out of the seven years' war, they only proceeded to Holland. In 1757, in connexion with Nicolai and Mendelssohn, he edited the *Library of Belles-Lettres*. He also began his *Urgenia*, which was subsequently completed under the name of Emilia Galeotti, and is much the most elaborately finished of his works. In 1760, Lessing became a member of the royal academy of sciences at Berlin, and soon after became secretary to general Tauentzien, in Breslau, wrote *Minna von Barnheim*, a military comedy, and his *Laocœon*, or *On the Limits of Poetry and Painting*, and began deeper researches into philosophical and theological subjects, though at the same time, he followed his inclination for games of hazard more than previously. In 1764, he once more returned to Berlin, to devote himself solely to the sciences; but, unaccustomed to an ordinary life, he is said to have formed the plan of putting himself at the head of a company of strolling players. We shall not therefore be surprised to find him, in 1767, in Hamburg, whither the managers of the theatre had invited him on very moderate terms. While there, he wrote his *Dramaturgie*; but a misunderstanding with his employers, and the docility of the actors, rendered his residence at Hamburg disagreeable. At the same time began his dispute, or it may more properly be called quarrel, with Klotz. Dissatisfied with his situation, he was now determined to go to Italy, where an advantageous offer of the place of librarian at Weimar re-

changed his intention. The little court of Brunswick was then almost the only one in Germany which fostered German literature: the others confined their attention to the French. In 1769, he left Hamburg. In the library of Wolfenbüttel, he discovered the MSS. of the *exubantior* Berengarius of Tours, in which he refutes the work of the *transubstantiator* Lanfrancus. He also published some theological treatises, under the title of Wolfenbüttel Fragments of an unknown Author, which involved him in a theological war. In 1775, he went to Vienna, having received an invitation to that city, and accompanied prince Leopold of Brunswick to Italy, which he had long desired to see. He left Germany in April, but returned the same year; and the theological disputes in which he was involved, now became so acrimonious, that it was proposed, at Wolfenbüttel, to subject his writings to a strict censorship. His Nathan the Wise, from its supposed irreligious tendency, added to the fierceness of the controversy. As a poem, it is, in our opinion, much the finest that he has written. The persecutions which he encountered destroyed his peace, and he died February 15, 1781. His complete works were published at Berlin (1771, et seq.); another edition (Berlin, 1796, et seq. 30 vols.); to which must be added his Correspondence, in 2 vols. (Berlin, 1798); a new edition appeared at Berlin (1824), in 34 vols.; a pocket edition has been published at the same place since 1825. Lessing's Thoughts and Opinions, collected and explained from his Writings, by F. Schlegel, appeared at Leipsic (1804, 3 vols.). His brother, K. G. Lessing, published an account of his life (Berlin, 1793, 2 vols.).

LESTOCQ, JOHN HERMANN; a favourite of the Russian empress Elizabeth, twice elevated by fortune to be twice precipitated from his high honours. Lestocq was born in Hanover, in 1692, of French parents, who had fled from the religious persecutions of Louis XIV. He studied surgery under his father, went to Russia, then a good field for men of talents, and entered the service of Peter the Great, as a surgeon, and enjoyed his entire confidence. A sudden change in the emperor's dispositions towards him took place, and Lestocq, without knowing the cause, was banished to Kasan. Catharine I. recalled him after the death of Peter, and gave him the place of surgeon at the court of her daughter Elizabeth. Entirely devoted to the interests of his mistress, he offered her his assistance in gaining possession of the crown, after the death of Peter II., but his daring plans were then rejected. Eleven years later (1740), when the youth of Ivan, and the regency of his mother Anne, again presented an opportunity, his advice was adopted. The active and politic Lestocq guided the daring enterprise, never, even in moments of the greatest danger, losing his presence of mind, and, November 21, 1741, Elizabeth ascended the throne. The new empress made him her privy counsellor, and chief physician, and director-general of medical institutions. The king of Poland created him count, and sent him his miniature to be worn in his button-hole, like an order. In compliance with the wishes of the empress, Lestocq was obliged to interfere in affairs foreign to his province. This circumstance, and the frankness of his character, increased the number of his enemies, who succeeded in exciting the suspicions of the empress. Lestocq was arrested in 1748, and confined in the fortress of St Petersburg for trial. At first, he bore this change of circumstances with cheerfulness and calmness; but when he was to be subjected to the rack, he confessed himself guilty. He was deprived of all his honours and estates, and banished to Uglitsch, where he remained three years, and then to Ustjug-Veliki, where he was in prison

nine years. His third wife, Maria Aurora, shared the fate of her husband with an exemplary firmness. When Peter III. ascended the throne, Lestocq was restored to his honours. Catharine II. continued his pension without his offices. He died in 1767.

LESTRANGE, SIR ROGER, a political partisan and controversialist, was the youngest son of Sir Hammond Lestrange, knight, of Hunstanton-hall, Norfolk, where he was born in 1616. His father, being a zealous royalist, brought up his son in the same principles. At the age of twenty-two, he attended Charles I. in his expedition into Scotland, and laid a plan for surprising Lynn, but being detected with the king's commission in his pocket, he was tried by a court martial, as a spy, and condemned. He was, however, respited from time to time, until he had lain in prison four years, when, by the connivance of his gaoler, he made his escape to the continent. On the dissolution of the long parliament, he returned home. On the restoration, he was made licenser of the press—a profitable post. In 1663, he set up the Public Intelligencer, which he discontinued on the design, then concerted, of publishing a London Gazette, the first number of which appeared February 4, 1665. In 1679, he set up a paper, called the Observer, in defence of the measures of the court. In 1687, he was obliged to give up the Observer, because he could not agree with James, who had knighted him, in the doctrine of toleration, although he had written in favour of the dispensing power. His death took place in 1704, at the age of eighty-eight, his faculties having become impaired some years before. He was the author of a great number of political tracts, full of coarse and virulent abuse, and in a style so rude and vulgar, that he was regarded by Granger as one of the great corrupters of the English language. Lestrange translated Josephus (his best work), Cicero's Offices, Seneca's Morals, Quevedo's Visions, &c.

LESUEUR, EUSTACHE, one of the most distinguished French painters, born at Paris, in 1617, was instructed in drawing by his father, a statuary, and was afterwards placed at the school of Simon Vouet, the true founder of the French school of painting. He soon distinguished himself by several pieces in the true Italian style; but his reputation was not completely established till he had executed his paintings for the Carthusian monastery in Paris. In twenty-two pictures, he delineated (1649—1651), the principal scenes in the life of St Bruno, the founder of the order. Lithographic sketches of this work were published at Paris, in 1822 and 23. In 1650, he painted, for the corporation of goldsmiths, the preaching of the apostle Paul at Ephesus. This painting was presented to the church of Notre-Dame, and was exhibited annually on the first of May. His next works were a Magdalen and a St Lawrence, and, in 1651, two scenes from the life of St Martin, &c. Among the most distinguished of his later works are some mythological scenes in the hotel Lambert relating to Cupid and the Muses with Apollo. After completing this work, he died, in the thirty-eighth year of his age. Incessant toil, and the jealousy of his companions in art, brought him to his grave. His countrymen call him the *French Raphael*, and it is not to be denied that he had great merit. His conceptions are noble and elevated; his composition is simple, careful, and well arranged; the drawing is correct, in good taste, and proves his diligent study of the antique and of the great Italian masters, particularly of Raphael; his drapery is artfully disposed, and executed with great truth. His figures are full of animation and character; the positions are various, and free from manner. He displays great boldness and freedom of pencil; his colouring is delicate and simple, but deficient in truth and

vigour, which sometimes renders his pictures too uniform, and occasionally they have too much ornament. That Lesueur should have reached so great excellence, is the more remarkable, as he had never been out of France, hardly even out of Paris, and had consequently formed himself after the few models of the ancient art and the Italian school to be found there. He had studied Raphael chiefly through the engravings of Mark Antony. Lesueur, from his education, may be considered as the true representative of the French school; for Poussin, who was a superior artist, belongs more to the Italians than to the French. His mild and ingenuous character made him generally esteemed, although the jealousy of his competitor Lebrun, who tyrannized over the taste and opinions of the day, prevented him from enjoying the reputation which was justly due him in his lifetime.

LESUEUR, JEAN BAPTISTE, a musical composer, a descendant of the great painter Lesueur, born in 1763, was placed in the musical school of the cathedral of Amiens, and, after completing his musical studies, was made director of music in the cathedrals at Sees and Dijon, and, in 1784, in the church of the Innocents, at Paris. In 1786, in opposition to several candidates, he received the place of master in the cathedral of Paris, and his elevated and impressive compositions, no less than the excellent manner in which he led the orchestra, made him a universal favourite. His own inclinations, and the advice of Sacchini, induced him to compose for the theatre. Telemachus was his first opera, which was brought forward with great success in the theatre Feydeau. In 1788, Lesueur resigned his place at Notre-Dame, that he might devote his time to theatrical music, and lived, till 1792, with his friend and patron Bochart de Champagny, in whose house he applied himself so laboriously, that his host, anxious for his health, would not allow him lights for more than half the night. Lesueur was at that time engaged in writing his opera *La Caverne*: one night, his light went out, and, unable to endure any interruption, he lay on the floor before the fire, and continued to write by the feeble light afforded by a few pieces of wood, until he was found in that situation the next morning, by Mr Champagny. After various disappointments, he finally succeeded, in 1793, in introducing this opera on the stage, which met with the most brilliant applause. On Chenier's proposition, he was made professor of music in the national institute, and wrote several pieces of music for festivals, during the time of the republic; was afterwards displaced by intrigue, but again restored by Bonaparte. In 1793, he composed *Paul et Virginie*, the Death of Adam, and the Bards. This last and finest work, in which the composer appears to have called up the very spirit of Ossian, delighted Napoleon to such a degree, that he made him chapel-master at the Tuileries, conferred on him the order of the legion of honour, and presented him a gold snuff-box, with the inscription—"The emperor of the French to the author of the Bards." Lesueur wrote, in connexion with Cherubini, Méhul, Langlé, and Rigal, the work published by Catel (1816), *Sur les Principes élémentaires de Musique*. He also wrote *Essai sur la Musique sacrée* (1787), and *Lettres et Réponse à Gaillard, sur l'Opéra de la Mort d'Adam, et sur plusieurs Points d'Utilité relatifs aux Arts et aux Lettres* (1801).

LETHARGY (*lethargus*, from *λῆθη*, forgetfulness); a heavy and constant sleep, with scarcely any intervals of waking. When awakened, the person answers, hut, ignorant or forgetful of what he said, immediately sinks into the same state of sleep. It is considered as an imperfect apoplexy, and is mostly symptomatic.

LETHE; a river of the lower regions, celebrated

in ancient mythology, whose water had the power of making the souls of the departed, who drank of it, forget all their sufferings on earth. Those spirits, in particular, drank of it, who were destined to return to the upper world in new bodies, in order to forget the pleasures enjoyed in Elysium.

LETO. See *Latona*.

LETTER OF ATTORNEY. See *Attorney*.

LETTER OF MART, or of MARQUE; a commission granted to the commander of a merchant ship, or privateer, to cruise against and make prize of the enemy's ships and vessels, either at sea or in their harbours, under pretence of making reprisals for injuries received. The ship so commissioned is also called a *letter of mart* or *marque*.

LETTERS. See *Types*, and *Writing*.

LETTER-WRITING. Among the letters celebrated in French literature are those of *Madame de Sevigné*, *Ninon de Lenclos*, *Babet*, *Racine*, *Voltaire*, and the collection of *Richelet*; in English literature, the letters of *James Howell*, *Sir William Temple*, *Addison*, *Pope*, *Swift*, *Bolingbroke*, *Lady Montague*, *Chesterfield*, *Gray*, and *Cowper*, are celebrated; in Italian, those of *Manusio*, *Ludovico Dolce*, *condotto Bembo*, *Bestivoglio*, *Bernardo Tasso*, those collected by *Lud. Dolce*, and *Annibal Caro*, those of *Pietro Aretino*, *Algarotti*, and *Gasparo Gombi*; in German literature, the letters of *Lessing*, *Winckelmann*, *Klopstock*, *Wieland*, *Gellert*, *Weisse*, *Jacobi*, *Caro*, *Abbt*, *Sturm*, *Gleim*, *Burger*, *Lichtenberg*, *J. von Muller*, *Mathieson*, &c. *Bolingbroke* made use of the epistolary form for treating philosophical subjects (for instance, the study of history), and *Richardson* applied it to novels. The Germans also have delicate letters by *Mendelssohn*, *Jacobi*, *Herder*, *J. von Muller*, and *J. G. Muller*. In the French as well as the Italian literature, letters form a very considerable branch, and large collections of them exist, among which are the following: *Lettres historiques* (14 vols., Hague, 1692—1698, 12mo); *Lettres historiques et galantes par Madame de Noyers* (6 vols., Utrecht, 1713, 12mo); *Lettres édifiantes et curieuses, écrites des Missions étrangères* (34 parts in 22 vols., Paris, 1717—1776, 12mo; new edition, 26 vols., Paris, 1790—1793, 12mo; also in 26 vols., Toulon, 1810—1812, 12mo, and an atlas); *Nouvelles Lettres édif.* (6 vols., Paris, 1819); *Lettres écrites à et à d'indes* (12 vols., Hague, 1729—1740); *Lettres Juives* (6 vols., Amsterdam, 1736; new edition, 1782); *Lettres cabalistiques* (6 vols., Hague, 1781); *Lettres Chinoises* (5 vols., Hague, 1730); *Lettres Portugaises* (2 vols., Paris, 1796). Among the Italian collections, are *Lettre vulgari di diocesi nobilissime Romini et eccellentissimi Ingegneri* (3 vols., Venice, 1566, also 1567); *Lettre d'Uomini illustri, che furono nel Principio del Sec. XVII.* (Venice, 1744); *Lettre Sanesi sopra le Belle Arti* (3 vols., with engraving, Venice and Rome, 1762—1786, 4to).

LETTUCE (*lactuca sativa*); a smooth, herbaceous, annual plant, containing a milky juice, which has been cultivated from remote antiquity, and is a general use as a salad. The original locality is unknown. The stem grows to the height of about two feet, and bears small pale-yellow flowers. The inferior leaves are sessile, and undulate on the margin. The young plant only is eaten, as it is succulent and poisonous when in flower. Twenty species of *lactuca* are known, from various parts of the globe.

LEUCADIA (at present, Santa Maura, 112 square miles, 17,500 inhabitants); an island belonging to the republic of the Ionian Islands, on the western coast of Greece. The southern extremity (on which stood a temple of Apollo), at present cape Durazzo, is the vicinity of the capital, Leucas (at present, *Sa Maura*). was called by the Greeks the *Leucadian Point*. A

was famous for the festival annually celebrated there, and the (so called) *Leucadian leap*. At every festival, a criminal was thrown from the rock into the sea, as a sin-offering, loaded, as it were, with all the sins of the people. He wore a dress of feathers, and even living birds were fastened to him, so that he generally fell gently, without much injury, into the deep, whence he was taken out, but was obliged to leave the country for ever. No less remarkable was the leap, which many performed of their own accord, from this rock, to free themselves from the tortures of unhappy love. It is said that some tried it more than once; but the unhappy lovers generally met with death in the waves. Among the latter are mentioned two females—Artemisia, queen of Caria, and Sappho. See *Sappho*.

LEUCÆTHIOPS. See *Albino*.

LEUCHTENBERG; a lordship (before 1806 a landgraviate, with a princely title, and a seat and vote in the diet), situated in the ancient Nordgau, on the river Nab, in the Upper Palatinate, in the Bavarian circle of Regen. It comprises eighty-four square miles, with 5300 inhabitants. Pfeimbit is the chief place. The late king of Bavaria conferred the lordship, in 1817, on his son-in-law Eugene, ex-vice-roy of Italy, with the principality of Eichstadt, held immediately of the crown. Eugene took the title of duke of Leuchtenberg, and made over to the crown of Bavaria the 5,000,000 of francs, which the king of the Two Sicilies was bound to pay him for his Neapolitan dotations. His dotations in the Lombardo-Venetian kingdom were given up to Austria, for 7,000,000, and he retained possession of those in the Mark of Ancona, the income of which is estimated at 850,000 francs annually. The income of the duke (exclusive of the interests of his large capital) amounts to 1,600,000 francs. The present duke Augustus was born December 9, 1810. His sister Josephine, born March 14, 1807, is crown-princess of Sweden; Amelia, born July 31, 1812, ex-empress of the Brazils. There are several other children.

LEUCIPPUS; the founder of the atomistic school in Greek philosophy, and teacher of Democritus. By some he is said to have been a native of Abdera; by others, of Elea; and by others, of the island Melos. He lived 500 years B. C. His instructor was Zeno the Eleatic. To settle a contest between reason and sensible experience, which had been mainly excited by the Eleatic school, he invented his system, which he opposed to that of the Eleatics. The more ancient Eleatics denied the reality of motion, vacuity of space, and plurality of matter, reducing all that exists to a single, eternal, and immutable substance. Leucippus, on the contrary, assumed the infinity of space. In this space, there are, according to his view, an infinite quantity of particles of matter, too minute to be perceptible to the senses. In themselves, they are indivisible (thence the name *atoms*); for, if an infinite divisibility were ascribed to them, they would at last disappear into nothing. Now, these atoms move from eternity in infinite space, and by their union and separation, form the origin and end of things, since unity can never become plurality, nor plurality become unity, the atoms cannot, by their connexion, produce a true unity, but mere aggregations. In substance, all the atoms are similar, but of an infinite variety of shapes, by which is explained the variety of bodies formed by them. Atoms are moreover distinguished by their local situation, and the order in which they are compounded. Situation and order are the fundamental properties of the atoms; from their union and separation arise properties of the second order (*qualitates secundariæ*), such as hardness, softness, colour, sound, smell, &c. As far as can be deduced from the imperfect notices which we

have, Leucippus explained the origin of the world by the motion of atoms, in the following manner:—From the infinity of atoms, some broke loose, and, becoming confused, produced a rotatory motion by means of which, similar particles were associated with similar particles, while the dissimilar were repelled. From the necessary inequality of the velocity of the bodies, the smaller were driven to the outside, and formed, as it were, an envelop around a kernel. The grosser bodies of this envelop sank downwards, and, by their mutual collisions, attenuated the envelop. The bodies that sank downwards compose the earth; the envelop itself was finally inflamed, and gave rise to the stars. To fire he ascribed round atoms. The atoms composing the other elements—water, air and earth—were distinguished merely by magnitude. Fire, as the most subtile, the lightest and most fluid element, he made the soul of the world, the principle of life, sensation and thought. These last modifications, however, according to Leucippus, were not always founded in the nature of atoms, but merely in the mode of their aggregation. The intellectual substance (consisting of particles of fire) is diffused through the whole body. Men and animals inhale it with the atmosphere, and hence life ceases with the end of respiration. There is nothing said in his system respecting the soul of the universe, a providence, or Deity.

LEUCITE, or AMPHIGENE, is a mineral which occurs in little masses, having the appearance of crystals rounded by attrition; also in crystals whose form is that of the trapezohedron, apparently with cleavages parallel to the rhombic dodecahedron and cube, the latter of which, being the most simple of the two, has been adopted as the form of the primary crystal. Colour grayish white; translucent; lustre vitreous; fracture conchoidal; specific gravity 2.37. Before the blow-pipe alone, it is infusible; with borax, it fuses into a transparent glass. It consists of 53.75 silice, 24.62 of alumine, and 21.35 of potash. It is found only in volcanic and trap rocks. The lavas of Vesuvius and basalts of Italy abound with it. It is especially abundant between Rome and Frascati.

LEUCO; two syllables found in many scientific terms or geographical names, derived from the Greek λευκος, white.

LEUCOTHEA. See *Ino*.

LEUCTRA; a village in Bœotia (at present, Livadia), famous for the great battle in the year 371 B. C., which the Theban Epaminondas won over the Spartan king Cleombrotus, thus putting an end to the great influence which Sparta had exerted for several centuries over all Greece.

LEUSDEN, JOHN; a celebrated biblical critic and theologian, born in 1624, at Utrecht, where he afterwards obtained the professorship of Hebrew, with the reputation of being one of the most erudite scholars and able divines of the age. He published a new edition of the books of the Old Testament, in the original Hebrew (in 2 vols., 8vo), and of those of the New, in Greek and Latin (one thick 12mo); a Hebrew and Latin Lexicon; an edition of Poole's Synopsis (5 vols., folio); *Versio Septuaginta Interpretum*; *Clavis Græcæ Novi Testamenti*; *Onomasticon Sacrum*; *Philologus Hebræus et Philologus Hebræomixtus*; *Clavis Hebræica et Philologica Vet. Test.*; a Hebrew Psalter, and Commentaries on the Books of the Prophets Joel, Hosea, and Jonah. Leusden died in his native city, about the close of the seventeenth century.

LEUTHEN; a village in Lower Saxony, west of Breslau, famous on account of a battle gained here by Frederic the Great, December 5, 1757, over prince Charles of Lorraine. See *Seven Years' War*.

LEUWENHOEK, ANTHONY; a celebrated natural philosopher, born at Delft, in Holland, in 1632. His skill in grinding optical glasses led the way to the making of microscopical observations, which procured him no small degree of fame. He began to publish an account of his discoveries in the English Philosophical Transactions, in 1673; and they are continued from No. 94 to No. 380 of that collection. In 1680, he was chosen a fellow of the royal society; and, in 1698, he entertained the emperor Peter the Great, then at Delft, with an exhibition of his experiments. He appears to have passed the whole of his life at his native place, devoting his time to microscopical researches, chiefly relating to anatomy. He died in 1723. A Latin translation of his works in the Dutch language was published between 1695 and 1719 (4 vols., 4to), under the title of *Arcana Naturæ detecta*, and reprinted at Leyden, in 1722. His industry was great, but preconceived opinions sometimes led him to erroneous conclusions.

LEVAILLANT, FRANCIS, a celebrated traveller, born at Paramaribo, in the Dutch colony of Guiana (Surinam), from childhood displayed a passion for the study of natural history, particularly of ornithology. His desire of extending his knowledge by travelling in the most distant lands was increased in Europe. In Amsterdam, he found a patron in the person of Temmink, the great ornithologist, who warmly encouraged his plans, in the hope of obtaining through him, great accessions to his excellent collections in natural history, particularly ornithology—a hope which was not disappointed. Levaillant first proceeded to the cape of Good Hope, whence he advanced into the interior of Africa. The specimens which he collected on this occasion were entirely lost. The ship in which they were embarked for Holland was attacked by the British, and burned in the course of the action. Supported by Temmink, Levaillant renewed his labours, and, with a tolerably large caravan, directed his course to the countries on the north of the colony. Insurmountable obstacles prevented him from pursuing his adventurous researches so far into the interior as he wished. The fruits of his labours were, however, important. He was not less fortunate in a second excursion. Levaillant died at Paris, November, 1824, aged seventy. It has been objected to his accounts, that they are not always accurate, and that they are often improbable, though this cannot be satisfactorily shown. His readers are interested by his lively descriptions, and by an attractive philosophical originality. His accounts of his first and second excursions were published in French, in 1789 and 1796. He also left some works on natural history, and some separate treatises. The most important of these works are *Histoire naturelle des Oiseaux d'Afrique* (1799—1807, in fifty numbers, folio), and the *Histoire naturelle des Perroquets* (1801—1805, 2 vols., folio).

LEVANT (Italian, *il Levante*; French, *le Levant*; the east). This term is applied, in a general sense, to the countries on the eastern coast of the Mediterranean sea, and, in a more contracted sense, to the Asiatic coasts of the Archipelago, from Constantinople to Alexandria, in Egypt. The most famous of the commercial cities of the Levant, taken in this narrow sense (among the French, *échelles du Levant*), besides Constantinople and Alexandria, are Smyrna, Scanderoun (Alexandretta), and Aleppo. Smyrna, with 100,000 inhabitants is the principal commercial place of the Levant, and the grand mart of the Asiatic trade. This Levant Proper is under the Turkish dominion, has a very warm climate, many mountains, and very fertile plains, and is inhabited by Turks, Armenians and Greeks. The staples are grain, rice,

tobacco, olives, cotton, silk, Angora goat's hair, safflower, and some minerals. The *Levant coffee*, as it is called, does not grow in the Levant, but to Arabia, and has this name because it is exported from the ports of the Levant. See Turner's *Travels in the Levant*, London, 1820, and count Forbin's *Travels in the East*.

LEVEE (from the French word *lever*, to rise, and the time of rising) is a word used in high life, or court language, for the ceremonial visits which great personages receive in the morning, as it were at their rising. The levee is distinguished from the drawing room, inasmuch as, at the levee of a gentleman, gentlemen only appear, and at the levee of a lady, only ladies, while, at the drawing-room, ladies and gentlemen both are admitted. At the levees and drawing-rooms of the sovereigns, persons of distinction, or young members of noble families, are introduced. On the first presentation of daughters of dukes, marquises and earls, it is customary for the queen of Britain to kiss them on the cheek. The word *levee* is also used in the United States of America, for the reception of company by the president.

LEVEE (French); an embankment on the banks of a river, to confine it within its natural channel. The lower part of Louisiana, which has been formed by encroachments upon the sea, is subject to be inundated by the Mississippi and its various branches, for a distance of more than 300 miles. In order to protect the rich lands on these rivers, mounds are thrown up of clay, cypress logs, and green turf, sometimes to the height of fifteen feet, with a breadth of thirty feet at the base. These, in the language of that part of the country, are called *levees*. They extend for hundreds of miles; and, when the rivers are full, extensive fields, covered with rich crops, and studded with villages are seen lying far below the river course. The giving way of these *levees*, sometimes occasioned by a sudden and violent pressure of the water, and sometimes by accidental perforations, is called a *couvre* (French, a disruption).

LEVEE-EN-MASSÉ (universal rising): a military expression for the rising of a whole people, including all capable of bearing arms, who are not otherwise engaged in the regular service. When animated by patriotic feelings, it is the most formidable obstacle which an enemy can encounter: and it is unsurpassable, if favoured by the nature of the ground, because almost every advantage is on the side of the people. They fight on their own soil; they know the ground; they find support and assistance in every house, from every woman and child; they fight for their own hearths; they enclose the enemy on all sides, and can destroy whatever may be useful to him, cut off his communications, pursue, annoy, disturb, harass him incessantly, so that he can effect nothing except getting possession of the strong places. It is called *Landsturm* (landstorm), in German, in distinction from the *Landwehr* (militia). This distinction was first made in 1796, when the peasants of Rhine and Franconia, fell upon the rear of the French under Jourdan, with much success. The *Landsturm* was yet more effective in 1799, and in 1813, the governments of Northern Germany called it forth in every part of the country. It consisted of every man person capable of bearing arms of any sort, whose age or other reasons exempted from the regular service. Orders were issued to turn every thing into weapons, to defend the country by every means, and to injure the enemy in all possible ways, by destroying provisions and wells, attacking stragglers, intercepting couriers, and escorting prisoners. The *Landsturm* was useful at the siege of several fortresses. Its organization was founded on municipal divisions.

Napoleon ordered the *levée en-masse*, when the allies entered France, and it threatened to become dangerous to them; but the capture of Paris put an end to the war. We all know how effectual a *levée en-masse* was in Spain, where even women took part in it, and in Tyrol, under Hofer. We lately witnessed a *levée en-masse*, in Poland. The French national guard, with its different classes, might be considered a *levée en-masse* organized on a gigantic plan. The chief difference between a *levée en-masse* and militia is, that, in the former, all persons are comprised not included in the latter; and they do not march far from home; and that their service is more irregular, and even owes its strength, in some measure, to this irregularity.

**LEVEL**; a mathematical instrument used for drawing a line parallel to the horizon, and continuing it at pleasure, and, by this means, for finding the true level, or the difference of ascent or descent between several places, for conveying water, draining fens, placing the surfaces of floors, &c., level, and for various other purposes in architecture, agriculture, hydraulics, surveying, &c. There is a great variety of instruments for this purpose, differently constructed, constituted of different metals, according to the particular purposes to which they are applied; as the carpenter's level, mason's level, balance level, mercurial levels, surveying and spiral levels; but, however their construction may vary, they may all be referred to the following three classes: 1. those in which the vertical line is determined by a suspended plumb-line or a balance-weight, and the horizontal position is shown by a line perpendicular to it; 2. those which determine a level line by the surface of a fluid; 3. spirit levels, which point out the horizontal direction by a bubble of air floating in a fluid contained in a glass tube. 1. Those of the first kind, depending upon the plumb-line, are very common, but not very accurate. The simplest form is that of two rulers united in the form of the letter L; they must be exactly perpendicular to each other; then, if a plumb-line is suspended from the top of the vertical ruler, and the edge thereof be made to coincide with the plumb-line, the other ruler must be horizontal. This, when applied to the top of a wall, a beam, or a floor, will show if they are horizontal. This is the kind of level used by artificers; sometimes it is formed like the letter A, of three rulers. The plumb-line being suspended from the vertex, and the two legs set on the surface to be levelled. The line hangs opposite to a mark made on the middle of the cross ruler, when the feet are on the same level. Sometimes the horizontal piece crosses the perpendicular at its foot, and the plumb, suspended from the top of the perpendicular, is received in an opening at their junction. 2. The *water level* shows the horizontal line by means of a surface of water or other fluid, founded on this principle, that water always places itself horizontally. The most simple kind, made of a long wooden trough, which is filled with water, shows on its surface the line of level. This is the ancient *chorobates*. The water level is also made with two cups fitted to the two ends of a straight pipe, an inch in diameter, and four feet long. The water communicates from one cup to the other; and this pipe being movable on its stand by a ball and socket, when the two cups are seen to be equally full of water, their two surfaces mark the line of level. This instrument, instead of cups, may also be made with two short cylinders of glass, three or four inches long, fastened to each extremity of the pipe with wax or mastich. The pipe, filled with coloured water, shows itself through the cylinders, by means of which the line of level is determined; the height of the water, with respect to the centre of the earth,

being always the same in both cylinders. This level, though very simple, is yet very commodious for levelling small distances. 3. The *spirit or air level* shows the exact level, by means of a bubble of air, enclosed, with some fluid, in a glass tube of an indeterminate length and thickness, and having its two ends hermetically sealed. When the bubble fixes itself at a mark in the middle of the tube, the case in which it is fixed is then level. When it is not level, the bubble will rise to one end. This glass tube may be set in another of brass, having an aperture in the middle, where the bubble may be observed. The liquor with which the tube is filled, is oil of tartar, or *aqua secunda*, those not being liable to freeze, as common water, nor to rarefaction and condensation, as spirit of wine is. These instances will explain the principle of the different kinds of levels. Their varieties are too numerous to be described here.

**LEVEN**; a river which flows from Loch Lomond, and, after a course of about nine miles, falls into the Clyde at Dumbarton. Smollett has celebrated it in a well-known little poem. Printfields and other public works are now established on its banks. *Leven* is also the name of a river in Fifeshire, which flows from Loch Leven.

**LEVEN, LOCH**; a lake of Scotland, about ten miles in circumference, in the county of Kinross. It contains four islands, on one of which was formerly a priory, and on another stand the remains of the castle of Loch Leven, once a royal residence, which was granted by Robert III. to Douglas. In this castle Mary Stuart was confined, after her separation from Bothwell, and her capture by the confederate lords, at the battle of Carberry Hill. After several unsuccessful attempts, she made her escape, by the aid of George Douglas, her keeper's brother.

**LEVER**, in mechanics; an inflexible right line, rod, or beam, supported, in a single point, on a fulcrum or prop, and used for the raising of weights, being either void of weight of itself, or at least, having such a weight as may be commodiously counterbalanced. The lever is the first of those called *mechanical powers*, or *simple machines*, as being, of all others, the most simple; and is chiefly applied for raising weights to small heights. See *Mechanics*.

**LEVESQUE, PETER CHARLES**; a French writer on history and general literature, was born at Paris, in 1736, and, when young, apprenticed to an engraver. Displaying a strong inclination for learning, he was removed to the *collège Mazarin*, where he studied with great success. His family having retired into the country, he, for some time, supported himself at Paris, by working as an engraver. In 1773, he went to St Petersburg, with a recommendation from Diderot to the empress of Russia, who appointed him professor of belles-lettres at the school of noble cadets. Here he formed the design of writing the history of Russia, and, having completed the work, in 1780 he returned to Paris to publish it. He was admitted into the academy of inscriptions, and, some years after was appointed professor at the royal college. He was subsequently made a member of the national institute; and, in 1812, closed a long life devoted to literary pursuits. Besides his Russian history (4th edition with notes by Malte-Brun and Depping, eight volumes, 1812, a standard work on Russia), he produced a translation of Thucydides; a History of France, under the five first Kings of the House of Valois; a Critical History of the Roman Republic (three volumes); Studies in ancient History, and in the History of Greece, and many other translations and valuable works.

**LEVI**; the third son of Jacob and Leah. The prince of the Schemites, having ravished his sister Dinah, he, with his brother Simeon, attacked their

city while they were suffering the consequences of circumcision, to which they had submitted, and murdered all the males. Jacob reproaches them with this act of cruelty, on his death-bed, and threatens them with the dispersion of their descendants. Moses and Aaron were of this tribe. The Levites were set apart, by Moses for the service of religion, thus forming a hereditary caste of priests, or religious ministers, who received territories scattered about in the lands of the other tribes. The third book of Moses is called *Leviticus*, as it relates principally to the organization of the ministry. The Mosaic law is sometimes also called the *Levitical law*. See *Moses*.

**LEVIATHAN** (*Hebrew*) is compounded of two words, meaning a *great fish*, and *fastened*; hence it probably means a huge fish covered with close scales. The Septuagint renders it *δράκων* (a dragon), and *καρχήδων* (a whale). From the description given of it in the book of Job (xli.), it is usually considered to mean the crocodile, though some have supposed it to be the whale. See *Harris's Natural History of the Bible*.

**LEVITES.** See *Levi*.

**LEVITICUS.** See *Levi*.

**LEWIS.** *Harris and Lewis* is the name bestowed on one of the largest and most northerly of the Hebrides, the southern part of which is called *Harris*, and the northern *Lewis*. Lewis extends south-west and north-east eighty-two miles, and it is from ten to twenty-three miles in breadth, containing an area of 902 square miles, or 451,000 Scots acres. It lies between 5° 40' and 7° 10' W. lon., and 57° 54' and 58° 28' N. lat. Lewis belongs to the county of Ross; Harris to Inverness-shire. Lewis is divided into four parishes: Barvas, Lochs, Stornaway, and Uig. Besides some hamlets, there is only one town, viz: Stornaway, which lies on the east side of the island, at the head of a bay. The surface of the country is less rugged than that of Harris; the east side of the district is principally pasture land, and the west side is arable. On the coasts are numerous bays and inlets, where great quantities of shellfish are found; and the fisheries of herrings and cod are prosecuted with success. The rivers abound with trout, and in the season with salmon. The land animals are horses, black-cattle, deer, sheep, goats, and hogs, all which are of small size. Population of Lewis, in 1831; Barvas, 3011; Lochs, 3067; Stornaway, 5422; Uig, 3041; total, 14,541. See *Harris*.

**LEWIS, MATTHEW GREGORY**, an English writer, whose attempts, both in the departments of the drama and of romance, obtained at one period, a very considerable share of popularity, though but too frequently disfigured by bad taste, and degraded by licentiousness, was the son of a gentleman of good property, who was under-secretary at war. The subject of this article was born in the metropolis, in 1773, and educated at Westminster; on quitting which he travelled for improvement, especially into Germany, the literature of which country produced a strong impression upon him, and gave that peculiar turn to his compositions, which placed him in the foremost rank among the delineators of the marvellous and terrific, and has since loaded the shelves of circulating libraries with hosts of imitators, most of whom exhibit all the extravagances without the genius of their model. Of his writings, the first and most celebrated was the *Monk*, a romance, in three vols., 12mo, which, although much decried for its licentiousness, ran through a great number of editions; *Fœdral Tyrants*, ditto, 4 vols.; *Romantic Tales*, 4 vols.; *Tales of Wonder*, in verse, 1 vol., 8vo; *Tales of Terror*, 1 vol., 8vo; the *Castle Spectre*, a romantic drama; *Adelmorn the Outlaw*, ditto; *Venoni*, a tragedy; a volume of miscellaneous poetry, and the *Bravo of Venice* (a translation from

the German), 1 vol., 8vo. Mr Lewis had a seat in parliament, but seldom took part in the business of the house. His death took place in 1818, at sea, while on his voyage home from a visit to his West Indian possessions.

**LEWIS, MERIWETHER**, a celebrated explorer, was born near the town of Charlottesville, in Virginia, August 18, 1774. His father, a man of independent fortune, died when he was yet a child. He very early gave proofs of that bold and enterprising disposition for which he was subsequently so distinguished. At the age of eighteen, he relinquished academic studies, and engaged in the pursuit of a farmer, with which he continued to occupy himself until he was twenty. General Washington having called out a body of militia, in consequence of the disturbances in the western parts of the country, produced by discontent at the excise taxes, young Lewis enrolled himself in it as a volunteer, and soon that situation was removed to the regular service. In 1803, president Jefferson proposed to congress to send some competent person on an exploring expedition to the western part of the continent of North America, who might ascend the Missouri, cross the Stony mountains, and descend the nearest river to the Pacific. Congress having approved the proposition, and voted a sum of money for carrying it into execution, captain Lewis, who had then been nearly two years with Mr Jefferson as his private secretary, was chosen for that purpose. The following testimony of Mr Jefferson gives an idea of his views for the task: "Of courage undaunted; possessing a firmness and perseverance of purpose which nothing but impossibilities could divert from its direction; careful as a father of those committed to his charge, yet steady in the maintenance of order and discipline; intimate with the Indian character, customs, and principles; habituated to the hunting life, guarded, by exact observation of the vegetables and animals of his own country, against losing time in the description of objects already possessed; honest, disinterested, liberal, of sound understanding, and a fidelity to truth so scrupulous, that whatever he should report would be as certain as if sworn by ourselves: with all these qualifications, as if created and implanted by nature, in one body, for the express purpose, I could have no hesitation in confiding the enterprise to him." That there might be some person with him to assume the conduct of the expedition in case of accident to himself, William Clarke was appointed, at Lewis's request, to accompany him, and received a commission of captain. (For the particulars of this expedition, see the account which has been published of it—*Expédition &c.*—Philadelphia, 1814, 2 vols.). It was highly successful, and occupied three years, the party engaged in it having set out in the summer of 1805, and returned in the autumn of 1806. Lewis was soon afterwards made governor of the territory of Louisiana, and Clarke a general of its militia, and agent of the United States for Indian affairs. On the new governor's arrival at St Louis, the next of administration, he found the country torn by dissensions; but his moderation, impartiality, and firmness soon brought matters into a regular train. He was object to constitutional hypochondria, and, while under the influence of a severe attack of this disorder, put an end to his life, in 1809, at the age of thirty-six.

**LEWISS RIVER**; a river of North America, which rises in the Rocky mountains, and runs north-west into the Columbia, 413 miles from its mouth. length, about 900 miles.

**LEXINGTON**; one of the principal towns of Kentucky, capital of Fayette county, on a branch of the Elkhorn, 22 miles S. E. of Frankfort, 22 : of

Cincinnati; lon. 84° 18' W.; lat. 38° 6' N. The place derived its name from the circumstance that some hunters were engaged on the spot in laying out a town (1775), when a messenger arrived with the news of the battle of Lexington, and they immediately decided to commemorate that event by giving the name to the place. Population, in 1830, 5699. The staple manufactures of the place are cordage and bagging. Transylvania university, at Lexington, was incorporated in 1798, and organized anew in 1818. In 1830, it had 143 under-graduates, 62 in the preparatory department, 200 medical students, and 19 law students.

LEXINGTON, a small town in Massachusetts, about twelve miles north-west of Boston, and six south-east of Concord, is remarkable, in the history of the American revolution, as the place where the first British blood was shed in armed resistance to the mother country. On the evening of April 18, 1775, a detachment of British troops was sent from Boston, by general Gage, for the purpose of seizing some provincial stores at Concord. Notice of this movement having been communicated to the inhabitants on the route, the militia of Lexington, about seventy men in number, were hastily drawn up on the common, by which the road to Concord passes. The British commander, colonel Smith, having commanded them to disperse without effect, ordered his men to fire. Seven Americans were killed, and three wounded, and the company dispersed, several of the militia discharging their muskets as they retreated. The British troops then pushed on to Concord, the Americans retiring beyond the river which flows by the village. One hundred men were detached to destroy the bridge, across which the colonists had retired; they were, however, repulsed by the latter, and, at noon, the whole detachment took up the march for Boston. The militia of the neighbouring towns had meanwhile been collected, and began to hang upon the rear of the British with an irregular but destructive fire from every favourable position. At Lexington, the British were relieved by a reinforcement of 1000 men, but were still pursued in the same galling manner till their arrival at Charlestown, in the evening. (See *Phinney's History of the Battle at Lexington*, Boston, United States, 1825.) A simple monument of granite, bearing the names of those who fell, was erected at Lexington, by the commonwealth of Massachusetts, in 1799.

#### LEX LOCI CONTRACTUS (*conflict of laws*).

It is a general doctrine, that every government has jurisdiction of persons within its territories, and also of acts done within them. It follows, that all contracts made, and obligations assumed, have an implied reference to the laws of the place of the transaction, unless it appear otherwise on the face of the contract. Some contracts, however, have reference to different places for their execution, as a bill of lading for a foreign voyage, a foreign bill of exchange and many others. Such contracts necessarily refer to the laws of other countries than that in which the contract is made, in respect to the acts contemplated to be done abroad. The manner of execution of the contract must, in this respect, be governed by the foreign laws. But, for the purpose of ascertaining the meaning of the parties, regard is necessarily had to the language, laws, and customs of the place where it is made. In neighbouring territories subject to different jurisdictions, where there is much business and intercourse between the inhabitants of the different territories, as is, or, at least, formerly was the case in the different provinces of Holland and the Netherlands, and the territories bordering upon them, questions frequently arise as to the code of laws which is applicable to particular acts of the

parties, or provisions of contracts. Many questions have arisen in those countries, for instance, respecting the obligations and rights arising on the marriage contract, where the parties were married in one province or country, and afterwards removed to another. As to rights of property, consequent immediately upon a marriage, the laws of the place of marriage prevail; but it will often happen that these laws clash with those of the quarter to which the parties remove, and, in such cases, the general rule is, to give the laws of the place of the contract the preference, as far as is practicable. But it will sometimes happen that it is quite impossible to give them entire effect. The French law, for instance, makes the law of marriage, to many purposes, a pecuniary copartnership, and its provisions and remedies are adapted to this construction, and there is no difficulty in enforcing the rights of the wife under it. But in Britain and the United States, it is quite otherwise, as the wife's personal property, and the use of her real estate, go to the husband, and her legal rights are in a great degree suspended during the marriage. If, therefore, parties, married in France, remove to Britain or the United States, whatever respect might be paid to the French law, and the rights and obligations, as to property, arising on the marriage contract under that law, the laws of Britain or the United States, supply no forms of proceeding, and remedies adapted to such a construction of the contract. As to the acts done and the management of their property after their removal, therefore, they must be governed by the laws of the country of their residence. This question, as to the code of laws which is applicable, arises in relation to the adjustment of general average losses on vessels and their cargoes, it being a rule that such losses are to be adjusted at the port of delivery of the goods; and, where this is a foreign port, the adjustment is necessarily made according to the laws there prevailing. The implied contract between the parties to a bill of lading, to contribute to such average, where the contribution accrues abroad, has reference to the laws of the foreign port as to the proportion of the contribution.

LEY, or LEES; a term usually applied to any alkaline solution made by levigating ashes that contain an alkali. Soapless is an alkali used by soap-boilers, or potash or soda in solution, and made caustic by lime. Lees of wine are the refuse, or sediment deposited from wine standing quiet.

LEYDEN (*Lugdunum Batavorum*); a large and beautiful city in the government of South Holland, situated on a branch of the Rhine, with 3000 houses and 28,600 inhabitants; lon. 4° 29' E.; lat. 52° 9' N. It has wide streets (the one called *Broad Street* is among the finest in Europe), and numerous canals. The university of Leyden, formerly very celebrated, was founded in 1575, and is distinguished for its botanical garden, anatomical theatre, observatory, and valuable library with 60,000 volumes and 14,000 manuscripts. The number of students, in 1827, was 323. The *Annales Acad. Lugd. Bat.* are still continued. Cabinets of philosophical, surgical, chemical instruments, and one for natural history, belong to the university. Among the buildings, the principal are St Peter's church, with the tombs of Boerhaave, Peter Camper, and Meerman, and the stadthouse, which contains Luke of Leyden's excellent picture of the last judgment. A fine view of the whole city is enjoyed from the ancient castle, considered, traditionally, a Roman work. The printing establishments formerly constituted an important branch of the industry of Leyden, but are much less extensive at present. The city has woollen manufactures, and considerable inland

trade. The manufactures have much declined, but the salt-works are important. Leyden suffered much in January, 1807, from the explosion of a ship containing 40,000 pounds of gunpowder. The houses on the side of the canal were overturned, and many persons killed. Natives of Leyden are John of Leyden (q. v.), known as the leader of the Anabaptists, the celebrated Peter Muschenbroek, Rembrandt, Luke of Leyden, &c. It is connected with Haarlem, Hague, and Delft by canals. Leyden was called by the Romans *Lugdunum Batavorum* (see *Batavians*), from which the present name was formed in the middle ages. Even in Ptolemy's time, Leyden was a considerable city. It suffered much during the war with Spain (1574).

LEYDEN, JAN or JOHN OF. See *John of Leyden*.

LEYDEN, LUKE OF. See *Luke of Leyden*.

LEYDEN, JOHN; a poet, antiquary, and Orientalist, was born at Denholm, in Roxburghshire, Scotland, in 1775, of parents in humble circumstances, and bred up to such country labour as suited his condition. In his earliest youth, he displayed the greatest eagerness for the acquisition of knowledge, but enjoyed few opportunities of gratifying it. His predominant desire for learning, however, determined his parents to prepare him for the church, and he was entered at the college of Edinburgh, in 1790, for the purpose of commencing his professional studies. Here, besides attending to theology, he cultivated medical studies, and, in addition to the learned languages, acquired French, Spanish, Italian, German, the ancient Icelandic, Arabic, and Persian. After remaining five or six years in Edinburgh, he became private tutor to two young gentlemen, whom he accompanied to St Andrews, and, in 1799, published his *History of African Discoveries*, which has since been continued and enlarged by Hugh Murray (3 vols., 8vo, 1820). At this time, he was also the author of many poetical effusions in different departments, which appeared in the *Edinburgh Magazine*, and which, by rendering him known to the lovers of literature, introduced him into the best society in the Scottish capital. In company, he displayed the rudeness and independence, which his early life and education were fitted to produce in a man of strong feeling and vigorous genius, united with personal boldness, and much bodily power and activity. In 1800, he began to preach, and, although popular as a pulpit orator, he was not satisfied with his own discourses. In 1801 and 1802 he assisted Sir Walter Scott in procuring materials and illustrations for his *Minstrelsy of the Scottish Border*, and re-published the *Complaynt of Scotland*, with a learned preliminary Dissertation, Notes, and a Glossary. Having manifested a strong desire to set out on an expedition to explore the unknown regions of Africa, his friends, to prevent the execution of this project, procured him an appointment in India, which, however, could only be held by a person who had taken a surgical degree, and this he actually obtained, after six months' unremitting application. While in India, he devoted himself to the study of Oriental literature, but did not long survive the influence of the climate and his over-exertions in his studies. He died in 1806. His *Poetical Remains*, with a Memoir of his Life, were published in 1821, and, in 1826, the *Commentaries of Bâher*, translated by him from the Turkish language. An animated sketch of doctor Leyden's life is to be found among the *Miscellaneous prose Works* of Sir W. Scott.

LEYDEN PHIAL, in electricity, is a glass phial or jar, coated both within and without with tin-foil, or some other conducting substance, which may be charged, and employed in a variety of useful and

entertaining experiments. Glass of any other shape so coated and used, has also received the same denomination. A vacuum produced in such a phial, has been named the *Leyden vacuum*. See *Electricity*.

LI, (called also *caire*); the common copper coin, in China, with a square hole in the middle, and an inscription on one side. The copper is alloyed with lead, and the coin, which is cast, is very brittle. Ten li make one candarren, 100 a mass, 1,000 a liang or tale, about five shillings.

LIAS, in geology; the name of a peculiar formation, consisting of thick, argillaceous deposits, which constitutes the base on which the *conglomerate* and *reposes*. The word *lias* is of English origin, and is said to be derived from a provincial pronunciation of the word *layers*. The upper portion of these deposits, including about two thirds of their total depth, consists of beds of a deep-blue marl, containing a few irregular limestone beds. In the lower portion, the limestone beds increase in frequency, and assume the peculiar aspect which characterizes the *lias*, presenting a series of thin, stony beds, separated by narrow, argillaceous partings; so that the series of this rock, at a distance, assume a striped and ribband-like appearance. These limestone beds, when purest, contain ninety per cent. of carbonate of lime, the residue consisting, apparently, of alumina, iron, and silex. In places where these beds are less pure, alumine of course abounds. The blue *lias*, which contains much iron, affords a strong lime, distinguished by its property of setting under water. The white *lias* takes a polish, and may be used for the purposes of lithography. The *lias* clay often occurs in the form of soft slate or shale, which derives its very thin *laminae*, and is frequently much impregnated with bitumen and iron pyrites; in consequence of which, when laid in heaps with faggots, and ignited, it will continue to burn slowly until the pyrites is wholly decomposed. When it falls in large masses from the cliffs upon the sea-shore, as it does in England, and becomes moistened by sea-water, it ignites spontaneously. The *lias* of Whitby, in England, is of this sort. *Lias* is impregnated with a large dose of common salt, sulphate of magnesia and soda; in consequence of which, springs of water, rising through it, contain these salts in solution. The Cheltenham and Worcester springs are in this clay. The *lias* is remarkable for the number and variety of its organic remains, among which are numerous *chamæna*, univalves, bivalves, certain species of fish and several animals, allied to the order of *Ichthyosaurus*, which are of enormous size. The *Ichthyosaurus*, one of these, has the orbit of its eye ten inches wide; and seven broad; and the *Plesiosaurus*, of which two species have been found, measures twenty feet in length. This rock also embraces, in some strata, bones of the turtle, fossil wood, and *yc.* The *lias* crosses England from near Whitby, in Yorkshire, to Lyme, in Dorsetshire. The same formation occurs also in France, and in the Alps and the Jura. The most valuable mineral substances obtained from *lias* are water-setting lime and alum shale.

LIBANUS, MOUNT. See *Lebanon*.

LIBATION (Latin, *libatio*, *libationem*, from *libare*, to pour out); properly a drink-offering, but used also for other offerings to the gods, as a cake, or something similar placed on the altar, and a part of which was burned. *Libations* were also made at domestic meals, some of the food being thrown into the fire on the hearth, in honour of the *lares*. Of all fruits, a small portion was always placed on an altar, table, &c., in honour of the gods, or thrown into the sea in honour of the *Neptunes*.

The libations to the dead were not performed till the ninth day after the burning or interment, and consisted of milk, wine, or blood, and generally concluded the funeral solemnities. In sacrifices, the priest was first obliged to taste the wine with which he sprinkled the victims, and cause those to do the same who offered the sacrifice. This ceremony was called *libare*, (*delibare*), whence it also means to touch or taste something. Among the Greeks; the *εὐχὴ*, or *λαχὴ*, was similar to the *libatio* of the Romans.

LIBEL, in law, is defined to be the malicious defamation of any person, made public either by writing, printing, or pictures, in order to provoke him to anger, or to expose him to public hatred, contempt, or ridicule. When defamatory words are merely spoken in conversation, they exist no longer than during the act of giving them utterance, and are heard only by those in whose presence they are used; but, when they are committed to paper, they become permanent in their nature, and are capable of being disseminated far and wide. Words, again, may be spoken in haste, and without thought; but the act of writing necessarily requires time and deliberation. For these reasons, libelling is regarded, by our law, as a more heinous offence than slandering, which is the technical name for spoken defamation; and numberless expressions are libellous, if written and made public, which are not punishable, if they are merely spoken. Thus, unless the slanderous words be such as tend to cause it to be believed, that the person slandered is guilty of some crime punishable by law, as theft or perjury, or that he is infected with some disease which renders him unfit to mix in society; or unless they tend to injure him in the particular trade from which he derives his livelihood; or unless they have actually been productive of some damage to him, they are not actionable, though false. For instance, it is not legal slander to say of a private gentleman, that he is a swindler; if he has received no specific damage therefrom, beyond the mere annoyance of having been subjected to such an imputation. But such accusations as these, and all others which hold up individuals to public hatred, contempt, or ridicule, become libellous when the remembrance of them is deliberately perpetuated by their being committed to writing. Libellers may be brought to punishment by a prosecution on the part of the government, or be compelled to make reparation by a civil action. The civil action is grounded upon the injury which the libel is supposed to occasion to the individual; the public prosecution upon its tendency to provoke a breach of the peace. If the charges contained in the libel are true, a civil action cannot be maintained, because it is considered that every man must bear the consequences of his own act; and, therefore, if he has laid himself open to accusation, he must endure it as the natural result of his own crimes or folly. But, inasmuch as the malicious propagation even of that which is true, is calculated to disturb the public peace, the truth of the libellous matter is no defence, by the common law, upon a prosecution by the government, although, without doubt, it will, in many cases entitle the defendant to the merciful consideration of the court, when it decides upon the *quantum* of punishment to be awarded. In civil actions, again, it is necessary to prove that the publication of the libel was made to others besides the person at whom it is aimed; for, however false and atrocious it may be, it is evident that the person libelled can derive no injury from it, so long as its very existence is known to none but himself. Therefore an abusive letter, written by one man to another, is not sufficiently published to support an action, unless the writer shows it to a third

person, because the person to whom it was addressed cannot be injured by it, unless he himself chooses to make it public; nevertheless, the author of such a letter may be prosecuted by indictment, for it equally tends to create a breach of the peace. With these distinctions, civil actions and prosecutions for libel stand very much on the same footing. In ordinary cases, it is not necessary to prove malice on the part of the libeller; for, even supposing that the libel was published without any malicious design, yet the injury to the individual, and the danger to the public peace, are not the less on that account. But, although the charges contained in a libel are false, yet under the particular circumstances of certain cases, the author is excused, unless express proof can be produced of his having been influenced by hatred or malice. These are called *privileged communications*. The master who gives a bad character of the servant who has left him, is privileged, if he acts *bona fide*, and not officiously; but if, without application being made to him to give a character, he volunteers officially to send one to the person who is about to hire the servant, he is not privileged, and must stand or fall with the truth or falsehood of his charges. So, if a father writes to his son, *bona fide*, warning him against a person whose character he has reason to suspect, that is a privileged communication. It is difficult to lay down any general definition, which shall comprise all the occasions when communications are privileged; but, perhaps, we shall not be far wrong in saying that, whenever a communication is made *bona fide*, unofficiously, and without malice, and either the person who makes it, or the person to whom it is made, has a real substantial interest in the subject to which it relates, it is a privileged communication, and the mere fact of its not being true will not render the person who makes it liable, either to a civil action, or to a criminal prosecution. A fair criticism on a public work, or print, &c.; a fair comment on a place of public entertainment; a fair and impartial account of the proceedings in a court of justice, and the like, are not considered libellous, unless the subjects to which they relate are in themselves of such an obscene, blasphemous, or scandalous nature, that a due regard to decency enjoins that they should not be publicly discussed, under which circumstances, even a correct statement becomes indictable. In a civil action, the plaintiff recovers damages, the amount of which is settled by the jury. But, upon an indictment, the jury has merely to acquit the defendant, or to find him guilty, after which the court passes judgment, and awards the punishment, which is generally fine or imprisonment, or both; but, by statute 1 George IV., c. 8, persons convicted a second time of a blasphemous or seditious libel, may be banished for such a term of years as the court thinks fit. The jury decide on the legal innocence or criminality of the alleged libel, without being bound by the direction of the judge. See *Jury*.

LIBEL, in the ecclesiastical and admiralty courts, is the name given to the formal written statement of the complainant's ground of complaint against the defendant.

LIBER; a surname of Bacchus among the Romans, referring to the idea of a deliverer, or liberator. Liber was originally an old Italian god of fertility, whose name was probably derived from the old word *libare* (to pour out, to water). He was worshipped in connexion with Libera (Proserpine) and Ceres.

LIBERAL. In the article *Arts*, the name of *liberal arts* is said to have been given, originally, to those which were considered suitable for freemen, in contradistinction to those which were left to slaves. In modern times, the word *liberal* has received a peculiar political meaning. The two great parties

throughout Europe, are composed of those who adhere to the ancient *régime*, and object to the principles of equal rights, and of those who, adhering to the latter, are thence called *liberals*. The struggle is between the feudal, or aristocratic, and the democratic principle. There exists, of course, a great variety of shades in both parties.

LIBERAL ARTS. See *Arts*.

LIBERIA; the name which, in 1824, on the motion of general Robert Goodloe Harper, was given to the territory purchased by the American colonization society, on the western coast of Africa. The origin and purposes of this association have been already described in the article *Colonization Society*, as well as the ill success of the first attempt to establish a settlement, in 1820. In the summer of 1821, cape Montserado, or Mesurado, with a large tract of adjoining country, was purchased of the native chiefs, or head-men. The emigrants first established themselves on cape Montserado, under the direction of doctor Ayres, Jan. 7, 1822. Almost immediately after taking possession of the cape, doctor Ayres was, in consequence of severe illness, obliged to return to the United States; but, happily for the colony, Mr Jebudi Ashmun arrived, and assumed the superintendence of affairs, Aug. 8. For more than six years, this able man devoted all his powers to the work of establishing, upon broad and sure foundations, this colony, so interesting to the United States, and so full of hope for Africa. His defence of the infant settlement, in December, 1822, against the united forces of the natives, showed great courage and talent. In 1824, the system of government now in operation was adopted, and the benefits which have resulted from it are great. The supreme power resides in the agent of the society, but all the civil and military officers of the colony are annually elected by the people. Through the negotiations of the late Mr Ashmun, great accessions were made to the original territory of Liberia. Full possession has been obtained of large tracts of country, and a jurisdiction (which excludes all foreign nations from making settlements) acquired over the coast, from cape Mount to Trade Town, a distance of 150 miles. The territory of Liberia is generally low upon the coast, but gradually rises towards the interior, and, at a distance of from twenty to thirty miles from the sea, hills are visible, of considerable elevation. About forty-eight miles due north-west from cape Montserado, is Grand Cape mount, which is elevated from a level country, on a base of about four miles in diameter, 900 feet above the sea, which washes it on three sides. This mount, the north-western extremity of Liberia bay, is covered with a deep and unfading foliage. Several springs of excellent water descend from it, and the Pissou river (a broad, but irregular and sluggish stream, which has been traced to about a hundred miles from its mouth) empties itself into the ocean on its northern side. The St Paul's river, which flows into Liberia bay, at the distance of from eight to nine miles north of cape Montserado, is of considerable magnitude, and supposed to admit, above its falls (about twenty miles from its mouth), of boat navigation for 200 or 300 miles. The Montserado river is forty miles long, and enters the sea on the northern side of the cape of the same name. In the Junk district, south-east of cape Montserado forty miles, are two considerable rivers, one descending from the north-north-west, and the other from east-north-east, and pouring their waters into the ocean at the distance of only two miles from each other. The river St John's, eighty-one miles south-east from cape Montserado, is larger than any we have mentioned and represented by Mr Ashmun as majestic, and navigable for vessels of 90 to 100 tons, abounding

with fish, and having its course through a fertile, delicious, and salubrious country, of a rich and low soil, fanned sixteen hours in every twenty-four, even in the dry season, by a sea breeze, tempered and sweetened, in its passage up the river, by the verdure which crowns its banks, rendering the scene one of the most delightful that can be imagined.

Cape Montserado, upon which is situated Monrovia (so called in honour of president Monroe, one of the earliest and most efficient friends of the colonization society), the earliest settlement made in Liberia, is about 6° 27' N. lat., and 10° 40' W. lon. from Greenwich. Cape Montserado is elevated about eighty feet above the ocean, is washed by the water on three sides, and connected with a level tract of land on the fourth. Its length, from north-west to south-east, is three and one third miles; its average width, from north-east to south-west directly across from the river to the ocean), three fourths of a mile. It comprehends about 1600 acres. From May to October, the wind, on this coast, is uniformly from south-south-west. In November and December, the sea breeze varies from south-south-west to north-north-west, the land breeze commonly from north-east and north. Masters of vessels should remember that the coast may, at all seasons, be descended with local difficulty; but, that the ascent, between January and May, is exceedingly slow, both the current and wind being in opposition. Vessels standing by cape Mount ought to give this cape a birth of two or three leagues. The anchorage ground, at the distance of one or two miles north-east of cape Montserado, is safe and good.

The American colonization society has transported to Liberia 1402 free persons of colour. Between 100 and 200 slaves, liberated from the grasp of pirates on the coast, have been placed under the protection of the colony. About 300 slaves, taken what about to be brought into the United States contrary to law, have been removed to Liberia by the government of the United States. There are four American settlements within the limits of the colony—Monrovia, Caldwell, the Half-way Farms (or New Georgia) and Millsburg, situated twenty miles in the interior on the eastern bank of the St Paul's. One of the native tribes has voluntarily placed itself under the laws of the colony, and others have expressed a desire to follow its example. The natives, in the vicinity of Liberia, may be divided into three great classes—the Fey or Vey tribes occupying the country from Canias river to Grand Cape mount, a distance of 50 miles, and which are estimated by Mr Ashmun at 1500. Between cape Mount and cape Montserado is the Dey tribe, about half the number of the Fey. South-west of Montserado are the Bassa, renowned over various countries. Their number may be estimated at 150,000. The Feys are described as proud, selfish, deceitful race; the Dey is unwarlike, and inoffensive, and the Bassa is industrious and many of them laborious. It is not to be understood, however, that each of these classes is altogether and directed by a single government. They are all of them broken up into small and feeble and utterly incapable of conducting warlike operations in a united and powerful manner. The people that in the interior are of a more elevated mind and civil character, have some knowledge of the American language, and some acquaintance with the useful arts. The articles to be obtained by trade in Liberia are chiefly ivory, carwood, coral, bone, shell, hides, the teeth of the sea-horse, and a quantity of coffee. The country abounds in cattle, goats, swine, and fowls, and in most of the productions of other tropical climates. The efforts of the American colonization society have been

attended with great, if not unexampled, success. The men of colour, who have migrated to Liberia, have felt the influences of enterprise and freedom, and are improved alike in their condition and character. Those who were slaves have become masters; those who were once dependent have become independent: once the objects of charity they are now benefactors, and the very individuals who, a few years ago, felt their spirits depressed in America, and incapable of high efforts and great achievements, now stand forth conscious of their dignity and power, sharing in all the privileges and honours of a respected, a free, and a Christian people.

**LIBERTAS**, among the Romans, personified liberty; according to Hyginus, a daughter of Jupiter and Juno. When she is represented on coins, with her head uncovered, she is the Roman Liberty; but, with a diadem and veil, she is the goddess Liberty, in general. Gracchus built a temple to the latter on mount Aventine.

**LIBERTINES**, or **LIBERTINI**; a sect of fanatics, in the sixteenth century, in Holland and Brabant, who placed religion in a perfect union of the soul with God, which having once taken place, all difference between evil and good, sin and virtue, ceased; so that the individual might give himself up to his appetites and passions, as these were no longer bad.

**LIBERTY OF THE PRESS.** See *Press*.

**LIBERTY TREE.** At the time of the disturbances excited in the American colonies by the stamp act, a large American elm was used, in Boston, to hang obnoxious characters in effigy, and to make known the intentions of the *sons of liberty* (as the patriots were called), who also held their meetings under it. The following inscription was placed upon it—"This tree was planted in the year 1646, and pruned by order of the sons of liberty, February 14, 1766." It was thenceforward called the *liberty tree*, but, in 1774, was cut down by the British troops, by whom the town was occupied. The example was imitated in other parts of the country, most of the towns having their liberty tree; and on the breaking out of the French Revolution (1789), the same emblem was adopted. A liberty tree was planted by the Jacobins in Paris, and many other cities of France followed their example. The same ceremony was practised by the French troops, on their entrance into foreign countries. The Lombardy poplar was first used, but the French name of this tree (*peuplier*), affording matter of derision, oaks or fir-trees were afterwards used.

**LIBERTY, CAP OF.** The right of covering the head was, in early times, a mark of liberty. Slaves always went bare-headed, and one of the ceremonies of emancipation was the placing a cap on their head, by their former master. Thus the cap (or the hat) became the symbol of liberty, and has played a part in many revolutions. The Swiss owe their liberty to the hat which Gessler ordered to be saluted as a mark of submission. The arms of the united Swiss cantons have a round hat for a crest. In England, the cap (blue, with a white border, and the inscription *Liberty*, in letters of gold), is used as a symbol of the constitutional liberty of the nation, and Britannia sometimes bears it on the point of her spear; more commonly, however, she has the trident of Neptune, without the cap, in her left hand, whilst she offers the olive branch of peace to the world in her right hand. The cap was used in France, as the symbol of liberty, at the beginning of the revolution (1789); and its red colour was borrowed from that of the liberated galley-slaves of Marseilles, who went in great numbers to *Paris*. The Jacobin club, at Paris, afterwards made the red cap a badge of membership, and it was, therefore, afterwards called the *Jacobin cap*.

**LIBRA**; the Roman pound unit for weighing. (See *As*.) The ancient Romans reckoned money also by pounds, and a *libra* of silver was worth about thirteen dollars. This word passed over to the various nations of Latin descent or mixture. See *Libre*.

**LIBRARIES.** The most ancient library is fabulously ascribed to the Egyptian king Osymandyas of Memphis. Pisistratus first founded a library among the Greeks, at Athens; Xerxes carried it to Persia, but Seleucus Nicator caused it to be restored to Athens. The most celebrated library of antiquity was the Alexandrian. (See *Alexandria*.) Emilius Paulus and Lucullus brought the first libraries, as the spoils of war, to Rome. Asinius Pollio founded the first public library, which was also taken in war. Julius Cæsar established a large library, and intrusted it to the care of the learned Varro. Augustus founded two libraries, one of which was called *Palatina*, because it was in the temple of Apollo, on mount Palatine; the other was in the portico of Octavia, and was called *Octaviana*. The conflagration of Nero destroyed several libraries, which Domitian restored. Trajan founded a very excellent library. Publius Victor mentions twenty-eight public libraries in Rome; there were, besides, extensive private libraries. These treasures were destroyed or dispersed, partly by the ravages of the barbarians, partly by the iconoclasts. In the ninth and eleventh centuries, Basil the Macedonian, emperor of the East, and the learned Comnenian imperial family, made several collections of books, principally in the convents of the Ægean islands and mount Athos. The Arabians had, in Alexandria, a considerable library of Arabian books. Al-Mamoun collected many Greek manuscripts in Bagdad. In the West, libraries were founded in the second half of the eighth century, by the encouragement of Charlemagne. In France, one of the most celebrated was that in the abbey St Germain des Prés, near Paris. In Germany, the libraries of Fulda, Corvey, and, in the eleventh century, that of Hirschau, were valuable. In Spain, in the twelfth century, the Moors had seventy public libraries, of which that of Cordova contained 250,000 volumes. In Britain and Italy, libraries were also founded with great zeal, particularly, in the former country, by Richard Aungerville; in the latter, by Petrarch, Boccaccio, and others. After the invention of the art of printing, this was done more easily and at less expense. Nicholas V. founded the Vatican library. Cardinal Bessarion bequeathed his excellent library to the church of St Mark at Venice. See Petit-Radel's interesting *Recherches sur les Bibliothèques anciennes et modernes jusqu'à la Fondation de la Bibliothèque Mazarine* (Paris, 1819.)

The principal libraries of modern times are, the royal library at Paris (more than 400,000 printed books, and 80,000 MSS.); the central court library at Munich (more than 400,000 books, and 9000 MSS.); the imperial library at Petersburg (300,000 books, and 11,000 MSS.); the imperial library at Vienna (300,000 books, and 12,000 MSS.); the university library at Gottingen (about 300,000 books); the royal library at Dresden (at least 220,000 printed books, 150,000 pamphlets, dissertations, and small works not included, and 2700 MSS.); the royal library at Copenhagen (stated variously at 130,000, 250,000, and 400,000 volumes; it has 3000 MSS.); the library in the Escorial (130,000 volumes, and excellent Arabian MSS.); the royal library at Berlin (200,000 volumes, and 7000 MSS.); the academical library at Prague (130,000 volumes, and 8000 MSS.); the royal library in Stuttgart (116,000 volumes); the Vatican library at Rome (360,000 books, and 40,000 MSS.). In Britain, the two largest libraries are the Bodleian in Oxford (stated by some at 500,000, by

others at 250,000 volumes, and 30,000 MSS.), and the library of the British museum at London (180,000 books, and about 60,000 MSS.). Besides the *Bibliothèque du roi*, there are, in Paris, those of the arsenal (150,000 printed books, 5000 MSS.), of St. Geneviève (110,000 printed books, 2000 MSS.); of the institute (30,000 volumes); of the chamber of deputies (40,000); the Mazarin library (90,000); making in all, 1,200,000 volumes in the public libraries in Paris. In the rest of France, there are 273 public libraries, the principal of which are those of Lyons (containing together 600,000 volumes); Bordeaux (105,000); Aix (73,000), &c. The total number of volumes, in these provincial libraries, is 3,000,000. Access to these great collections is easily obtained, both by natives and foreigners. In Italy, there are a great number of valuable libraries, of which that at Bologna, founded in 1650, contains 150,000 volumes, 9000 MSS.; the Magliabecchi library at Florence, 150,000 volumes, 9000 MSS.; the university library at Genoa, 70,000 volumes; the Ambrosian at Milan, 60,000 printed volumes, and, at least, 15,000 MSS.—according to others, 140,000 volumes, and 15,000 MSS.; that at Modena, 80,000 volumes, and that of Naples 130,000. The Vatican library is very large and famous, but in much disorder. The number of books in foreign libraries is very difficult to be ascertained with precision, and the statements differ so much, that the above estimates are, in many cases, little better than approximations. In the United States of America, the principal libraries are that of Harvard college (36,000 volumes); of the Boston Athenæum (26,000 volumes); of the Philadelphia library (27,000 volumes); of congress (16,000 volumes); of Charleston (13,000).

LIBRATION OF THE EARTH is sometimes used to denote the parallelism of the earth's axis in every part of its revolution round the sun.

LIBRATION OF THE MOON. Very nearly the same face of the moon is always turned towards the earth, it being subject to only a small change within certain limits, the spots near the edge appearing and disappearing by turns; this is called its *libration*. The moon turns about its axis in the same direction in which it revolves in its orbit. Now, the angular velocity about its axis is uniform, and it turns about its axis in the same time in which it makes a complete revolution in its orbit; if, therefore, the angular motion about the earth were also uniform, the same face of the moon would always be turned towards the earth; for, if the moon had no rotation on her axis, when she is on opposite sides of the earth, she would show different faces; but if, after she has made half a revolution in her orbit, she has also turned half round her axis, then the face, which would otherwise have been shown, will be turned behind, and the same face will appear; and thus, if the moon's angular velocity about her axis were always equal to her angular velocity in her orbit about the earth, the same side of the moon would be always towards the earth; but as the moon's angular velocity about her axis is not uniform, and her angular velocity in her orbit is not uniform, these angular velocities cannot continue always equal, and therefore the moon will sometimes show a little more of her eastern parts, and sometimes a little more of her western parts. This is called a *libration in longitude*. Also the moon's axis is not perpendicular to the plane of her orbit, and, therefore, at opposite points of her orbit, her opposite poles are turned towards the earth; therefore her poles appear and disappear by turns. This is called a *libration in latitude*. Hence nearly one half of the moon is never visible at the earth, and therefore nearly one half of its inhabitants (if it have any) never see the earth, and nearly the

other half never lose sight of it. Also, the time of its rotation about its axis being a month, the length of the lunar days and nights will be about a fortnight each. It is a very extraordinary circumstance, that the time of the moon's revolution about her axis should be equal to that in her orbit.

LIBYA, with the ancient geographers, a large part of the north of Africa, west of Egypt, which was divided into Libya exterior and interior, sometimes also into Libya Proper, Lybia Marmarica and Lybia Cyrenaica. The Greek authors sometimes comprehended all Africa under this name.

LICENSES, or FREE LETTERS, were instruments used to diminish the effect of the Berlin and Milan decrees of Napoleon, and the British order in council, which threatened the destruction of European commerce, if some exceptions had not been made by both nations. Britain decreed first, in November, 1808, that vessels of all nations, the French excepted, might be provided with letters good for one year, upon condition of importing grain into Britain; but, after 1809, licenses were given under the condition of exporting British manufactures or colonial produce. Licenses were also used by France, especially for the purpose of supplying her navy. False papers for ships were also a common use. At last, it was decided by Britain to grant licenses to all ships not French, even though they carried a French license, upon condition that one third part of the cargo should be British goods, the same portion of French cargo being also allowed. France also gave licenses (to American vessels) to export French goods, and, in return, to import colonial produce. Licenses were granted by Russia to trade with Britain, from 1811, and by Sweden, by the same trade, from 1812; but, at the fall of the famous continental system (see that article), the licenses became useless.

LICENTIATE; an academical dignity between the baccalaureate and the doctorate, and the obtaining of which is a necessary step to taking the doctor's degree. *Licentiate* also signifies the person who has received the degree. A licentiate in theology has the right of delivering theological lectures, and a licentiate in medicine the right to practice.

LICHENS; a family of plants, belonging to the Linnean class *cryptogamia*, containing about 350 known species, which are now arranged under several genera. Their substance is powdery, crustaceous, membranous, coriaceous, or even coraceous; and the form that of a horizontal frond, sometimes lobed, divided, bearing scattered tubercles and capitate warts, or branching and coralloid. They are common every where, adhering to rocks, the trunks of trees, and barren soil. On ascending mountains they are found flourishing beyond the limit of other plants, even to the very verge of perpetual snow. Many of them, fixing upon the hardest rocks by retaining moisture, facilitate their decomposition and promote the formation of soil. They are generally perennial, and grow by receiving moisture through all parts of their surface, and, though frequently desiccated, the least rain restores their freshness. Many of the species appear to be universal distributed, occurring in all parts of the globe. In the lichens of the equatorial regions and southern hemisphere have not, hitherto, been minutely examined. Several of the species are used for subsistence in time of scarcity, by the inhabitants of the northern regions. The *tripe de roche* of the Canadians, so often resorted to by the fur traders, is a lichen, somewhat resembling the *subcetraria* to which the name is derived. The reindeer moss (*nomophyces rangiferina*) is common in several of the many parts of the northern hemisphere, but it is

arctic regions, it grows in the greatest profusion, often occupying, exclusively, extensive tracts of country, covering the ground to the depth of a foot or more, and having the appearance of snow. It is celebrated as being the chief resource of the reindeer in these desolate regions. The Iceland moss (*physcia leucanica*) is also exceedingly abundant in the arctic regions, and often affords aliment to the inhabitants, either in the form of gruel or bread, which last, though not agreeable, is very nutritious. The taste is bitter, astringent, and extremely mucilaginous. It is an article of commerce, and is very frequently employed in pharmacy, in the composition of various pectoral lozenges and sirups, and is celebrated as an article of diet, in combination with milk, in coughs and pulmonary affections. The plant consists of a membranous frond, divided into lobes and *lacinae*, which are unattached, and either smooth or fringed on the margin. It is very abundant in the Alpine region of the White mountains of New Hampshire, America. Orchal (*orella tinctoria*) is still an important article of commerce, though much less used now than formerly, on account of the fugitiveness of the rich purple and rose-coloured dyes which it yields. Some of its tints, however, are capable of being fixed, and it is, besides, employed for staining marble, forming blue veins and spots. It grows on rocks, bordering on the sea, in the islands of the Mediterranean, the Azores, Canaries, Cape Verde and Bourbon. That from the Canaries is most esteemed, and is largely imported into Europe. Several other lichens afford dyes of various colours, some of which can be rendered permanent. Litmus is also obtained from a lichen. See *Litmus*.

LICHTENBERG, GEORGE CHRISTOPHER, one of the greatest natural philosophers, and wittiest writers, that Germany has produced, was born in 1742, at Ober-Ramstadt, near Darmstadt, and was the youngest of a family of eighteen children. He received from his father some instruction in physics, and went, after his death, to the academy at Darmstadt. He was strong and well formed till eight years of age; but, at this time, the effects of the carelessness of his nurse became visible, in a distortion of the spine. In 1763, he went to Göttingen, where he applied himself to astronomical observations. He made observations upon the earthquake of 1767, and observed, with Kästner, the transit of Venus over the sun's disk, June 19, 1769, as also the comets of 1770, 1771, and 1773, the orbit of which last he described, and resorted to the academy of sciences of Göttingen. He also constructed lunar charts, in which the spots are indicated in the order in which they are successively covered by the earth's shadow. In 1770, he was offered a professorship at Göttingen, which he entered upon in his twenty-eighth year. In this year he went to London. Lichtenberg ascertained by observation, in 1772 and 1773, the situations of Dover, Osnabrück, and Stade. He afterwards undertook to publish, with illustrations, the papers of Tobias Mayer, and added a lunar chart, with description of lunar spots; but only one volume appeared. He visited England again in 1774, and met upon Garrick and the English stage. He subsequently published an excellent commentary upon Hogarth's engravings. In 1778, he returned to Göttingen. From this period he lectured upon experimental philosophy. His lectures were of great value, and his apparatus was princely. He was regarded as a discoverer in physics, from his observations upon the figures developed upon electrified surfaces, which he learned to reproduce and exhibit, and which still retain his name. He also worked, with much wit, in several publications, the system of physiognomy to which Lavater had given

such currency; but he was subsequently reconciled to Lavater. Other productions, which he thought censurable, felt the lash of his wit. His taste for drawings illustrative of character, made him a great admirer of Hogarth. He, for a long time, supplied the Göttingen Souvenir with miniature drawings of the heads of Hogarth, accompanied by very witty and ingenious observations. The favourable reception of these led to the publication of a Minute Explanation of Hogarth's Plates, with perfect miniature Copies of them, by Riepenhausen, of which he published four numbers himself: the seven next to the eleventh were published by Bottiger, and the last by Bouterwek. In the last years of his life, Lichtenberg became hypochondriac and misanthropic, so that he shut himself up in his chamber, and would see no one. He died of a pulmonary inflammation, Feb. 24, 1799, aged 57. He was an original thinker, to whom no subject of a scientific character was uninteresting. Scientific spirit and poetic talent were united in him in a singular degree, and produced the most peculiar and striking results; but the highest principle of the human mind—faith in something divine—was, in his speculative moments, disregarded; and a superstitious belief in dreams, predictions and presentiments, was admitted in its stead.

LICHFIELD, or LITCHFIELD; an ancient city of England, in the county of Stafford, and a county of itself, with particular local jurisdiction, under the government of the bailiffs and magistrates. It stands on a small brook that runs into the Trent. The city is neat and well built, and consists of three or four principal streets, and some smaller ones; and is separated from the Close, which is in the county of Stafford, by a pool of running water. It is the residence of the dignitaries of the church. The cathedral is supposed to have been founded about 656, and was afterwards much enlarged and improved. It is one of the most elegant religious edifices in Great Britain, extending 400 feet in length, and 67 in breadth. In the centre rises an elegant steeple, to the height of 258 feet, and two smaller ones, at the west end, 183 feet. The interior is finished with corresponding elegance and splendour. The body of the church is spacious and lofty, supported by pillars formed of clusters of slender columns, with neat foliated capitals. It extends 213 feet in length, from the great west door to the choir, and 153 in breadth: the breadth of the side-aisles is 66 feet, and the height of the nave 60. Over the great west doors, that open into the nave, is placed a splendid circular window, constructed at the expense of James, duke of York, in the reign of Charles II. A number of interesting monuments are dispersed through the church, among them Chantrey's celebrated group of sleeping children. St Mary's chapel, now thrown open to the choir, is uncommonly beautiful and splendid. Besides the cathedral, the Close contains a variety of buildings, which, except a few houses, belong to the church. The bishop's palace is situated at the north-east corner. It is a spacious building of stone, with the date of 1687, and the arms of the bishopric, in front. Lichfield contains a free grammar school, at which were educated Addison, Wollaston, Ashmole, Garrick, and Johnson. Population, in 1831, 6499.

LICHTENSTEIN (properly, *Liechtenstein*), a sovereign principality, the smallest state of the German confederacy, is situated on the northern declivity of the Rhetian Alps (which here rise to the height of 5600 feet), and on the Rhine. It comprises an area of 53 square miles, with 5800 inhabitants, in 11 villages. Vadutz, a market-town, is the chief place. The prince has declared the Austrian code valid in

Lichtenstein. The courts of appeal are the Austrian courts. The prince furnishes a contingent of fifty-five men to the army of the confederacy. He has a voice in the sixteenth vote in the diet, and has the twenty-eighth vote in the general assembly (*plenum*). Nov. 9, 1818, he granted his principality a constitution, on the model of the constitution of the German states of Austria. We mention this, on account of the qualifying clauses of the fourth section of this instrument, which would make the electors of Lichtenstein an assembly of patriarchs. It gives the right of voting to every person who pays taxes on an estate valued at 2000 guilders, is thirty years old, of irreproachable and disinterested character, and of a peaceable disposition. The prince's income is 17,000 guilders, but he has large districts, with towns and villages, as an Austrian subject, which contain 350,000 inhabitants, and yield a revenue of 1,500,000 guilders. He has also considerable possessions in Bohemia.

LICK, or SALT LICK. A salt spring is called a *lick*, in the western parts of the United States of America, from the circumstance that the earth about it, which is impregnated with saline particles, is licked by the bison and deer.

LICTORS. Lictors, in Rome, were the public servants, who attended upon the magistrates, to fulfil their commands. Their name (*lictors*) was derived from their binding offenders hand and foot, previously to the punishment of scourging. The office was borrowed by Romulus from the Etruscans, whose chief magistrates were attended by servants, bearing axes tied up in bundles of rods, which were called *fusces*. He was himself always preceded by twelve of them. When the regal dignity was abolished at Rome, the royal pomp was retained; and, on this account, consuls, prætors, and other important officers (except the censors), were all attended by lictors. When a magistrate of high rank appeared in public, the lictors preceded him in a file, following each other. It was their duty to clear the road of the populace, that the consul, or other officer, might not be impeded in his progress; and this was effected by the cry, "The consul (or prætor, &c.) comes," "Make way for the consul." When he returned to his own house, or entered another, the lictors struck the door with their fasces. They also took care that proper respect should be shown to the person of the magistrate. A horseman who met the consul was obliged to dismount. Every one uncovered his head as he passed, left him free passage, &c. The lictors were the executioners of punishments. They were free men, but chosen from among the lowest classes, and were often freed-men of the magistrate whom they attended. The dictators were preceded by twenty-four lictors; the consuls, decemvirs and tribunes of the soldiers, by twelve; the prætors and master of the horse, by six, and the vestal virgins by one, only.

LIECHTENSTEIN. See *Lichtenstein*.

LIEGE (German, *Lüttich*; Dutch, *Luyk*), formerly a bishopric in the circle of Westphalia, was occupied by the French in 1794, ceded to them by the peace of Lunéville, and formed the department of the Ourthe. By a decree of the congress of Vienna, and a separate treaty of March 23, 1815, this country was given, as a sovereign principality, to the king of the Netherlands, and formed, until the Belgian revolution of 1830, a province of the kingdom, containing 2160 square miles, with 354,000 inhabitants, some portions of its territory having been added to other provinces. The Meuse and Ourthe water it. In the southern part, which is a continuation of the Ar-

dennes, the soil is rocky, hilly, and covered with woods. The western part is a fertile plain. Grass is not raised in quantities sufficient to supply the wants of the inhabitants, and has been partly supplanted by potatoes. Cattle and sheep are raised in great numbers. The Limburg cheeses, which are made in this province, are celebrated. It is rich in calamine, alum, iron, lime, good marble, flints, whetstone, and building-stone. The cloth and woollen manufactures are considerable, and guns and carriages are exported in large quantities. The arms of Turkey have been chiefly armed from the workshops of Liege.

Liege, the capital of the province, lies in a vale on the Meuse, at its confluence with the Ourthe. Liege was formerly fortified. There are several bridges across the river. The population is 60,000 houses, 8000. There are forty churches in the city. Lat. 50° 39' 22" N.; lon. 5° 31' 50" E. The inhabitants are chiefly Walloons who speak a corrupt French, mixed with Spanish and German. Muskets are made from the value of a crown to 500 louis d'or. There are also cannon-foundries, zinc-works, tanneries, &c. Nails are manufactured here in great quantity. A university was established at Liege (1817), which, previous to the troubles of 1830, had 350 students and several useful institutions connected with it.

LIEGNITZ, capital of the government of the same name, in Silesia, Prussia, at the confluence of the Schwarzwasser and Katsbach, the seat of a government, &c., has 9000 inhabitants, institutions for education, linen-bleacheries, &c. Frederick the Great defeated general Laudon near Liegnitz, August 15, 1760. Not far from it lies the village of Wahlstatt, from which Blücher received his title of prince, on account of the battle of the Kachert (q. v.). The former principality of Liegnitz had dukes of the Piast family. The second wife of the king of Prussia, to whom he was united by what is called a *left-handed*, or *morganatic marriage* (see *Morganatic Marriage*), November 11, 1818, bore the title of princess of Liegnitz. She was a countess von Harrach. May 26, 1826, she joined the Protestant church, having previously been a Catholic.

LIEN, in law, in its most usual acceptation, signifies "the right which one person, in certain cases, possesses of detaining property, placed in his possession, belonging to another, until some demand, which the former has, is satisfied." It is, however, an unfrequently used, whenever property, either real or personal, is charged with the payment of a debt or duty, every such charge being styled a *lien on the property*, although the latter be not in the possession of the person to whom the debt or duty is due. This second signification would open to wide a field of discussion. We shall therefore confine ourselves to the explanation of the right of detaining, which is the more technical meaning of the two. Liens are of two kinds: 1. *particular liens*, that is, where the person in possession of goods may detain them until a claim, which accrues to him from those identical goods, is satisfied; and 2. *general liens*, that is, where the person in possession may detain the goods, not only for his claim accruing from them, but also for the general balance of his account with the owners. Again, liens may be given by the common law, without any agreement between the parties; some are created by express agreement, and some by usage: which latter, indeed, implies an agreement, because, when a man enters into any business, where a particular usage is generally adopted, he is presumed to consent to be bound by that usage, even as he deals with others, he expressly protests against it.

I. The common law gives a lien to the person in possession of goods in three instances: 1. When the common law compels the members of any particular trade or business, without any option on their part, to accept employment from every person who is willing to pay a reasonable compensation, in recompense for the burden which it thus throws upon them, it allows them to detain such goods as are delivered to them in the course of their business, until the owner has satisfied any debt which may have arisen out of the transaction in which the goods were so delivered. Innkeepers, common carriers, and farriers are entitled to this species of lien; for instance, the proprietor of a coach need not give up a parcel until the carriage of it be paid for. 2. When goods are delivered to a tradesman, or any other, to expend his labour upon, he is entitled to detain those goods until he is remunerated for the labour which he so expends. Thus a tailor is not obliged to take a customer's cloth and make it into a coat, but, if he consents to make the coat, the customer cannot compel him to deliver it until he is paid for the making. The first kind seems to be included in the second, but they are kept distinct, because it is supposed that the first was, at one time, the only species of lien allowed by the common law, and that the second was a subsequent invention, adopted on equitable considerations in limitation of it. 3. When goods have been saved from the perils of the sea, the salvor may detain them until his claim for salvage is satisfied; but the finder of goods has in no other case a lien on the goods found, in respect of the trouble and expense to which the finding and preserving of them may have subjected him. All these are particular liens; and, therefore, the coach proprietor may not detain the parcel, nor may the tailor detain the coat, nor the salvor the property saved, until payment of the carriage of a former parcel, or of the price of another coat, or of salvage which accrued for saving other goods. Another rule with regard to particular liens is, that they exist only so long as the possession of the goods is retained by the person who has the lien. If he once deliver up the goods to the owner, he waves his lien, which is hereby so effectually annihilated, that it will not be revived, even if the same goods should afterwards return into his possession. Thus, if the tailor deliver the coat, and it is afterwards sent to him to be mended, he cannot then detain it as a security for the original price, but only for the cost of mending. His remedy to recover the price must be by a suit at law; and we may here remark, that a creditor can never prejudice his right of maintaining an action for his demand, by insisting on his right of detaining the goods, for the action and the lien are concurrent rights, and do not interfere with each other.

II. *General liens* are only created by express agreement, or by usage. It has been determined, at attorneys and solicitors, bankers, factors, and brokers, insurance-brokers, and some others, are, by the custom of their respective trades and professions, entitled to a lien on the property of their clients, customers and employers, for the general balance of their accounts. Thus an attorney may detain papers which have been delivered to him to assist in the conducting of one cause, as a security for the costs of other; and, if he return them to his client, and they re-again into his possession, his lien revives; for, in the case of a general lien, it matters not whether the same or different papers are delivered to the person employed, his right of detaining being the same in both instances.

**LEOU-KIEOU.** See *Loon-Choo*.

**LEUTENANT.** This word, like *captain*, and

many others, has received gradually a much narrower meaning than it had originally. Its true meaning is a *deputy*, a *substitute*, from the French *lieu* (place, post) and *tenant* (holder). A *lieutenant général du royaume* is a person invested with almost all the powers of the sovereign. Such was the count d'Artois (afterwards Charles X.) before Louis XVIII. entered France, in 1814. The duke of Orleans, before he accepted the crown as Louis-Philip, was appointed to the same office by the chamber of deputies. *Lieutenant-general* was formerly the title of a commanding general, but at present it signifies the degree above major-general. *Lieutenant-colonel* is the officer between the colonel and major. *Lieutenant*, in military language, signifies the officer next below a captain. There are first lieutenants, and second, or *sous-lieutenants*, with different pay. A lieutenant in the navy is the second officer next in command to the captain of a ship. According to the new organization of the French navy, of 1831, there are *lieutenants de vaisseau* and *lieutenants de frégate*, formerly called *enseignes de vaisseau*. The latter can command only in the absence of the former. In Britain, the *lord-lieutenant* of a county has the authority to call out the militia in case of invasion or rebellion. The governor of Ireland is also called *lord-lieutenant of Ireland*. In some British colonies, jointly under a *governor-general*, the chief magistrate of each separate colony is called *lieutenant-governor*.

**LIFE.** See *Physiology*.

**LIFE-BUOY.** The life-buoy, now commonly used in the British navy, is the invention of lieutenant Coote, of the royal navy. It consists of two hollow copper vessels connected together, each about as large as an ordinary sized pillow, and of buoyancy and capacity sufficient to support one man standing upon them. Should there be more than one person requiring support, they can lay hold of rope becketts, fitted to the buoy, and so sustain themselves. Between the two copper vessels, there stands up a hollow pole, or mast, into which is inserted, from below, an iron rod, whose lower extremity is loaded with lead, in such a manner that, when the buoy is let go, the iron slips down to a certain extent, lengthens the lever, and enables the lead at the end to act as ballast. By this means the mast is kept upright, and the buoy prevented from upsetting. The weight at the end of the rod is arranged so as to afford secure footing for two persons, should that number reach it; and there are, also, as was said before, large rope becketts, through which others can thrust their head and shoulders, till assistance is rendered. At the top of the mast is fixed a port-fire, calculated to burn about twenty minutes, or half an hour: this is ignited, most ingeniously, by the same process which lets the buoy fall into the water; so that a man, falling overboard at night, is directed to the buoy by the blaze on the top of its pole or mast, and the boat sent to rescue him also knows in what direction to pull. The method by which this excellent invention is attached to the ship, and dropped into the water in a single instant, is, perhaps, not the least ingenious part of the contrivance. The buoy is generally fixed amid-ships, over the stern, where it is held securely in its place by being strung, or threaded, as it were, on two strong perpendicular rods, fixed to the taffarel, and inserted in holes piercing the frame work of the buoy. The apparatus is kept in its place by what is called a *slip-stopper*, a sort of catch-bolt, or detent, which can be unlocked at pleasure by merely pulling a trigger; upon withdrawing the stopper, the whole machine slips along the rods, and falls at once into the ship's wake. The trigger, which unlocks the slip-stopper, is furnished with a lanyard, passing through a hole in the stern, and having at its inner

end, a large knob, marked "LIFE-BUOY;" this alone is used in the day-time. Close at hand is another wooden knob, marked "LOCK," fastened to the end of a line fixed to the trigger of a gun-lock primed with powder, and so arranged that, when the line is pulled, the port-fire is instantly ignited; while, at the same moment, the life-buoy descends, and floats merrily away, blazing like a light-house. The gunner, who has charge of the life-buoy lock, sees it freshly and carefully primed every evening at quarters, of which he makes a report to the captain. In the morning, the priming is taken out, and the lock uncocked. During the night, a man is always stationed at this part of the ship; and every half hour, when the bell strikes, he calls out "Life-Buoy!" to show that he is awake and at his post, exactly in the same manner as the look-out men abaft, on the beam and forward, call out, "Starboard quarter!" "Starboard gangway!" "Starboard bow!" and so on, completely round the ship, to prove that they are not napping. Captain Basil Hall's *Fragments of Voyages*; second series.

**LIFE-PRESERVERS.** The human body is a little lighter than an equal bulk of water, so that it naturally floats in this fluid. The mouth, however, in the case of most men lying motionless in the water, would sink below the surface, if the head were not thrown back by a muscular effort. Many persons who fall into still water, and are unable to swim, might be saved, if they had any presence of mind sufficient to preserve a proper position. The specific levity of the body, in comparison with water, makes it easy to keep the upper part of it considerably elevated above the surface of the water by attaching to the chest some buoyant substance, even though its bulk be not great; and many contrivances, called *life-preservers*, have been invented with this view. A great portion of them, however, have been found, in practice, of little or no use. One of the latest is the invention of a Mr Scheffer, in England. It consists of a hollow cylinder, formed without a seam, and perfectly air-tight, bent when distended with air and ready for use; or it is what may be termed a *cylindrical ring*, without a seam, and without a break. Of this ring, the external diameter is generally about 22½ inches, the internal diameter about 12, and the diameter of the cylinder about 5½, the dimensions varying, of course, by being specially adapted to the size of the person by whom it is designed to be employed. It contains a small stop-cock, to which an ivory pipe is fixed. Through this pipe the air is injected by the mouth, and retained by the stop-cock; the adjustment and inflation only occupying the short space of one minute. When unexpanded, it folds up into a very small compass, so as to be conveyed in the pocket; and is also very portable, its weight being but twelve ounces. Another life-preserver, invented by a gentleman from Connecticut, America, does not differ essentially from this, except that it is a straight cylinder. It is made of cloth without a seam, and rendered impervious to water by a preparation of caoutchouc; is about two feet, or two and a half feet long, and eight or ten inches in diameter; is filled like the one first described, and secured to the body by means of straps passing over the shoulders. When empty, it occupies but little room, and may even be worn by a man labouring on the deck of a vessel in danger. He can inflate it in a few moments, when he finds it necessary to trust himself to the waves.

**LIGAMENT**, in anatomy; a strong, compact substance, serving to join two bones together. A ligament is more flexible than a cartilage, not easily ruptured or torn, and does not yield, or at least yields very little, when pulled.

**LIGATURE**, in surgery, is a cord, band, or string;

or the binding any part of the body with a cord, band, fillet, &c., whether of leather, linen, or any other matter. Ligatures are used to extend or repress bones that are broken or dislocated; to tie the patients down in lithotomy and amputations; to tie upon the veins in phlebotomy, on the arteries in amputations, or in large wounds; to secure the splints that are applied to fractures; to tie up the processes of the *peritoneum*, with the spermatic vessels, in castration; and, lastly, in taking off warts or other excrescences by ligature. *Ligature* is also used to signify a kind of bandage or fillet, tied round the neck, arm, leg, or other part of the bodies of men or beasts, to divert or drive off some disease, accident, &c.

**LIGATURES**, among printers, are types consisting of two letters or characters joined together, as *ff*, *fl*, *fi*. The old editions of Greek authors are extremely full of ligatures; the ligatures of Stephen are by much the most beautiful.

**LIGHT** is that which renders objects perceptible to our sense of seeing. It is one of the most interesting subjects that fall under the contemplation of the philosopher: at the same time it must be acknowledged to be one that is as little understood, and upon which opinions are as much divided, as any of the most abstruse subjects of philosophical inquiry. Some consider light as a fluid *per se*; while others consider it merely as a principle, and attribute to it a sort of pression, or vibration propagated from the luminous body through a subtile, ethereal medium. The ancients believed it to be propagated from the sun and other luminous bodies instantaneously; but the observations of the moderns have shown that this was an erroneous hypothesis, and that light, like any other projectile, employs a certain time in passing from one part of space to another, though the velocity of its motion is truly astonishing, as has been manifested in various ways. And first, from the eclipses of Jupiter's satellites; it was observed by *Römer*, that the eclipses of those satellites happen sometimes earlier and sometimes later than the times given by the tables of them, and that the observation was before or after the computed times, according as the earth was nearer to or farther from Jupiter than the mean distance. Hence it was concluded that this circumstance depended on the distance of Jupiter from the earth and that, to account for it, we must suppose that the light is fourteen minutes in crossing the earth's orbit. The original observations have received some corrections, and it is now found that, when the earth is exactly between Jupiter and the sun, his satellites are seen eclipsed about eight minutes and a quarter sooner than they could be according to the tables; but when the earth is nearly in the opposite part of its orbit, these eclipses happen about eight minutes and a quarter later than the tables predict them. Hence, then, it is certain that the motion of light is not instantaneous, but that it takes up about 14½ minutes of time to pass over a space equal to the diameter of the earth's orbit, which is nearly 190,000,000 of miles in length, or at the rate of 200,000 miles per second—a conclusion which it may be added, is placed beyond doubt, by the observation of the stars discovered by the celebrated *astronomer* Bradley.

Upon the subject of the materiality of light, *Isaac Newton* observes, in expressing his dissent from the doctrine that light consists of particles of matter continually driven off from the sun's surface, with such enormous swiftness—"Must not the smallest portion conceivable have, with such a motion, a force equivalent to that of a twenty-four pounder discharged from a cannon? Must not the sun diminish exceedingly by such a waste of matter, and the planets, instead of drawing nearer to him, as some have feared, recede

to greater distances, through the lessened attraction? Yet these particles, with this amazing motion, will not drive before them or remove the least and slightest dust they meet with, and the sun appears to continue of his ancient dimensions, and his attendants move in their ancient orbits." He therefore conjectures that all the phenomena of light may be more properly solved, by supposing all space filled with a subtile elastic fluid, not visible when at rest, but which, by its vibrations, affects that fine sense in the eye, as those of the air affect the grosser organs of the ear; and even that different degrees of vibration of this medium may cause the appearances of different colours. And the celebrated Euler has maintained the same hypothesis, urging some further objections to the materiality of light, besides those of doctor Franklin above alluded to.

Newton first discovered that certain bodies exercise on light a peculiar attractive force. When a ray passes obliquely from air into any transparent liquid or solid surface, it undergoes, at its entrance, an angular flexure, which is called *refraction*. The variation of this departure from the rectilinear path for any particular substance, depends on the obliquity of the ray to the refracting surface; so that the sine of the angle of refraction is to that of the angle of incidence in a constant ratio. Newton, having found that unctuous or inflammable bodies occasioned a greater deviation in the luminous rays than their attractive mass, or density, gave reason to expect, conjectured, that both the diamond and water contained combustible matter—a conjecture which was verified by subsequent discovery. Doctor Wollaston invented a very ingenious apparatus, in which, by means of a rectangular prism of flint glass, the index of refraction of each substance is read off at once by a vernier, the three sides of a movable triangle performing the operations of reduction in a very compendious manner. (*Phil. Trans.*, 1802.) But transparent media occasion not merely a certain flexure of the white sunbeam, called the *mean refraction*: they likewise decompose it into its constituent colours. This effect is called *dispersion*. Now, the mean refractive and dispersive powers of bodies are not proportional to each other. In some refracting media, the mean angle of refraction is smaller, whilst the angle of dispersion is larger. From the refractive power of bodies, we may, in many cases, infer their chemical constitution. For discovering the purity of essential oils, an examination with doctor Wollaston's instrument is of great utility, on account of the smallness of the quantity requisite for trial. This idea of doctor Wollaston has been happily prosecuted by M. Biot with regard to gaseous compounds; and we now have accurate tables of the refractive power of all transparent gaseous, liquid, and solid bodies. Carburet of sulphur exceeds all fluid substances in refractive power, surpassing even flint glass, topaz, and tourmalin; and in dispersive power, it exceeds every fluid substance, except oil of assa. Rays of light, in traversing the greater number of crystallized bodies, are commonly split into two pencils; one of which, called the *ordinary ray*, follows the common laws of refraction, agreeably to the tables alluded to, whilst the other, called the *extraordinary ray*, obeys very different laws. This phenomenon is produced in all transparent crystals, whose primitive form is neither a cube nor a regular octahedron. The division of the beam is reuter or less, according to the nature of the crystal, and the direction in which it is cut; but, of all known substances, that which produces this phenomenon in the most striking manner, is the crystallized carbonate of lime, called *Iceland spar*. If the white sunbeam, admitted through a small hole of a window-

shutter into a darkened room, be made to pass through a triangular prism of glass, it will be divided into a number of splendid colours, which may be thrown upon a sheet of paper. Newton ascertained that if this coloured image, or *spectrum*, as it is called, be divided into 360 parts, the red will occupy forty-five, the orange twenty-seven, the yellow forty-eight, the green sixty, the blue sixty, the indigo forty, and the violet eighty. The red rays, being least bent by the prism from the direction of the white beam, are said to be least refracted, or the least refrangible, while the violet rays, being always at the other extremity of the spectrum, are called the most refrangible. If these differently coloured rays of light be now concentrated on one spot, by a lens, they will reproduce colourless light. Newton ascribes the different colours of bodies to their power of absorbing all the primitive colours, except the peculiar one which they reflect, and of which colour they therefore appear to our eye. The different coloured rays possess very different powers of illumination. The lightest green, or deepest yellow, which are near the centre, throw more light on a printed page than any of the rays towards either side of the spectrum. The rays of the prismatic spectrum differ from one another also in their heating power, as was first noticed by Herschel. In viewing the sun, by means of large telescopes, through differently coloured darkening glasses, he sometimes experienced a strong heat, attended with very little light, and, at other times, he had a strong light with a little heat. This observation led to his well known researches upon this subject, from which he concluded that the maximum heat is just without the spectrum, beyond the red ray. Others have found the greatest heat in the red ray itself; but the recent observations of M. Seebeck have shown that the point of greatest heat was variable, according to the kind of prism which was employed for refracting the rays. When a prism of fine flint glass is used, the greatest heat is constantly beyond the red; when a prism of crown glass, the greatest heat is in the red itself. It has long been known, that the solar light is capable of producing powerful chemical changes. One of the most striking instances of it is its power of darkening the white chloride of silver—an effect which takes place slowly in the diffused light of day, but in the course of two or three minutes by exposure to the sunbeam. This effect was formerly attributed to the influence of the luminous rays; but it appears, from the observations of Ritter and Wollaston, that it is owing to the presence of certain rays, that excite neither heat nor light, and which, from their peculiar agency, are termed *chemical rays*. It is found that the greatest chemical action is excited just beyond the violet ray of the prismatic spectrum, and that the spot next in energy is occupied by the violet ray itself, and that the property gradually diminishes as we advance to the green, beyond which it seems wholly wanting. The sunbeams, in traversing a coloured glass, produce similar effects to those caused by the differently coloured portions of the spectrum. Thus the chloride of silver acquires a black tint behind a blue or violet glass, but does not blacken behind a red or orange glass; on the other hand, it becomes red behind a red glass, and that much more quickly than even in the solar spectrum. Light produced by coal and oil gases, or by olefant gas, even when concentrated so as to produce a sensible degree of heat, was found, by Mr Brande, to occasion no change in the colour of muriate of silver, nor in mixtures of chlorine and hydrogen; while the light emitted by electrized charcoal speedily affected the muriate, and caused these gases to unite, and sometimes with explosion.

The concentrated light of the moon, like that of the gases, produced no change. The importance of light to plants is well known: deprived of it, they become white, and contain an excess of saccharine and aqueous particles: and flowers owe the variety and intensity of their hues to the influence of the solar beams. Even animals require the presence of the rays of the sun, and their colours seem materially to depend upon the chemical influence of these rays. A comparison between the polar and tropical animals, and between the parts of their bodies exposed, and those not exposed to light, shows the correctness of this opinion. (For an account of the physical affections, and other chemical effects of light, see *Optics, Phosphorescence, and Polarization of Light.*)

LIGHT, DIFFUSION OF ITS PARTICLES. See *Divisibility*.

LIGHT CAVALRY, or HORSE. See *Cavalry*.

LIGHTER; a large, open, flat-bottomed vessel, employed to carry goods to or from a ship.

LIGHTFOOT, JOHN, a learned English divine, born in Staffordshire, in 1602, and received his education at Christ-church, Cambridge. He made extraordinary advances in the Greek and Latin languages, and became curate of Norton-under-Hales. Sir Rowland Cotton made Mr Lightfoot his chaplain, and took him into his house, where he applied himself to Hebrew with singular assiduity and success. In 1629, he printed his first work, entitled *Erubhim*, or Miscellanies, Christian and Judaical, which he dedicated to Sir Rowland Cotton, who presented him to the vicarage of Ashley, in Staffordshire. Here he resided until his appointment as one of the parliamentary assembly of divines rendered it necessary for him to remove to London. He warmly pressed the speedy settlement of the church, in the presbyterian form. In 1655, he became vice-chancellor of Cambridge, and zealously promoted the Polyglot Bible. After the restoration, he was appointed one of the assistants at the Savoy conference, where he, however, attended but once or twice, giving all his attention to the completion of his *Harmony*. He died Dec. 6, 1675. The works of Dr Lightfoot, who, for rabbinical learning, has had few equals, were printed in 1684, in 2 vols., folio; and again, with additions, at Amsterdam, in 1686; and by Leusden, at Utrecht, 1699, in 3 vols. An octavo volume of his remains was also published by Strype, which contains some curious particulars of his private life.

LIGHTHOUSES were in use with the ancients. The towers of Sestos and Abydos, the colossus of Rhodes, the well-known tower on the island of Pharos, off Alexandria, are examples. Suetonius also mentions a lofty tower at Ostia, and another on the coast of Batavia, erected for the purpose of guiding the mariner by their light. In lighting a great extent of coast, it becomes necessary to provide for the distribution of the lighthouses in such a manner that they may be readily distinguished from each other, and, at the same time, so disposed as not to leave vessels without some point by which to direct their course; and, in constructing each member of the series, care should be taken to provide for a sufficient brilliancy of light, and for means of distinguishing each lighthouse from every other, as well as from other lights on shore or in ships, or in the heavens. The best constructed lighthouses, in Great Britain, are fitted up with parabolic reflectors, consisting of a circular sheet of copper, plated with silver, in the proportion of six ounces to each pound of copper, and formed into a parabolic curve, by the assistance of a gauge, by a very nice process of hammering. The reflector, thus shaped, is then polished

with the hand. An Argand lamp is placed in the focus of the paraboloidal surface, and the oil is supplied by the lamp behind. But the disadvantages of this mode are acknowledged; such as the loss of light, partly from its absorption by the reflector and partly from the collision of the rays; the imperfection of increasing the intensity of the light in dark and hazy weather; the difficulty of forming dazzling lights, &c. The important invention of the polygonal lenses, in which refraction is employed instead of reflection, seems, therefore, likely to supersede the use of reflectors. This subject is treated by Brewster (*Transactions of the Royal Society of Edinburgh*, vol. xi.), and by M. Fresnel, in a paper read before the academy of sciences at Paris—*Sur un nouveau Système d'Eclairage des Phares* (1822)—and the imperfections of the parabolic reflector, and the superiority of the polygonal lenses over others, are explained. Another important problem in the construction of distinguishing lights, so that the mariner may not be deceived in taking one light-house for another. Single and double stationary lights, or lights disposed in different forms, were first employed; revolving lights were next adopted, which appeared and disappeared at intervals, and these are sometimes exhibited double or triple. The lights may be so disposed as only to illuminate the safe channel. Difference of colour is sometimes made use of as a distinction. It sometimes becomes desirable, as in hazy weather, to produce a very intense light. A plan was proposed, to effect the object, by lieutenant Drummond (*Philosophical Trans.* 1826), by directing upon a ball of chalk, a quarter of an inch in diameter, three alcoholic flames by means of a stream of oxygen. The employment of gas, in lighthouses, has also been recommended.

*Floating Light* differs from the preceding, by its being erected on board a vessel, which is always moored upon a sand or shallow, to warn ships against approaching it.

A select committee of the house of commons was appointed early in the year 1834 to inquire into the present state of British lighthouses; and the following are the views of the directors as stated in their petitions to parliament, and as recorded in the minutes of the committee:—1. That all private claims in lighthouse property should cease. 2. The exclusive appropriation to lighthouse purposes of all funds collected in name of lightmoney. 3. Collection to be limited to the amount required for lights. 4. No exemptions from payment of dues by vessels using the lights; and that steamers, coasting and fishing vessels, be taxed at less rates than other vessels. 5. Collection of the dues in the hands of government. 6. A consolidation of the boards, and a uniform scale of rates applicable to the whole United Kingdom—and 7. A reduction of expenses and rates generally. In addition to the above suggestions, the directors recommended the trial of an experiment in the hands of government to prove the merits of the lens system of illuminating lighthouses, as now extensively practiced in France, in comparison with that of parabolic reflectors, and hitherto in this country. The experiments at Col-lane Point were not such as to put this long-disputed matter fully at rest. On three occasions lights were applied to the foci of individual lenses only, without the assisting apparatus of subsidiary lenses and mirrors, as described in the work of M. Fresnel. From a correspondence entered into with scientific men in this country and France, and likewise from the obvious leaning of the different boards to the old system, the directors were convinced of the expediency of conducting an experiment in the hands of neutral persons; and subsequent compe-

sons between the systems which have been carried on in France have fully justified this measure. Successful experiments have likewise been made on the application of the oxy-hydrogen gas light upon quicklime, as a substitute for that at present employed in lighthouses.

**LIGHT INFANTRY** ; a name given to all foot-soldiers not intended to fight in column, or, at least, to fight chiefly as sharp-shooters. They are, in some armies, the opposite to *grenadiers*. However, *light-infantry* is not a distinguishing name, according to the present organization of armies. See *Infantry*, *Trouilleurs*, and *Grenadier*.

**LIGHTNING.** See *Electricity*.

**LIGHTNING-ROD.** See *Conductor*.

**LIGHTWOOD** ; a name given, in America, to the knots and other resinous parts of pine trees.

**LIGNE, CHARLES JOSEPH**, prince de, a brave soldier and talented author, was born at Brussels, in 1735. The prince de Ligne devoted his early years to the study of the classics and the science of war. In 1755, he entered the Austrian service, and served as captain till 1758. In 1759, he was made colonel. At the end of the war, he was stationed in the Netherlands, with the rank of major-general, and the count d'Artois invited him to the French court, where his society was generally sought, and he was admitted into the privacy of the royal family. He visited England and Italy. In 1770, he was present at the meeting of Frederic the Great with Joseph II., in Silesia. On a visit to Petersburg, he received great honours from the empress. His conduct in the Netherlands had made him very popular. He accompanied the empress Catharine to Cherson. At the commencement of the war with the Turks, he was Austrian ambassador to the Russian army; afterwards, he commanded part of the army which besieged and took Belgrade. He died Dec. 13, 1814. He has given historical accounts of several battles in which he took an active part. His knowledge, experience, activity, and acute observation, appear in his numerous writings, of which thirty volumes were published, at different periods, on a variety of subjects, in verse and prose, in the French language. Madame de Staël edited a selection from them. He gives much information on the leading persons and events of his time, in an amusing and instructive manner.

**LIGNUMVITÆ.** See *Guaiacum*.

**LIGNY, BATTLE OF**, on June 16, 1815. See *Quatrebras*, and *Waterloo*.

**LIGUORI, ALPHONSO MARIA DE**, founder of the sect called *Ligorists*, or *Redemptorists*, was born at Naples, Sept. 26, 1696. He was originally a lawyer; but some unpleasant circumstances in his profession induced him to become a priest, in 1722. He soon joined the Congregation for the Propagation of the Faith, which had been instituted in Naples, and occupied himself as a missionary in the instruction of the ignorant peasantry. In 1732, he founded a monastery in the hermitage of St Mary, at Villacale (in the Principato Citra), with the approbation of the pope, the members of which were called the *Order of the most holy Redeemer*, and were to be employed in the instruction of the people. This order soon extended over both Sicilies. The first houses belonging to it were at Salerno, Coma, Nocera, and Bovino. For a long time this order, so much like the Jesuits, was unknown beyond the limits of Italy, till, in 1811, they took possession of the suppressed Carthusian monastery at Val-Saint, in the diocese of Friburg, the occupants of which (some Jansenists) had been expelled. They subsequently secured in the Austrian dominions, and even in the papal, where they now have a rich establishment.

**Liguori** was, in 1762, appointed bishop of Santa Agata de' Gotici (in the Principato Ultra), by Clement XIII., from which office he was released by Pius VI., in 1775, at his own request, being old, sickly, and so exhausted by fasting and penance, that he was no longer able to perform the duties of his office. He retired to the chief foundation of his order, at Nocera de' Pagani, and died there, Aug. 1, 1787, at the advanced age of ninety years. Since 1816, his name has been enrolled in the Romish calendar of saints. His writings, which are of an ascetic character, have appeared, partly at Naples, and partly at Venice.

**LIGURIA**, with the Romans, was that portion of the north of Italy, extending along the Mediterranean, from the borders of France to the city of Leghorn, and bounded, on the north, by the river Po. In 1797, the aristocratic republic of Genoa received from Bonaparte a democratic constitution, under the appellation of the *Ligurian republic*. This republic ceased to exist in 1805, when the emperor incorporated it with France. Since 1814, it has formed part of the kingdom of Sardinia.

**LILAC** (*syringa*). This beautiful and familiar shrub, the ornament of our gardens, is a native of Persia and the surrounding countries. It belongs to the *diandria monogynia* of Linnæus, and to the natural family *jasminea*, in which are included the olive, the privet, and the jasmine. The corolla is funnel-shaped, and divided into four segments; the leaves are opposite; and the flowers are agreeably scented, and disposed in large pyramidal racemes, of a bluish or purplish colour. It is of easy culture. Three other species of *syringa* are known.

**LILBURNE, JOHN**, a republican, during the time of Charles I. and Cromwell, was born in 1618, and placed with a clothier in London. Of a bold, unquiet, and forward temper, one of his first exploits was to summon his master before the city chamberlain for ill usage. He employed his leisure in studying the religious systems and controversies of the time; and the Book of Martyrs, in particular, inspired him with an enthusiastic passion for encountering all sorts of danger in the cause of truth. Dr Bastwick, then under star-chamber prosecution, employed him to get anti-episcopal strictures printed in Holland. On his return, he employed himself in similar occupations, but, being betrayed by an associate, he was tried before the star-chamber, where his deportment was so firm that he acquired the appellation of *free born John*. He was doomed to receive 500 lashes, and stand in the pillory, which sentence was executed, in April, 1638, with great severity. On the meeting of the long parliament, a vote passed the house of commons, pronouncing the sentence against Mr Lilburne barbarous and illegal, and that reparation should be made to him for his sufferings and losses. He then served in the parliamentary army. Dislike to the measures of Fairfax and Cromwell, induced him soon after to lay down his sword, but it was only to take up the pen against all whose political conduct offended him. Being committed to Newgate for contempt, when brought before the house of lords for a libel on the earl of Manchester, he contrived, while thus immured, to publish pamphlets in rapid succession, in which he virulently assailed his enemies, and even made a charge of high treason against Cromwell and Ireton. For this he was ordered to be tried for seditious practices; but so active and numerous were his friends among the people, that, in 1648, the house of commons thought fit to discharge him, and make an order for reparation for his sufferings. At the time of the king's death, he busied himself in drawing up a new constitution, and boldly maintained the rights of the people against the army. So dangerous did he

appear to Cromwell and his council, that he was again committed for high treason, but, being tried before a special committee, the jury boldly acquitted him. A new offence which he gave the parliament, induced that body to pass a heavy fine on him, with an order to quit the country; on which he retired to Holland, until it was dissolved, when he used all his interest to gain a passport, but, not succeeding, he ventured home without one. Being apprehended, he was again committed to Newgate, and once more tried at the Old Bailey, where he defended himself so ably that he was once more acquitted. He then settled at Eltham, in Kent, became a Quaker, and preached at the meetings of that body at Woolwich, until his death in 1657, at the early age of thirty-nine.

LILLE, COMTE DE; the name which Monsieur (comte de Provence, afterwards Louis XVIII.) adopted when he emigrated, during the life of Louis XVI. He was styled thus also by the French imperial government, and in the *Moniteur*.

LILLO, GEORGE, an English tragic poet, born 1693, in London. He was by trade a jeweller, but, notwithstanding his attention to business, he dedicated a considerable portion of his time to the cultivation of the drama. Fielding, the author of Tom Jones, himself a dramatist, and the contemporary and personal friend of Lillo, bears strong testimony to the integrity of his heart, as well as to the excellence of his social qualities. An edition of his plays was published, in 1775, by Davies, in two volumes, 12mo. The principal are George Barnwell, or the London Prentice, a tragedy founded on an incident in domestic life, said to have taken place at Camberwell (this play, till within these few years, it was always customary to represent on lord mayor's day); Fatal Curiosity, also said to be founded in fact; Arden of Feversham, which was certainly so; and Elmeric.

LILLY, JOHN, a dramatic writer, born about 1553, studied at Oxford and Cambridge. He attempted to reform and purify the English language in two fantastic productions entitled Euphuës and his England (1580), and Euphuës and his Anatomy of Wit (1581), which met with great success. A specimen of Euphuism may be seen in the character of Sir Piercie Shafton in the Monastery of Sir Walter Scott. Lilly was also the author of a famous pamphlet against Martin Marprelate and his party, entitled Pappé with a Hatchet, published about 1589, and attributed to Nashe. See Warton's *Hist. of English Poetry*; *Ellis's Specimens*.

LILLY, WILLIAM, a famous English astrologer, born at Diseworth, in Leicestershire, in 1602, went early to London, where his necessities obliged him to article himself as servant to a mantua-maker, in St Clement Danes. In 1624, he became book-keeper to a tradesman who could not write, on whose death he married his widow, with a fortune of £1000. In 1632, he turned his attention to astrology; and he gave the public a specimen of his skill, by an assurance, in 1633, that the king had chosen an unlucky horoscope for his coronation in Scotland. About this time, he procured a manuscript copy of a book by Cornelius Agrippa, entitled *Ars notoria*, from which he imbibed the doctrine of the magic circle, and invocation of demons. In the same year, 1634, he was allowed, by the dean of Westminster, to assist David Ramsay, the king's clock-maker, in search of a hidden treasure in Westminster abbey, another associate being found in one John Scot, who pretended to understand the mystery of migers' divining rods. These three worthies accordingly made the experiment on the night appointed, and, after digging up a coffin to no purpose, they were frightened from the place by a violent storm, which Lilly, in the sequel,

attributed to demons, whom he had found means to dismiss. In 1644, he published his *Mirreours Astronomicæ*, which he continued, annually, until his death. Having acquired the friendship of Balgode V. a lock, he devoted himself to the interests of the parliament, although he occasionally varied his predictions, in order the more easily to impose on the credulity of the age. In the year 1648, Lilly and Booker, another astrologer, were sent to the camp at Colchester, to encourage the soldiers by their predictions; and such was his reputation, that he was rewarded for his various services (one of which was obtaining secret intelligence from France) with a pension of £100 per annum. About this time, he was public lectures on astrology, and succeeded so well, that he was enabled to lay out £2000 in brick-rents at Horsham. In 1650, such was the quest of the age, he received the present of a golden crown from the king of Sweden, whom he had assisted with great respect in his almanac. On the restoration, Lilly was taken into custody by order of parliament, as one of the depositaries of the secrets of the republicans, and examined concerning the persons who beheaded the king, when he declared that he had been informed that cornet Joyce acted as the executioner. A short time after, he was set at liberty under the great seal, and retired to Horsham. In 1666, some of the members, suspecting, from the hieroglyphic to his almanac, that he might know something of the causes of the great fire which followed its publication, had him sent for to a committee of inquiry, when he asserted that he had certainly foreseen the event, but could say nothing as to its cause. His life, lately republished, is a very containing production, steering, as he does, between truth and falsehood, and seldom indulging in more of the latter than is necessary to support his character as an astrologer.

LILY; a magnificent genus of plants belongs to the *hexandria monogynia* of Linnaeus. The root is a scaly bulb; the leaves simple, scattered, or verticillate; the stem herbaceous, simple, and branched at the summit, very large and elegantly fringed flowers. The corolla is campanulate, and consists of six petals, which are often reflexed at the extremity. Among the most beautiful of the species, and several of all our garden plants, are the *Alisma canadense*, or common white lily; *L. martagon*, or Turk's cap; and *L. tigrinum*—all indigenous to Europe. The best American species is the *L. superbum*, which grows in marshes, to the height of six or eight feet, bears reflexed orange flowers spotted with black, which, when numerous on the same stem, make a splendid appearance.

The lily has always held a prominent place in emblematic language. In the middle ages, and in modern times, the white lily has been the emblem of chastity. Hence the Virgin Mary is often represented with a lily in her hand, or by her side. Garcia, the sixth king of Navarre established an order of the lily in 1048, in honour of the Virgin, because his picture had been found on a lily at Naxos, the same residence. In the beginning of the fifteenth century, Ferdinand I. of Arragon founded an order of the lily or flower-pots, the knights of which wore a double chain, consisting of flower-pots filled with white lilies. The lily, or, rather, the *flor-de-lis*, as it was known, is the emblem of the Bourbons, and of many other families. The form is well known, and there are various opinions respecting the origin of the emblem. Some think that the figures originally represented the heads of balberdes, which they so truly much resemble. Some take them for the leaves of the iris, which grow on the river Lira. They have even been taken for bees, or for snakes. The

were adopted, in 1179, by Louis VII. Philip-Augustus first used them on the royal seals. The settled use of three *fleurs-de-lis* began with Charles VI. When the count d'Artois, afterwards Charles X., entered France, in 1814, the lily became a party emblem. The adherents of the Bourbons wore a lily in the button-hole, suspended by a white riband. The French government subsequently distributed them with much profusion, on various occasions; as to pupils who appeared well at public examinations. After the battle of Waterloo, Louis XVIII. offered Blücher to give the lily to every Prussian soldier; but he declined the honour. During the revolution of 1830, the lily was not attacked, as the memory of Louis the XVIII. was respected; but when the Carlists publicly celebrated the day of baptism of the duke of Bourdeaux, the people, indignant at such a scene, destroyed the lily wherever it could be found. The government (Casimir Perrier being prime minister) ordered all the crosses and the lilies to be removed from the public edifices, &c., though it had just before been in contemplation to introduce the *fleurs-de-lis* upon the tricolored banners.

LIMA, the capital of the republic of Peru, formerly called *Ciudad de los Reyes* (city of kings), is situated on the river Rimac, from which its present name is derived by a corrupt pronunciation, about ten miles from the Pacific ocean; lon. 77° 7' W.; lat. 12° 2' S.; population, according to Caldcleugh (*Travels in South America*), in 1824, 70,000; according to Stewart, who visited it in 1829, 50,000. It is about 700 feet above the level of the sea, and presents a beautiful appearance from Callao, its port. The entrance is by a beautiful avenue, or public walk, called the *alameda*, at the end of which was a handsome gate, now in ruins. Pizarro, in laying out the city, distributed the spaces for the houses into quarters, of 150 *varas*, or Spanish yards. The streets are broad, and uniformly intersect each other at right angles, running either from north to south or from east to west. Small streams of water, conducted from the river above the town, and arched over, contribute to its cleanliness. On the opposite side of the river, connected with the city by a bridge, is the suburb of *St. Lázaro*. In consequence of the frequency of the earthquakes by which Lima has suffered, the houses are seldom raised more than two stories, and are commonly built of wood, with flat roofs, from which construction no inconvenience arises, in a country where rain is unknown. The houses of the rich are built in a Moorish style, introduced from Spain. They consist of a square pile, of the height above-mentioned, enclosing a quadrangular court, which is surrounded with *piazas*, and sometimes contains a second, or even third inner court. The *Plaza*, or great square, in the centre of the city, is surrounded partly with shops, and partly with public buildings, among which are the cathedral, and the government, once the vice-regal palace, in which are shown the hall of assassination, where Pizarro was assassinated, and the hall of independence. The riches which have been lavished on the cathedral are almost beyond belief, any where but in a city which once paved street with ingots of silver, in honour of a new *cerco*. The *cabildo*, or city-house, built in the *hinese* style, the archiepiscopal palace, the mint, the palace of the inquisition (part of which is now occupied as a national museum), and the convent of the Franciscans, said to cover an eighth of the whole city, and which Mr Stewart found almost deserted, are worthy of notice. Previously to the late changes, the number of monks in Lima was reckoned at 1200, of which they are now very few. There are fourteen convents for women, and a number of *casas de ejercicios*, into which ladies retire for two or three weeks,

to perform various acts of pious penance. A university was founded at Lima in 1551, which obtained from the crown of Spain, the same privileges as that of Salamanca. The higher classes of the inhabitants are generally well educated, and the women are celebrated for their vivacity and beauty. Both sexes smoke; and this practice is excused, under the pretence that it is rendered necessary by the mists and drizzle (called, by sailors, *Peruvian dew*), which prevail at certain seasons. The manners of the people are so loose as to be proverbial in that part of the world. Music, bull-fights, and cards are the principal amusements; dancing, which is a favourite in many of the southern republics, not being popular with the *Limanians*. The Spaniards of Lima are at present almost all Creoles, the Chapetones, or European Spaniards, having left the country during the troubles. In 1824, there were 15,000 slaves in the city; but the new Peruvian constitution of 1828 abolished slavery. Lima has been repeatedly laid in ruins by earthquakes, more than twenty of which it has experienced since 1582. The most destructive were those in 1586, 1630, 1665, 1678, when a great part of the city was totally destroyed; those in 1687, 1746, when not more than twenty houses out of 3000 were left standing, and of twenty-three ships in the harbour of Callao, nineteen were sunk; those in 1764, 1822, and 1828, the two latter of which were very destructive. For the political events of which Lima has recently been the theatre, see *La Mar*, and *Peru*.

LIMB; the outermost border, or graduated edge of a quadrant, astrolabe, or such like mathematical instrument. The word is also used for the arch of the primitive circle, in any projection of the sphere *in plano*. *Limb* also signifies the outermost border or edge of the sun and moon; as the upper limb or edge, the lower limb, the preceding limb, or side, the following limb.

LIMBO (from the Latin *limbus*, edge, border) signifies, in the Roman Catholic theology, the place on the borders of hell, where the patriarchs remained, until the advent of Christ, who, before his resurrection, appeared to them, and opened the doors of heaven for them. It is not a dogma of the church, but is universally adopted by the Roman Catholics. The word *limbus* is neither found in the Bible, nor in the ancient fathers of the church; yet, as St Paul says that Christ descended to the lower parts of the earth (*Ephes.*, c. 4, v. 9), it is concluded that good and bad were there; and as the parable of the rich man says, that, between Abraham and Lazarus and the rich man, a great gulf was fixed, it is concluded that the good in those regions were not only not tormented, but were separated from the wicked. This *limbo* is called *limbus patrum*. Some theologians adopt a *limbus infantum*, where those infants, who died without being baptized, go; but those who follow St Augustine do not allow this separation of them from the damned, though they do not believe that they are tormented like the latter. It is not known when the word *limbus* first came into use; but, as *inferi* (hell) seemed to convey the idea of eternal damnation as a punishment, a milder term was adopted. Dante, in his great poem, allows the virtuous heathens to dwell in the *limbus*: thus he finds Socrates there.

*Limbo*, figuratively, means any place of confinement or restraint. Milton's *limbo*—"large and round, since called the paradise of fools, to few unknown"—is borrowed from the *limbus* of the scholastic theologians, and Ariosto's receptacle of lost things.

LIMBURG; the name of several places and provinces, of which we shall only mention the province

of the Netherlands, containing 1,600 square miles, and 293,000 inhabitants, chiefly Catholics. The Walloon, Flemish, Dutch, and German languages are spoken. The principal river is the Meuse. Maastricht is the capital. The celebrated Limburg cheese is made at Limburg, a place in the circle of Verviers, province of Liege.

**LIME, or LINDEN (*tilia*).** The species of linden are large trees, with alternate, simple, and cordate leaves, and flowers disposed on a common peduncle, which is inserted in the middle of a foliaceous bract. The American lime, or bass-wood, is a large and beautiful tree, inhabiting Canada and the northern parts of the Union, and very abundant on the borders of lakes Erie and Ontario. The leaves are cordate, acuminate, serrate, and smooth. The flowers are yellowish, supported on long, pendulous peduncles, and add much to the beauty of the tree. The wood is white and soft, and is used for a few unimportant purposes. The wood of the European lime, though light and soft, is smooth, close-grained, and much used by carvers and turners. It is in great demand for the boards of leather-cutters, and makes excellent charcoal for gunpowder, and for painters. In some countries, the fibrous, inner bark is separated by soaking in water, and manufactured into fishing-nets, mats, shoes, and clothing; and the cordage made from it is said to be remarkably strong and elastic. The wood is sometimes cut into thin strips, and used in the manufacture of chip hats, which resemble those made of straw.

**LIME.** This earth, well known in its most important properties, from the remotest antiquity, exists in great abundance in nature. In treating of it in the present article, we shall first describe its chemical properties, and afterwards speak of its natural combinations with the acids, or of the minerals to which it gives rise. Lime is obtained with most facility from the native carbonate, from which, by a strong heat, the carbonic acid may be expelled. This process is conducted on a large scale with the different varieties of limestone, which are calcined or burned, in order to obtain the caustic earth, or *quicklime*, as it is called. The lime thus obtained, however, is rarely pure enough for chemical purposes. The chemist, therefore, when he would obtain a very perfect article, calcines transparent crystals of carbonate of lime, or prepares it from solution, in the following manner. Marble or chalk is dissolved in diluted muriatic acid, leaving an excess of lime undissolved; ammonia is added, which precipitates any alumine or magnesia. The filtered solution is then decomposed by carbonate of potash, and the carbonate of lime, being washed with water and dried, is decomposed by a strong heat. The lime thus obtained is a soft, white substance, of the specific gravity of 2.3. It requires an intense degree of heat for its fusion, which is effected only by the galvanic current, by the compound blowpipe, or by a stream of oxygen gas, directed through the flame of an alcohol lamp. The light it emits, during fusion, is the strongest the chemist can produce; and it has, accordingly, been employed for a signal light, and for facilitating the observation of distant stations, in geodetical operations. Its taste is caustic, astringent and alkaline. It is soluble in 450 parts of water, according to Sir H. Davy; and in 760 parts according to other chemists. The solubility is not increased by heat. If a little water only be sprinkled on new-burned lime, it is rapidly absorbed, with the evolution of much heat and vapour. This constitutes the phenomenon of slacking. The heat proceeds from the consolidation of the liquid water into the lime, forming a *hydrate*, as slacked lime is now called. It is a compound of 3.5 parts of lime with 1.25 of water,

or very nearly 3 to 1. The water may be expelled by a red heat.

Lime-water is astringent, and somewhat acid to the taste. It renders vegetable blues green; yellow, brown; and restores to reddened limes its usual purple colour. When lime-water stands exposed to the air, it gradually attracts carbonic acid and becomes an insoluble carbonate, while the water remains pure. If lime-water be placed in a capsule under an exhausted receiver, which also contains a saucer of concentrated sulphuric acid, the water will be gradually withdrawn from the lime, which will concrete into small six-sided prisms. Lime is subjected to the action of galvanism, in high consequence, as testified by Sir H. Davy satisfactory evidence of its compound nature. It was discovered, in common with the other earths, to consist of a metallic base, which he denominated *calcium*, and oxygen. The oxides were obtained, in these experiments, in the form of an amalgamation with mercury. On exposing the amalgam to the air or to water, oxygen was absorbed, and lime re-produced. In an experiment designed to obtain the base in an insulated state, by distilling quicksilver from it, the tube broke while warm, at the moment that the air entered, the metal still had the colour and lustre of silver, took fire, and was burnt with an intense white light. Lime is said to be supposed, combined with sulphur and with phosphorus; but it rather appears that it is in lime or that unites with these inflammables. The substance of calcium is formed by heating sulphur with lime in a covered crucible. It is of a reddish-yellow colour. When thrown into water, mutual decomposition takes place, and a sulphureted hydro-sulphure, of a green colour, with a fetid odour, is produced. Phosphuret of calcium, or phosphuret of lime, as it has usually been called, is obtained in the following manner: a few pieces of phosphorus are placed at the bottom of a glass tube, which is then filled with small pieces of lime. The part of the tube where the lime is heated red-hot; and the phosphorus is then sublimed by heat. Its vapour, passing over the lime, decomposes it, and a reddish coloured phosphuret of calcium is formed. This substance is remarkable for decomposing water, whenever it is dropped into it, causing an immediate production of phosphureted hydrogen, which takes fire at the surface of the water. The lime is heated strongly in contact with chlorine, oxygen is expelled, and the chlorine is absorbed. For every two parts in volume of chlorine that disappear, one of oxygen is obtained. When liquid water is lime is evaporated to dryness, and ignited, it forms the same substance, which is the chloride of calcium. It is a semi-transparent, crystalline substance; fuses at a strong red heat; a non-conductor of electricity; has a very bitter taste; rapidly absorbs water from the atmosphere, and is hence often employed in chemical experiments, to deprive gases of any hygrometric vapour existing in them.

Chlorine also combines directly with lime, forming the very important substance used in bleaching, formerly under the name of *arymaria* of lime, but at present, and more correctly, called *chloride of lime*. It is formed by passing chlorine gas over slacked lime. A great variety of apparatus has been, at different times, contrived for favouring the combination of chlorine with slacked lime, for the purposes of commerce. In the opinion of doctor Lavoisier, the following construction for subjecting lime-powder to chlorine is the best: It consists of a large chamber eight or nine feet high, built of subversive masonry, having the joints of the masonry secured with a cement composed of pitch, resin and dry gypsum in equal parts. A door is fitted into it at one end,

which can be made air-tight by strips of cloth and clay lute. A window in each side enables the operator to judge how the impregnation goes on, by the colour of the air, and also gives light for making the arrangements within at the commencement of the process. As water lutes are incomparably superior to all others, where the pneumatic pressure is small, a large valve, or door, on this principle, is recommended to be made in the roof, and two tunnels, of considerable width, at the bottom of each side wall. The apartment would thus be ventilated, without the necessity of the workmen approaching the deleterious gas. A great number of wooden shelves, or rather trays, eight or ten feet long, two feet broad, and one inch deep, are provided to receive the sifted slacked lime, containing, generally, about two atoms of lime to three of water. These shelves are piled one over another in the chamber, to the height of five or six feet, cross-bars below each keeping them about an inch asunder, that the gas may have free room to circulate over the surface of the powder. The alembics for generating the chlorine, which are usually nearly spherical, are, in some cases, made entirely of lead; in others, of two hemispheres, joined together in the middle, the upper hemisphere being lead, the under one cast-iron. The first kind of alembic is enclosed, for two thirds from its bottom, in a leaden or iron case, the interval of two inches between the two being destined to receive steam from an adjoining boiler. Those which consist below of cast-iron have their bottom directly exposed to a very gentle fire. Round the outer edge of the iron hemisphere a groove is cast, into which the under edge of the leaden hemisphere fits, the joint being rendered air-tight by Roman or patent cement—a mixture of lime, clay and oxide of iron, separately calcined and reduced to a fine powder. It must be kept in close vessels, and mixed with the requisite water when used. In this leaden dome, there are four apertures, each secured by a water-lute. The first opening is about ten or twelve inches square, and is shut with a leaden valve, with incurved edges, that fit in the water channel, at the margin of the hole. It is destined for the admission of a workman to rectify any derangement in the apparatus of rotation, or to detach hard concretions of salt from the bottom. The second aperture is in the centre of the top. Here a tube of lead is fixed, which descends nearly to the bottom, and down through which the vertical axis passes, to whose lower end the cross-bars of iron or of wood, sheathed with lead, are attached; by whose revolution the materials receive the proper agitation for mixing the dense manganese with the sulphuric acid and salt. The motion is communicated either by the hand of a workman, applied from time to time to a winch at top, or it is given by connecting the axis with wheel-work, impelled by a stream of water or a steam-engine. The third opening admits the siphon-formed funnel, through which the sulphuric acid is introduced; and the fourth is the orifice of the education pipe. The proportion of the materials for generating the chlorine is as follows: 10 cwt. of salt are mixed with from 10 to 14 cwt. of manganese; to which mixture, after its introduction into the alembic, from 2 to 14 of sulphuric acid are added, in successive portions: that quantity of acid must, however, be previously diluted with water, till its specific gravity becomes about 1.65. The education pipes from all the alembics terminate in a leaden chest, or cylinder, with which they are connected by water-lutes, having a hydrostatic pressure of two or three inches. In this general *diversorium*, the chlorine is washed from adhering muriatic acid, by passing through a little water; and, from this reservoir, the gas is conducted off by one general pipe, and delivered into

the top of the chamber containing the lime, where, in consequence of its gravity, it diffuses itself equally over powder spread out upon the shelves. Four days are required for making good marketable bleaching-powder. The manufacturer generally expects from one ton of rock salt, employed as above, a ton and a half of good bleaching-powder. In using the chloride of lime for bleaching, the coloured cloth is first steeped in warm water, to clean it, and it is then repeatedly washed with a solution of caustic potash, so diluted that it cannot injure the texture of the cloth, and which solution is thrown upon it by a pump. The cloth is then washed and steeped in a very weak solution of the bleaching-powder; again washed, acted on by a boiling ley, as before, and again steeped in the solution; and these operations are performed alternately several times. The cloth is, lastly, immersed in very dilute sulphuric acid, which gives it a pure white colour; after which it is washed and dried. The chlorine is known to decompose water, whose hydrogen forms with it muriatic acid, which is always found in the solution (after the process) when liquid chlorine is used, and a muriate, when a chloride is employed. In a similar manner, it is believed to decompose the colouring matter, one of whose elements is always hydrogen; and, its composition being thus subverted, it disappears from the fabric with which it existed. Still more important is the use of the chloride of lime in counteracting contagion, and all noxious effluvia. MM. Orfila, Lescure, Gerdy, and Hennelle, having to examine the body of an individual who was supposed to have been poisoned, and who had been dead for nearly a month, found the smell so insupportable, that they were induced to try the application of the chloride of lime, as recommended by M. Labarraque. A solution of this substance was frequently sprinkled over the body, and produced the effect of destroying, after a few aspersions, every unpleasant odour. It was afterwards used in a still more desperate case, in clearing some offensive drains in Paris, with perfect success. It was also found to be the best and most durable means of disinfecting hospitals, &c. In such cases, the powder is so exposed to the infected region as to offer the greatest amount of surface, in order that the carbonic acid of the contagious atmosphere may expel the chlorine from the chloride of lime, which it does by combining with it to form carbonate of lime. A very convenient method of applying it to ordinary apartments, which we are desirous to free from unwholesome effluvia, is to diffuse about four ounces of the powder through five gallons of water, and sprinkle it over the floor by means of a water-pot.

Lime combines with the acids, neutralizing the acid properties. Its salts are, in general, decomposed by potash or soda, which precipitate the lime, but not by ammonia. Oxalic acid throws down lime from all the other acids; and, this compound being quite insoluble, oxalic acid forms the most delicate test of the presence of lime.

*Carbonate* of lime may be formed by adding carbonic acid to limewater, or by decomposing any of the soluble salts of lime by any of the alkaline carbonates. It is very sparingly soluble in water. Hence lime-water is an excellent test of the presence of carbonic acid. By an excess of carbonic acid, carbonate of lime is rendered soluble. When exposed to heat, it first loses what water it contains, and, if transparent and harl, becomes white, opaque, and friable. If the heat be augmented, the carbonic acid is expelled, and quicklime remains. The experiments of Sir J. Hall have proved that if carbonate of lime be heated under

strong pressure, so as to prevent the escape of the carbonic acid, it may be melted at a temperature even not higher than  $22^{\circ}$  of Wedgwood's scale. By this fusion, it acquires considerable hardness and closeness of texture, approaching, in these qualities, as well as in fracture and specific gravity, to the finer kinds of marble. The acids expel the carbonic acid with effervescence; and this property of effervescing strongly, on the contact of an acid, affords a discriminating character of this salt. Carbonate of lime abounds in nature.

*Nitrate* of lime may be formed by dissolving lime, or its carbonate, in dilute nitric acid. The solution, on evaporation, affords deliquescent, prismatic crystals, soluble in less than an equal weight of water, at the temperature of  $60^{\circ}$ , and in still less of boiling water. On being heated, it becomes phosphorescent, and retains this property when cold, forming *Baldwin's solar phosphorus*. It forms naturally in the plaster of old buildings.

*Sulphate* of lime is formed by adding lime to dilute sulphuric acid. It requires about 500 times its weight of water, at  $60^{\circ}$ , for its solution. At the temperature of  $212^{\circ}$ , it is more soluble, and this latter solution, on cooling, deposits minute crystals. Exposed to heat, it appears to effervesce, or boil, owing to the expulsion of its water; and, at the same time, becomes opaque, and falls into a white powder which, on being diffused in water, speedily consolidates from a species of irregular crystallization. Sulphate of lime is one of the most abundant minerals in nature.

*Phosphate* of lime may be formed by decomposing the solution of an alkaline phosphate by muriate of lime. It is a white, insoluble powder, which is imperfectly vitrified by a very intense heat. It exists in the mineral kingdom, under different forms, and constitutes eighty-six per cent. of the bones of animals.

*Muriate* of lime is obtained by dissolving carbonate of lime in muriatic acid. It is extremely soluble in water, the water taking up so much of it as to become of a thick consistence.

*Lime in Agriculture.* Quicklime, in its pure state, whether in powder, or dissolved in water, is injurious to plants. Grass is killed by watering it with lime-water. But lime, in its state of combination with carbonic acid, is a useful ingredient in soils. When lime, whether freshly burned or slacked, is mixed with any moist, fibrous, vegetable matter, there is a strong action between the lime and the vegetable matter, and they form a kind of compost together, of which a part is usually soluble in water. By this means, matter which was, before, comparatively inert, becomes nutritive; and, as charcoal and oxygen abound in all vegetable matters, the lime becomes converted into a carbonate. Mild lime, powdered limestone, marls, or chalks, have no action of this kind upon vegetable matter; by their action they prevent the too rapid decomposition of substances already dissolved; but they have no tendency to form soluble matter. From these circumstances, it is obvious, that the operation of quicklime and marl or chalk, depends upon principles altogether different. Quicklime, in the act of becoming mild, prepares soluble out of insoluble matter. It is upon this circumstance that the operation of lime, in the preparation of wheat crops, depends, and its efficacy in fertilizing peats, and in bringing into a state of cultivation all soils abounding in hard roots, or dry fibres or inert vegetable matter. The solution of the question, whether quicklime ought to be applied to a soil, depends upon the quantity of inert vegetable matter it contains. The solution of the question, whether marl, mild lime, or powdered limestone, ought to be applied, depends upon the quantity of calcareous matter already in the soil. All soils are improved

by mild lime, and, ultimately, by quicklime, who do not effervesce with acids; and some are more benefited by it than clays. When a soil, deficient in calcareous matter, contains much soluble, vegetable manure, the application of quicklime should also be avoided, as it either tends to decompose the soluble matters by uniting to their carbon and oxygen, so as to become mild lime; or it combines with the soluble matters, and forms compounds having an attraction for water than the pure vegetable substance. The case is the same with respect to animal manures; but the operation of the lime is different, in different cases, and depends upon the nature of the animal matter. Lime forms a kind of insoluble soap with oily matters, and then gradually decomposes them by separating from them carbon and carbon. It combines, likewise, with the mineral acids, and probably assists their decomposition, abstracting carbonaceous matter from them, combined with oxygen; and consequently, it must owe them less nutritive. It tends to diminish, however, the nutritive powers of albumen, from the same causes, and always destroys, to a certain extent, the efficacy of animal manures, either by combining with certain of their elements, or by giving to them other arrangements. Lime should never be applied to animal manures, unless they are too rich, or for the purpose of preventing noxious effluvia. It is dangerous when mixed with any common dung, tending to render the extractive matter insoluble. In some cases in which fermentation is useful to produce nutriment from vegetable substances, lime is very efficacious, as with tanners' bark. For the use of lime in building, see *Mortar*. Lime is much used by tanners, skinners, &c., in the preparation of leather; by soap-boilers, for dissolving the oils, facilitating its union with the alkaline matter; and sugar-bakers, for refining their sugar. It is also some medicinal use, being applied externally as a siccative and epulotic medicine.

*Native Salts of Lime, or Calcareous Minerals.* Of these, the first deserving of mention is the *nitrate of lime*, limestone, or *rhombohedral Limestone*. This species, in mineralogy, is one which, from its distribution, and the immense masses in which it frequently occurs, constitutes an important part of geology. Its mineralogical character may be expressed as follows: Fundamental or primary; an oblique rhomboid of  $105^{\circ} 5'$  and  $74^{\circ} 55'$ ; seven crystals (of which above 600 are, at present, known) are some variety of the rhomboid, the six-sided pyramid, or of a double six-sided pyramid, all of which are of the primitive rhomboid, by cleavage, with the perfect facility. No species in mineralogy is so interesting to the crystallographer as the nitrate. To it we owe our first correct ideas of the internal structure of crystals, and the best theory of crystallization which has ever been suggested. It is vitreous; prevalent colour white, also different shades of gray, red, green, and yellow, and dark brown and black colours, from foreign admixtures. It is grayish-white; transparent to translucent; its refraction very considerable and easily observed; brittle; hardness such as to admit of being cut with the knife; specific gravity 2.2. Besides occurring in distinct crystals, it exists in the form of a stucco, in botryoidal, and fruticose shapes, with smooth, uneven, drusy, rough or smooth; and composed of columnar, more or less distinct, straight, diverging, and of various sizes. Stalactitic and botryoidal varieties are often composed, a second time, of small lamellar particles, conformably to the surface of the imitative shape, the faces of composition being smooth and rough, or irregularly striated in a single direction. It also occurs massive; the texture

being either columnar, in which the individuals are straight, parallel, or diverging, and often of remarkable delicacy; or the composition is granular, the individuals being of various sizes, and even impalpable. The individuals, in these varieties, cohere more or less firmly. If the composition be impalpable, the fracture becomes splintery, uneven, flat, conchoidal, or even; on a large scale, it is sometimes scaly. The fracture is earthy in those varieties in which the individuals cohere but slightly. The breaking up of this species into sub-species and varieties, which was practised by the older writers on mineralogy, and which has left us numerous particular denominations, and no little confusion, requires notice in this place. These distinctions, it will be seen, depended chiefly upon the mode of composition, and upon admixtures and impurities with which the individuals have been affected during their formation. Of these, *limestone* represents the greater part of the pure varieties of the species. The simple varieties, and those compound ones in which the individuals are of considerable size, and easily cleavable, have been called *calcareous spar*; compound varieties of granular, still discernible individuals, are *granular limestone*; both comprehended under the head of *foliated limestone*. If the granular composition disappear, *compact limestone* is formed, under which denomination the *oolite*, or *roestone*, was comprehended. The roundish grains, however, of the latter, consist of columnar individuals, disposed like the radii of a sphere, and frequently showing distinct traces of cleavage. *Common fibrous limestone* is produced by columnar composition, in massive varieties; the *fibrous calcisinter*, by the same, but appearing in various imitative shapes. *Peastone*, or *pisolite*, consists of diverging columnar individuals, collected into curved lamellar ones, forming globular masses, which are again agglutinated by a calcareous cement. Each of the globules, generally, contains a fragment of some heterogeneous matter, as quartz, granite, &c. Compact limestone passes into *chalk*, when the individuals are more loosely connected with each other, so that the whole assumes an earthy appearance; and *rock milk*, or *agarie mineral*, is formed, if the mass contains so many interstices that it seems to possess but a small degree of specific gravity. *Calcareous tufa*, a recent deposit, formed on the surface of the earth, is often cleavable, and thus possesses all the properties of calcareous spar. *Slate spar* is produced by a lamellar composition, in massive varieties, and often exhibits a pearly lustre. *Scriestone*, *anthracolite*, *marl*, and *bituminous marble* are impure and mixed varieties, partly of calcareous spar, partly of compact limestone. The pure varieties of rhomboidal limestone consist of lime, 56, and carbonic acid, 43. Very often, the varieties contain variable proportions of oxide of iron, silica, magnesia, alumine, carbon, or bitumen. If pure, it is entirely soluble in nitric acid, during which a brisk effervescence takes place. In the common fire, it is infusible, but loses its carbonic acid, and becomes burned, or quicklime. Limestone rarely enters into the composition of rocks: in most cases, the more considerable masses of it form particular beds in other rocks, or constitute rocks themselves; the latter consist chiefly, though not exclusively, of compact limestone; the former of granular limestone. The simple varieties occur in drusy cavities, more frequently in veins than in beds, accompanied with the varieties of different species. Calcareous tufa and rock-milk, being of a sintery formation, occur upon the surface, and in fissures of limestone rocks. Stalactitic and pisiform varieties are produced by calcareous springs and other waters. The mixed, or impure varieties occur in particular strata,

between those of compound varieties of other species. It very often occurs in petrifications, imbedded in compact varieties of the same species. Rhomboidal limestone, as has already been remarked, is a species very widely diffused in nature; several of its varieties have a considerable share in the constitution of mountains, in many countries. This is particularly true in Switzerland, Italy, Carniola, Carinthia, Salzburg, Stiria, Austria and Bavaria, and in several parts of America. Of crystallized varieties, the most remarkable occur in Derbyshire and Cumberland, in the mining districts of Saxony and Bohemia, in the Hartz, in Carinthia, Stiria, Hungary and France, and, in the United States, at Lockport in New York, forming geodes in compact limestone. Iceland is the locality of the purest and most transparent varieties, from whence come the best pieces of the doubly-refracting spar. The crystallized sandstone of Fontainebleau, in France, is a variety of rhomboidal limestone, mechanically mixed with sand. Slate-spar occurs in Saxony, Norway and Cornwall. Pisolite is found in Carniola, and at Carlsbad in Bohemia. Most of the varieties are so common as to render the mention of their localities unnecessary. Several varieties of the present species are usefully employed for various purposes, partly depending upon their mechanical, partly upon their chemical composition. Those used in sculpture and in ornamental architecture, are called *marble*; the more common or coarse varieties are used for the common purpose of building; a peculiar variety of very fine-grained compact limestone is used for plates in lithography. The best sort is found near Pappenheim and Sohlenhofen, in Bavaria. Quicklime mixed with sand and water forms mortar. Carbonic acid, for chemical purposes, is often obtained from chalk or marble powder. It is also a valuable addition in several processes of melting ores, and in producing certain kinds of glass. There is another species, in mineralogy, called *Arragonite*, which was formerly confounded with that just described. In composition, it is scarcely distinguished from rhomboidal limestone, the most accurate analysis having been unable to make known more than from 5 to 4.1 of carbonate of strontites in its composition, besides carbonate of lime. Its crystallization, and other characters, however, sufficiently characterize it as distinct from limestone. It occurs in crystals, which, at first sight, appear to be regular six-sided prisms; but a close inspection will discover a longitudinal crevice down each lateral face, and somewhat similar appearances converging in the centre of the terminal planes. It also occurs in prismatic crystals, of four or six sides, terminated by planes; the prisms often being so short as to impart to the crystal the general form of an octahedron; these are rarely separate, but mostly cross each other at particular angles. Its crystals yield to mechanical division, parallel to the lateral planes of a right rhombic prism of  $116^{\circ} 5'$  and  $63^{\circ} 55'$ , by measurement taken with the reflective goniometer, on cleavage planes. Lustre vitreous, inclining to resinous, upon faces of fracture; colour white, sometimes passing into gray, yellow, or mountain green; transparent or translucent; brittle; hardness such as to scratch calcareous spar; specific gravity, 2.93. It is very liable to occur in globular, reniform, and coralloidal shapes, and massive, with a columnar composition. Imbedded crystals, generally twins, or consisting of a greater number of individuals, are found in compound varieties of gypsum, mixed and coloured with oxide of iron, accompanied with crystals of ferruginous quartz. Other varieties occur in the cavities of basalt and other trap rocks, in lavas, also in irregular beds and veins. It is found in beds of iron ores, in those coralloidal

varieties which have been called *floc-ferri*; also massive and crystallized. The first, though they occur in cavities and fissures, are not products of a stalactitic formation. The most beautiful crystals, well defined and transparent, occur near Bilin, in Bohemia, in a vein traversing basalt, and filled with a massive variety of the same species, consisting of large columnar particles of composition. The varieties imbedded in gypsum have been found in the kingdom of Arragon, in Spain, from whence the name *Arragonite* has been derived. Its chief localities are the iron mines of Stiria, Carinthia and Hungary, and the metallic veins of the Pyrenees and Great Britain.

*Sulphate of lime, or gypsum*, is a mineral little less extensively diffused than limestone, forming immense beds and veins, in numerous countries. It presents us with a very considerable diversity of crystals, which have, for their primary form, a right-oblique-angled prism, of which the bases are oblique-angled parallelograms of  $113^{\circ} 8'$  and  $65^{\circ} 52'$ . The crystals are either prismatic or lens-shaped, in their general aspect. Lustre vitreous, inclining to pearly; colour white, sometimes inclining and passing into small blue, flesh-red, ochre-yellow, honey-yellow, and several shades of gray. Impure varieties assume dark gray, brick-red, and brownish-red tinges. Transparent or translucent; sectile; specific gravity, 2.31. It occurs massive, in globular masses, in which the individuals are discernible; also granular, passing into impalpable. Those varieties of sulphate of lime which are pure, transparent, and perfectly formed, were formerly called *selenite*, while the more massive and impure varieties were denominated *gypsum*. The latter was again divided into several sub-species, comprehending, almost exclusively, compound varieties, which were easily distinguishable from each other, as their division depended upon the size of the grain, or composition in general. Thus *foliated gypsum* consists of discernible granular particles; *compact gypsum*, of impalpable particles of composition; *scaly foliated gypsum* consists of minute scaly particles; *earthy gypsum*, of a mealy powder; very thin columnar composition produces *fibrous gypsum*. Before the blowpipe, gypsum exfoliates and melts, though with difficulty, into a white enamel, which, after a short time, falls to powder. In a lower degree of heat, it loses its water, and becomes friable, so as to be easily reduced to an impalpable powder. If mixed with water, this powder becomes warm, and soon hardens into a solid mass. It is composed of lime, 33.0, sulphuric acid, 44.8, and water, 21.0. The massive varieties of this species occur in beds, of a considerable thickness, in secondary districts, in connexion with compact limestone, different kinds of sandstone and clay, in alternating layers, in the latter of which the gypsum sometimes exists in imbedded masses, or crystalline groups. It is not rare to find deposits of rock-salt in its vicinity; and brine springs very often issue from the contiguous rocks. Of the organic remains found in gypsum, those of extinct species of terrestrial quadrupeds, in the Montmartre, near Paris, are the most remarkable. It occurs in a great many countries, particularly in Germany, Switzerland, Austria, Poland, Britain, France and Spain; in North America, in the United States, at Niagara falls, Lockport, and particularly in the vicinity of Cayuga lake; and in New Brunswick and Nova Scotia. Gypsum is variously employed in manufacturing artificial marble, stucco-work, mortar, &c.; also for making casts of statues, medals, &c. It is added to the mass of certain kinds of porcelain and glass. In sculpture, it is used under the name of *ambaster*. But next to its use in the formation of

cements, is the use which is made of it in agriculture. It appears to have been first used as a manure in Germany, and afterwards in France. It was formerly calcined, but is now ground in situ, after the manner of grain. It is particularly adapted to sandy soils and grass lands. Another species of the same composition with the gypsum, except the water, is called *anhydrite* (q. v.). It is of comparatively rare occurrence.

*Phosphate of lime, or apatite*, is found crystallized in six-sided prisms, terminated by one or more planes, or the prism is terminated by a six-sided pyramid, and the lateral edges are sometimes replaced by numerous planes. It yields with difficulty to cleavage, parallel to the side of a regular six-sided prism, which is therefore considered as its primary form. Lustre vitreous, inclining to resinous; colour white, passing into blue, green, yellow, red, and brown; transparent or translucent; brittle; hardness above that of fluor; specific gravity, 3.22. It also occurs massive. When in fine powder, it is easily dissolved in nitric acid, and without effervescence. Some varieties are phosphorescent upon ignited charcoal, and before the blowpipe; others even when rubbed with hard bodies. It does not melt alone, before the blowpipe. It is composed of lime, 56.4, and phosphoric acid, 45.0. It usually occurs in beds and veins of iron and tin ores. Its principal localities are Saxony, Bohemia, Salzburg and Cato de Gata, in Spain; from which latter place very beautifully crystallized specimens are obtained, and which have received, from their colour, the name of *apategus stone*. It is also found at St Gothard, and at Devonshire and Cornwall.

*Fluate of lime.* See *Fluor*.

*Tungstate of lime, or tungsten*, occurs massive and crystallized in the form of an octahedron with a square base. Lustre vitreous, inclining to adamantine; colour generally white, inclining to yellowish-gray; translucent or transparent; brittle; hardness that of fluor; specific gravity, 6; infusible before the blowpipe. It consists of lime, 19.40, oxide of tungsten, 80.42. It is found in Bohemia, Saxony and Cornwall.

*Borate of lime.* See *Boracæ Acid*.

*Arseniate of lime, or pharmacolite*, is a very rare species in mineralogy, found in small quantity at Andreasburg, in the Harz, and at one or two other places in Europe. It occurs in minute fibrous, or acicular crystals, which are commonly aggregated into botryoidal or globular masses. Its colour is white, or grayish-white, though often tinged of a violet-red, by arseniate of cobalt, which accompanies it. Specific gravity, 2.6. It consists of lime, 28, arsenic acid, 50.54, and water, 24.46.

LIMERICK; one of the six counties included within the province of Munster, Ireland. It is bounded on the north by the river Shannon; on the south by the county of Cork; on the east by Tipperary, and on the west by Kerry. It is 51 miles from north to south, and 32 from east to west. The country rises to a considerable extent wheat, barley, oats, rape, and hemp.

LIMERICK, the capital of the above county is situated on the Shannon, 119 miles S.W. of Dublin and 63 N.W. of Cork. The principal public buildings are the custom-house, the cathedral, and the bishop's palace. The cathedral is of great antiquity. There are several charitable establishments, also a good public library, and a theatre. It contains four Protestant churches, and eight chapels for the Roman Catholics. There is also an extensive hospital for twenty-two companies of foot and four troops of horse. Limerick carries on manufactures of linen, woollen and paper. It was taken by the English in 1702. In 1661, it was taken by Ireton. In 1690 it was

unsuccessfully besieged by king William in person. In 1691, it surrendered to general Ginkle, afterwards earl of Athlone. Population, from 50,000 to 60,000, in which are 5000 Protestants.

LIMIT, in a restrained sense, is used by mathematicians for a determinate quantity, to which a variable one continually approaches; in which sense, the circle may be said to be the *limit* of its circumscribed and inscribed polygons. In algebra, the term *limit* is applied to two quantities, one of which is greater, and the other less, than another quantity; and, in this sense, it is used in speaking of the limits of equations, whereby their solution is much facilitated.

LIMNING (from *entluminer*, French, to adorn books with paintings). As these paintings or illuminations were always executed in water-colours, *limning* properly designates that species of art which is now known by the name of *miniature painting*, though it is sometimes used to signify the art of painting generally, and particularly portrait painting.

LIMOGES (*Augustoritum*, or *Lemovicum*); a city of France, capital of the department of the Haute-Vienne, and formerly of the province of Limousin; lat. 45° 50' N.; lon. 1° 16' E.; episcopal see; 25,612 inhabitants. It is an ancient place, and contains some Gaulish and Roman remains. The *hôtel de ville*, cathedral, and episcopal palace, are the principal public buildings. It is also the seat of several literary establishments, and has woollen, linen and cotton manufactures, with paper works, tanneries and iron forges. Several fairs are held here. Birth-place of the chancellor D'Aguesseau.

LIMONADE; a place and plantation in Hayti, very rich in sugar. It was elevated to a lordship by king Christophe, and bestowed upon his minister for foreign affairs, whom he made count de Limonade. With the death of Christophe, the count de Limonade returned to obscurity. Though ridiculed by whites, on account of his title, he showed talents in the conduct of his office. It is not true that Christophe killed him in 1817, as has been said.

LIMONADIÈRE; a very essential personage in a French *café*. See *Coffee-Houses*, under *Coffee*.

LIMOUSIN, or LIMOSIN; an ancient province in the centre of France. Limoges was the capital. It forms at present the chief part of the departments of Haute-Vienne and of Corrèze. See *Department*.

LINCOLN, (the *Lindum Colonia* of the Romans), an ancient and once distinguished city of England, situated 132 miles N. W. from London. It is the capital of the county to which it gives name, but under a separate jurisdiction, as forming with the surrounding district a distinct county, between the parts of Lindsey and Kesteven. It occupies the summit and side of a hill, at the base of which flows the river Witham, in three channels, crossed by several bridges; and from the level nature of the surrounding country, its buildings, and especially the cathedral church, are advantageously seen in several directions at a considerable distance. Lincoln was at one time a place of great ecclesiastical importance; but of its fifty churches, eleven only, besides the cathedral, remain. The cathedral, a magnificent structure, is still in good preservation; but of the castle, built by William I., only a few ruins remain. Lincoln has an extensive trade in corn and wool. Population in 1831, 11,892.

LINCOLNSHIRE, a county of England, which extends along the German ocean from the Humber, its northern boundary, to the arm of the sea, called the Wash, that runs up between the coasts of Lincoln and Norfolk. It is bounded on the south by the counties of Cambridge and Northampton, and on the west by those of Rutland, Leicester, Nottingham,

and York. It extends seventy-seven miles from north to south, and about forty-eight from east to west, being with the exception of Yorkshire, the largest county in England. It is divided into three districts—Lindsey, Kesteven, and Holland. The district of Lindsey is the most extensive, comprehending the whole of the county, north of the Fossdike and the river Witham. Towards the north-east is a large tract of heathy land, called the Wolds, extending from Barton-on-the-Humber to Spilsby, consisting principally of sandy loam and flint; and on the western side the substratum is a sandy rock. Throughout this tract are bred large flocks of sheep, of a kind distinguished for their long thick wool, much used in the manufacture of worsted stuffs and coarse woollens. Here also were formerly kept a great number of rabbits, their skins and fur being valuable articles of commerce; but the rabbit-warrens in many places have been destroyed of late years, and the ground broken up for tillage. The north-western part of Lindsey includes the river island of Axholme, formed by branches of the Trent, the Dun, and the Idle, a low fertile tract, in which flax is much cultivated, as also hemp, rape, and turnip-seed. The district of Kesteven contains the western part of the county, from near the centre to the southern extremity. Its soil exhibits considerable diversity; but though some tracts of heath occur, it is on the whole a fruitful country; the heaths, particularly those of Ancaster and Lincoln, having been enclosed and cultivated. The principal river of Kesteven is the Witham, which rises near Grantham, and flowing north-east to Lincoln, makes a semicircular sweep, and taking its course south-eastward, falls into the German Ocean, below Boston. It is in the former part of its channel a shallow stream, but becomes navigable at Lincoln, where it communicates with the Fossdike. The jack, or pike, is a fish said to be very abundant in this river. The fens, for which Lincolnshire is noted, are partly in the district of Kesteven, but by far the larger portion of them belongs to the district of Holland, so called from its characteristic feature, being hollow or low land, like the province of the Dutch Netherlands bearing a similar appellation. This part of the county is smaller than either of the two preceding, occupying the south-eastern quarter, bordered on one side by the shallow inlet of the sea, called the Wash. Holland consists of two divisions, upper and lower, both composed of fens and marshes, many of which have been reclaimed, and converted to the purposes of agriculture by the construction of numerous drains and canals, together with raised causeys. The lower, or southern division, is the most watery, and is only protected from the devastating effects of inundations by immense embankments on the sea-coasts and the borders of the rivers. Where the operations of draining have been carried into effect, the air though damp, is not unwholesome, and hence intermittent fevers, rheumatism, and other diseases of marshy countries, have become comparatively unusual. Among the undrained fens are bred vast flocks of geese, which form a considerable source of commerce, on account of their quills and feathers, and also as an article of provision. The principal decoys in England for wild ducks, teal, widgeon, and other water-fowl, are in this district; and hence the London markets are chiefly supplied. Wild geese, grebes, godwits, wimbrels, coots, and a numerous variety of other aquatic birds, breed here abundantly, and obtain a plentiful supply of food from the fishy pools and streams. Stares or starlings resort hither during the winter to roost in their reeds, and in such vast multitudes as to crush the stalks by their weight. Near Spalding is said to be the greatest heronry in

England, where the herons build their nests like rooks, in clusters, on the tops of lofty trees. The avocet or yelper, distinguished by its bill, which curves upwards, is found in considerable numbers in the neighbourhood of the Fossdike; as likewise are those delicacies for the table, knots and dottrels.

Among the agricultural products of Lincolnshire in general, are grain of all sorts in the higher grounds; and in the lower oats, hemp, flax, woad, &c. But its distinguishing character is that of a grazing county, and its pastures are noted for rearing different kinds of stock of the greatest size and weight. Lincolnshire oxen are proverbially remarkable for their immense bulk; and the horses bred here have long been held in high repute, both for the saddle and for harness, while those from the southern part of the county are especially valuable as draught horses. The mineral productions of Lincolnshire are of but little importance in commerce, the only articles deserving of notice being a kind of variegated marble, the ore called the sulphuret of iron, and the subphosphate of the same metal. This is not a manufacturing county, but in some towns canvass and sail-cloth are made in considerable quantities.

The boroughs of Lincolnshire, beside the city of Lincoln, are Boston, Grantham, Grimsby, and Stamford; and the market-towns, Alford, Barton-upon-Humber, Bourne, Burgh, Caistor, Corby, Crowland, Crowle, Donnington, Epworth, Falkingham, Gainsborough, Glandford Bridge, Holbeach, Horncastle, Kirtton, Louth, Market Deeping, Market Rasen, Saltfleet, Sleaford, Spalding, Spilsby, New Bolingbroke, Long Sutton, Swineshead, Tattershall, Wainfleet, and Wragby. Population in 1831, 317,244.

LINDSAY, or LYNDSEY, SIR DAVID, an ancient Scottish poet, descended from a noble family, was born about the year 1490. He entered the university of St Andrews in 1505, and, in 1509, became page of honour to James V., then an infant. In 1528, he produced his *Dreme*, and, in the following year, presented his *Complaynt* to the king. In 1530, he was inaugurated Lyon king-at-arms, and knighted, and, in 1531, sent on a mission to Charles V., on his return from which he married. He soon after occupied himself on a drama, of a singular kind, entitled a *Satyre of the Three Estatis*, which was followed, in 1536, by his *Answer to the King's Flying*, and his *Complaynt of Bascha*. On the death of Magdalen of France, two months after her marriage with James V., Lindsay's muse produced his *Deploration of the Death of Quene Magdalene*. During the succeeding regency, he espoused the cause of the reformers, and, in 1548, was sent, in his capacity of Lyon herald, on a mission to Christiern, king of Denmark. On his return, he published the most pleasing of all his poems, entitled the *History and Testament of Squire Meldrum*. His last and greatest work, the *Monarchie*, was finished in 1553. The date of his death is unknown; but the latest authority seems inclined to place it in 1557. Lindsay entered with great zeal into religious disputes, and his satires powerfully assisted to expose the vices of the clergy. As a poet, he is inferior to Dunbar and Gavin Douglas. His *Dreme* is deemed his most poetical composition. An accurate edition of the works of Lindsay was published by Mr George Chalmers, in 1806.

LINDSEY, THEOPHILUS, a celebrated divine of the Unitarian persuasion, was born at Middlewich, in Cheshire, June 20, 1723. His father was an eminent salt proprietor; and Theophilus, the second of his three children, took that name from his godfather Theophilus, earl of Huntingdon. He received his grammar education at Middlewich and Leeds, and, at the age of eighteen, was admitted a scholar at St

John's college, Cambridge. Having taken orders, by the recommendation of the earl of Huntingdon, he was appointed domestic chaplain to the duke of Somerset, and, in 1754, accompanied earl Percy to the continent. On his return, he married the daughter of archdeacon Blackburne, and was permitted to a living in Dorsetshire, which he exchanged, in 1764, for the vicarage of Catterick, in Yorkshire. In 1771, he zealously co-operated with archdeacon Blackburne, doctor John Jebb, Mr Wynn, and others, to obtain relief in matters of subscription to the thirty-nine articles. Having long entertained a doubt of the doctrine of the Trinity, in 1772, he honourably resigned his livings, and went to London, where, in April, 1774, he performed divine service in a room in Essex-street, Strand, which was conducted according to the plan of a liturgy, altered from that of the establishment by the celebrated doctor Samuel Clarke. About the same time, he published an *Apology*, of which several editions were called for in a few years. This was followed by a larger volume, entitled a *Sequel to the Apology*, in which he replied to the various answers given to his first work. In 1778, he was enabled, by the assistance of friends, to build a regular chapel in Essex-street, the service of which he conducted, in conjunction with doctor Disney, until 1793, when he resigned the post, but continued as active as ever with the pen. In 1802, he published his last work, entitled *Considerations of the Divine Government*. He died Nov. 3, 1803, at his eightieth year. Besides the works already mentioned, he wrote on the *Preface to St John's Gospel*, on *Praying to Christ*, an *Historical View of the State of the Unitarian Doctrine and Worship from the Reformation*, and several other pieces. Ten volumes of his sermons have also been published since his death.

LINE, MATHEMATICAL, is extension in length without breadth and thickness; it is either straight or curved. In navigation, the equator is called *the line*; hence the expression "to pass the line." In decimal measures of length, it is the tenth; in the decimal measures of length, it is the twelfth part of an inch. In the art of war, a series of numbers of ships, drawn up in order of battle, are called a *line*; hence the phrase "ships of the line." In grammar and jurisprudence, it signifies a series of persons, in the order of their descent from a certain ancestor.

LINE, TROOPS OF THE, are contradistinguished from the guards and light troops.

LINE, VESSELS OF THE. See *Navy*, and *Ship*.

LINEN; a cloth of very extensive use, made of flax, and differing from cloths made of hemp, &c. in fineness. In common linen, the warp and weft cross each other at right angles; if figures are woven in, it is called *damask*. The species of goods which come under the denomination of linen, are table-cloth, plain and damasked, cambric, lawn, shirting, sheeting, towels, Silesias, Osnaburghs, &c. The chief countries in which linens are manufactured are Russia, Germany, Switzerland, Flanders, Holland, Scotland and Ireland. Of these, Russia principally manufactures sheeting and sail-cloth; Germany, shirting, sheeting and bagging; Switzerland, both fine and coarse goods; Flanders, the finer articles, especially cambric and lawn; Holland, sheeting of the best description; Scotland and Ireland, shirting, damask table-cloth, and towelling, of superior quality. Immense quantities of linen are annually exported from Ireland to England, and several parts of Europe, and North and South America, the West Indies, and Africa; in several parts of Germany, Switzerland, Flanders, and France, linens are frequently embellished with painting; and in England, the produce of the Irish linen manufacture is beautifully printed in the manner of

**cotton.** The beauty of linen consists in the evenness of the thread, its fineness, and density. The last of these qualities is sometimes produced by subjecting it to rollers; hence linen with a round thread is preferred to that with a flat thread. The warp or woof is not unfrequently made of cotton yarn, which renders the cloth less durable, and named union cloth.—In an historical view, linen is interesting, as forming the dress of the Egyptian priests, who wore it at all their religious ceremonies; hence they are styled by Ovid and Juvenal, "linen-wearing." (See also *Gen. xvi. 8*, and *Spencer (on the Laws and Rituals of the Jews)*. From Egypt, linen passed to the Romans, but not till the time of the emperors. The Roman priests also began to wear linen garments at that time. Linen was also used as a material for writing, though the expression *libri lintei, cartaginei*, was also applied to cotton and silk, as well as linen. The Sibylline books and the mummy bandages, covered with hieroglyphics, are proofs of this use of linen. In the middle ages, linen and woollen cloth formed the only materials for dress; and fine linen was held in very high estimation; even the writer of the *Nibelungen-lied* mentions it. Germany and Brabant then carried linen manufactures to the greatest perfection. Linen was yet necessary for the manufacturing of good paper. Cotton lino, of late years, taken the place of linen for many purposes, on account of its greater cheapness. See *Cotton*, and *Paper*.

The horn manufacture has been prosecuted in England for a very long period; but though its progress has been considerable, particularly of late years, it has not been so great as might have been anticipated.

In 1804, both houses of parliament addressed his Majesty (Wm. III.), representing that the progress of the woollen manufacture of Ireland was such as to prejudice that of this country; and that it would be for the public advantage, were the former discouraged, and the linen manufacture established in its stead; his majesty granted their request. It is but justice, however, to the parliament and government of England, to state that they have never discovered any backwardness to promote the linen trade of Ireland; which, from the reign of Wm. III. downwards, has been the object of regulation and encouragement. Yet it may be doubted whether the regulations have been always the most judicious that might have been devised, and whether Ireland has really gained any thing by the forced extension of the manufacture. Besides premiums and encouragements of various kinds, bounties were granted on the exportation of linen for a very long period down to 1830. In 1829, for example, notwithstanding it had then been very much reduced, the bounty amounted to about £100,000, or to nearly one seventh part of the entire real or declared value of the linen exported that year. These bounties generally had a very bad effect, toward the latter period of their existence, on linens produced for exportation. The pieces deteriorated in quality, in consequence of the manufacturer studying rather to secure the bounty than to produce a superior article. The result of such a mode of procedure was entirely to begethred, so long as sales could be effected and the bounty obtained. No sooner was the bounty withdrawn, than the manufacturer perceived that the superiority of his cloth only could enable him successfully to compete in a foreign market. Hence, from that period the utmost attention has been bestowed to the strength of material and durability of texture in this staple branch of our manufacture. Indeed, after all, the business never began to do any real good, or to take firm root, till the manufacture ceased to be a domestic one, and was carried on principally in mills, and by the aid of machinery—a change which

the old forcing system tended to counteract. The only real and effectual legislative encouragement the manufacture has ever met with, has been the reduction of the duties on flax and hemp, and the relinquishing of the absurd attempts to force their growth at home.

*Table of the Quantity and Value of the L. items reported from Ireland, from 1870 to 1879, both inclusive.*

Years.	To Great Britain.	To Foreign Parts.	Amount of Brevity paid in Ireland, on Loans exported to Foreign parts.
	Years.	Years.	£. s. d.
1760	31 9 10 30	3 30 29	10 548 1 6
1761	66 11 27 10	3 12 35	11 965 9 11
1762	4 11 10 30	6 11 10 30	1 215 19 11
1763	62 1 10 30	3 3 3 30	17 12 1 6
1764	65 10 1 10	1 1 1 10 30	1 65 1 10
1765	66 10 1 10	2 6 6 7	17 116 13 10

1769	three years, the latter on Account	1 1 1 10	9 306 7 1 6
1770	trade having been now closed	2 6 6 7	6 6 6 1 11
	on all a rising of trade.		

Of these exports, more than 12-13ths have been to Great Britain. The total average export, during the three years ending with 1825, was 51,947,413 yards, of which 49,031,073 went to England; the exports to all other parts being only 2,916,340. Since 1825, the trade between Ireland and Great Britain has been placed on the footing of a coasting trade, so that linens are exported and imported without any specific duty at the custom-house.

*Scotch Linen Manufacture.*—In 1787, a board of trustees was established in Scotland for the superintendence and improvement of the linen manufacture. It is not easy to suppose that the institution of this board could of itself have been of any material service; but considerable bounties and premiums being at the same time given on the production and exportation of linen, the manufacture went on increasing. Still it did not increase so fast as cotton, so that it is very doubtful whether the influence of the bounty has been so great as it would at first sight appear to have been. The regulations as to the manufacture, after having been long objected to by those concerned, were abolished in 1822; and the bounties have now ceased.

*Account of the Quantity of the Foreign Linens retained for Home Consumption in Great Britain, in the Year ended 5th of January, 1831.*

Species of Linum.		Quantity realized for linum (unwashed) in Great B. town.

Dundee is the grand seat of the Scotch linen manufacture; and its progress there during the last few years has been extraordinary. The manufacture appears to have been introduced into Dundee sometime about the beginning of last century. In 1745, only seventy-four tons of flax were imported, without any hemp; the shipments of linen cloth during the same year being estimated at about 1,000,000 yards, no mention being made either of sail-cloth or bagging. In 1791, the imports of flax amounted to 2,444 tons, and those of hemp to 299 tons; the exports that year being 7,842,000 yards linen, 280,000 yards sail-cloth, and 65,000 do. bagging. From this period the trade began to extend itself gradually, though not rapidly. About 1815, in consequence, partly and principally of the improvement of machinery, and its extensive introduction into the manufacture, and partly of the

greater regularity with which supplies of the raw material were obtained from the Northern powers, the trade began rapidly to increase, and the imports of flax have increased from about 3,000 tons in 1814, to 15,000 tons in 1830. The exports of manufactured goods have increased in a corresponding proportion. In the year ending the 31st of May, 1833, the imports of flax amounted to 18,777 tons, besides 3,380 tons of hemp. The shipments of linen, sail-cloth, &c., have increased in a corresponding ratio; and were valued, in the year now mentioned, at about £1,600,000, as much as is exported from all Ireland, and has increased at Dundee more rapidly than the cotton manufacture has increased at Manchester.

The entire produce of the manufacture in the United Kingdom may be valued at £7,500,000; and the total number of people employed about 172,000.

*An Account of the Quantity of Flax and Tow Imported into and Exported from the United Kingdom, the Quantities entered for Home Consumption, and the Net Produce thereof, in each Year, commencing 5th January, from 1820 to 1831, both inclusive.*

Years.	Imports.	Exports.	Consumption.	Net Residue.

**Manufacture.**—The first process that the flax has to undergo, is that of heckling. This operation consists in drawing a handful of the flax, lengthways, over a sort of comb formed of iron or steel teeth, so as to separate the coarse part, or the tow, from the fine fibres, properly called flax. These combs or heckles are of various degrees of fineness, the flax being passed through them in succession, commencing with the coarsest. The heckling is performed either by the hand, or by machinery, according to the particular kind of yarn that is intended to be spun; but, it is probable, that ere long, such improvements will be made in the heckling machine, (which is extremely simple in construction), that heckling by the hand will be entirely done away.

The flax, thus prepared, is taken to the spreading machine, represented in plate 48. figs. 1 and 2. Fig. 1 being a side, and fig. 2, an end view. The process is somewhat similar to the spreading in the cotton manufacture, a description of which has been given under the article *Cotton manufacture*. The object of spreading the flax is, to form a sliver of uniform thickness, or such, that a foot in length taken at any one place will be equal to a foot in length, taken at any other place, or as nearly so as possible. A handful of the heckled flax is taken up by the attendant, and laid upon an endless cloth, A A fig. 1, the upper surface of which is kept continually moving towards the body of the machine, by means of the two rollers B B. The attendant, by practice, knows the proper quantity to spread on the cloth in a given time, in order to produce the sliver of the requisite girth. In cotton-spinning, the attendant is not intrusted with this, as the cotton is all weighed into proper parcels, before it comes to the spreading frame. The endless cloth, by moving forward, carries the spread flax to the rollers C C, which are called retaining rollers. The undermost of these rollers is put in motion by communication with the wheel-work, the spindle on which it revolves, being furnished with a pinion on the end, and the upper one receives motion, by being pressed upon the lower

one, by means of a lever, which is seen rising above it, the pressure being regulated by a screw at the top. So far the flax spreading resembles the cotton spreading, but at this point a new feature is exhibited in the process for flax. The flax having passed through the retaining rollers, is led over a series of heckles, seen at D. This heckling department is, perhaps, the most curious part of the machine. It is an endless chain of heckles moving in the same direction as the endless cloth. The chain is formed of brass links, fashioned so as to be caught by projections, or flattened teeth; in the two wipers which are seen at E, the one further from the retaining rollers being put in motion by the wheel-work, as may be seen by inspecting fig. 1. The other is a sort of friction roller, and is put in motion by the chain passing over it. Each link of the chain carries a kind of fork, closed at the top, the space between the prongs being designed as a guide to the end of a rod, stretching across the machine, so that the rod will rise or fall. The ends of these rods pass through these fork-formed guides, and pass into a groove cut in a side piece of the machine. In the centre of the ends of the cross rods, which are called the *gill bars*, are seen in the side view. The groove is somewhat irregular in form, or, to speak more properly, is not like any simple geometrical figure. In the under part, it passes in a direct line between the wheels, and then round their circumference, after which it takes a sudden rise up to the points *g g*, a considerable height above, the wheels keeping the elevation from *g g*. By this arrangement, it will be seen, that as the endless chain moves along the gill bars or cross-rods will move with it, being carried along by the forked guides on the links, and at the same time, these gill bars will rise up or down according to the direction of the groove. Thus when the gill bars are under the wheels as they will be very near to the links of the chain, but when they turn round the wheel as *ascend* to the endless cloth, they will begin to rise, and being carried along, at the altitude *g g*, will fall, when they come near to the other wheel. Now, as these gill bars carry the gills, or heckle teeth, they will of course have a similar motion. Hence, the gills or heckle teeth, do not rise above the forked guides until they arrive at that part where they should come into contact with the flax. The flax having passed through the chain of heckles, is received by the drawing rollers E E, the lowermost of which is driven by the wheel-work of the machine, and the upper one put in motion by being pressed upon it. From the drawing rollers, the flax is led through the intermediate rollers F F, and from these, it passes through the delivering rollers G G, and thence into a cut (not shown in the plate, to save room), in the form of a sliver, or flat band of flax fibres. The machine is put in motion by a band led from a shaft connected with the first mover, the band being passed round the pulleys at H H, one of which is fast, and the other loose, so that by shifting the belt, the machine may be put either in or out of gear. These powers are shown in fig. 2, which is a front elevation of the spreading machine.

The can containing the sliver is now taken from the spreading machine, and carried to the back of the preparing or drawing frame. This frame is represented in plate 49. figs. 3 and 4, fig. 3 being an end elevation, and fig. 4 a ground plan. The principal difference between this machine, and the cotton-drawing frame, consists in the introduction of heckles, fashioned in the same way as those in the flax-spreading frame. The chain, in this case, being horizontally, instead of obliquely, as may be seen at C, fig. 3. The can H, from the spreading frame, is

placed at the back of the machine, and the sliver A is led from it through the retaining rollers B B B, passing under the first, over the second, and under the third, from which last it is led over the gills at C. The sliver then passes through between the drawing rollers D D, which move quicker than the retaining rollers B B B, and the sliver receives a second drawing, the first having been given in the spreading machine. From these drawing rollers the sliver is passed through the delivering rollers, commonly called the delivering ball, and is seen at F, falling into the can G. The increase of the length of the sliver, or the quantity of draught, will, of course, depend on the comparative speed of the drawing and retaining rollers. On inspecting the plan, fig. 4, it will be seen that the drawing frame is put in motion by means of a belt and pulleys.

The drawn sliver is next taken to the roving frame. The use of this roving machine is to give the rove another drawing, also a slight twist, and likewise to wind it upon a bobbin. The machine is somewhat analogous to the fly frame used in the cotton manufacture, with the exception of the gills, or endless heckle, introduced in this machine as in the two former. The flax roving frame is represented, in end view, by fig. 3, and in front elevation by fig. 4, plate 48. The can G is taken from the drawing frame and placed at the back of the roving frame, as seen in the end view. The sliver A is led out of it and passed through the guide a, under the first retaining roller B, over the second B, and under the third B; from whence it is led through the gills in the endless heckle C, then through the drawing rollers D D, which, as they move quicker than the retaining rollers, give another draught to the sliver. From the drawing rollers, which act also as delivering rollers, the flax passes into the flyer f through the top of the spindle E. The spindle and flyer are kept revolving by means of hands passed round the pulleys g, which hands are led over the revolving cylinder A. The revolution of the spindle and flyer causes the rove, which is now called rove, to be wound upon the bobbin F, which rests upon the cross rail K. The bobbin rail is moved up and down alternately by means of the lever H, which is raised and depressed by its connection with the heart wheel G, as may be seen in fig. 3. The train of wheel work is so obvious in the engraving that description is unnecessary. It is clear that in this, as in the cotton-roving frame, the rove, by passing through the top of the spindle, receives a slight twist ere it is wound upon the bobbin.

All the processes we have described are merely preparatory for the spinning of yarn, which last remains now to be considered. Fig. 1, plate 49, is a front elevation, and fig. 2 an end view of the flax spinning frame, which acts on similar principles with the cotton Throstle. A is the bobbin rail on the top of the machine; the rail is furnished with pins projecting from the side, on which the bobbins from the roving frame are placed, lying in a horizontal position, the ends being seen in the front elevation at F. The sliver A is led from three bobbins through between the retaining rollers C C, from whence it is passed over grooves formed in the rod D, and subsequently through between the delivering rollers E E, which move at a much quicker rate than the retaining rollers, by which means the rove receives the requisite degree of draught for the yarn intended to be spun. The drawn rove now passes through guides, and through the top of the spindles G, and thence through the flyer, then on to the bobbin; the revolution of the flyer giving the thread the proper degree of twist. The ends are seen hanging from the bobbin rail, which

are designed to increase the friction of the bottom of the bobbin on the rail, so that it may not be turned too rapidly round by the spindle. The bobbin rail and spindle are put in motion in the same way as they are in the roving frame. The connexion of the wheel work may be seen by inspecting fig. 2.

Such is the construction of the flax-spinning frame in use for yarns of the coarser kind; when fine yarns are to be spun, a modification of the spinning frame becomes necessary. The distance between the drawing and retaining rollers ought to be made much less than the proportion given in the engraving, and the rove, before it passes through the retaining rollers, is led through a trough of water, kept hot by steam. The trough is placed about the height B B in the front view, the rove being led through the water by passing under two smooth brass wires, one on the front, and another on the back of the trough. In wet spinning likewise, the bobbins on the rail A are set on upright spindles instead of horizontal pins.

We have now considered the machinery employed in the manufacture of linen yarn with as much minuteness as the nature of this work will admit; but before dismissing the subject, it is necessary that we should show in what manner the tow is treated, which, we stated, was separated from the flax during the first process, heckling.

The tow being taken from the heckles is carried to the carding engine. In plate 50, fig. 1, is an end view of the wheel gearing; fig. 2, a view of the beltting; and fig. 3, a front elevation of the tow carding engine. The tow is laid on the spreading table and made to pass between the feeding rollers A A, carried round the large cylinder O, below the back clearer B, over the top of the worker C, then between the top clearer D and the cylinder, then, being carried round the worker E, it passes between the finisher F and the cylinder. The tow is then carried off by the doffer G, received by the drawing rollers H H, from which it is passed through the delivering rollers I I into a can. The can is now carried to the finisher card, and passed through it, the two cards being exactly similar in construction. By the second carding, the tow is drawn into a much finer sliver than it is in the breaker, or first carding, and is thus prepared for the roving frame.

The tow-roving frame is similar in construction to the flax-roving machine, with this exception, that the gills, or heckles, are not connected in a chain, but in a cylinder, the gills rising and falling as it revolves, by means of guides at the ends of the cylinder. The tow-roving frame is shown in end elevation, fig. 4; and front elevation, fig. 5, plate 50.

The spinning of tow is performed in a machine constructed in the same way as the flax-spinning frame, but larger and stronger.

A steam engine of twenty horses' power will drive for the flax department,

- 9 Spreading machines,
- 14 Drawing frames,
- 22 Moving spindles,
- 350 Spindles for spinning.

#### In the tow department—

- 1 Treader, } Machines for preparing the tow
- 1 Shaker, } for the carding.
- 2 Breaker cards,
- 4 Finisher cards,
- 10 Silvers of drawing,
- 20 Spindles of roving,
- 100 Spindles of spinning.

Each spindle will produce about half a spindle of yarn per day.

The drawings, from which the plates that accompany this article have been engraved, were kindly furnished to us by P. Herrie, Esq., Taylors, Dun-

— See the description of the Flyer in page 663, vol. II, of the Encyclopædia.

dee, and were taken from machines in actual preparation by him.

For an account of the formation of linen cloth, see *Weaving*.

LING; a species of marine fish, belonging to the great genus *gadus*. It is from three to four feet in length, and somewhat like the pike in shape. This fish abounds on the coasts of Great Britain, where it has long formed an important branch of trade. It is in perfection from the beginning of February to May; in June, the spawning season commences. When in season, its liver abounds with an oil of excellent quality and flavour; but when it becomes out of season, this organ assumes a red colour, and contains but little oil. This oil is procured by subjecting the liver to a slow fire, otherwise a very small quantity is obtained. According to the English law, such of these fish as are cured for exportation, must measure twenty-six inches from the shoulder to the tail; otherwise they are not entitled to the bounty granted for the encouragement of this trade. There is another species of ling, the eel-pout (*G. lota*), which is from one to two feet long, of a yellow colour, variegated with brown. This is the only species of the genus which is found in fresh water. It abounds in the lake of Geneva. It is amazingly prolific, 128,000 ova having been counted in a single female. It is much esteemed as an article of food, and its liver, which is very voluminous, is highly prized by epicures.

LINGAM; the symbol of the creating and producing power, sacred among the Indians and Egyptians. See *Indian Mythology*.

LINGUA FRANCA; a corrupt Italian, mixed with other words, the dialect spoken between the inhabitants of the coast of North Africa and the Levant and the Europeans. It is, in fact, the Creole of the Mediterranean, and is extremely useful for a traveller in those countries. It is easily learned by one who knows Italian, and still more easily understood.

LINGUA GERAL; a corrupted Portuguese, spoken on the coast of Senegambia.

LINGUET, SIMON NICHOLAS HENRY; a French historical and political writer, was born in 1736, at Rheims, where his father, who had been professor at the college of Beauvais, was living in a kind of exile, having been banished by a *lettre de cachet*, on account of his participation in the Jansenistic controversy. This circumstance was the origin of Linguet's saying "that he was born under the auspices of a *lettre de cachet*." Having studied law at Paris, in the same college where his father had been professor, and having obtained the three first prizes of the university in 1751, he attracted the notice of the duke of Deux-Ponts, who was at that time in Paris, whom he accompanied on a journey to Poland. Linguet soon returned to his own country, and, on the breaking out of the war between France and Portugal, went to Spain as secretary to the prince of Beauvau. He there made himself acquainted with the Spanish language and literature, and, during his stay at Madrid, he published translations of some of the works of Calderon and Lope de Vega. His first historical attempt, *Histoire du Siècle d'Alexandre*, which was dedicated to the king Stanislaus Leszcinski, was published immediately after his return to Paris. His brilliant oratorical powers, and his thorough acquaintance with the law, gave him a great reputation at the bar, but, at the same time, his severe remarks and bold ideas created him many enemies. His controversy with D'Alembert, who at that time had almost the entire control of the academy, prevented him from becoming a member of that body. His fame as an author and lawyer, however, increased, and several cases conducted with

great ability, such as that of the duke d'Angoulême against the government, and the criminal case of the count de Morangres, on which he wrote an excellent treatise, raised him to high consideration, and at the same time excited the jealousy of his countrymen, whom he increased to such a degree, by one of his diatribes, that they formed a sort of conspiracy against him, binding themselves not to pass on him. Even the parliament became engaged in these disputes, and Linguet, whose reports and remarks increased in bitterness, was struck from the list of parliamentary advocates. As a political writer he succeeded no better. His *Journal patriotique* commenced in 1777, offended the prime minister, M. de Breteuil, and was suppressed. Linguet, thinking his personal freedom endangered, went to Germany, Holland, and England. He afterwards went to Brussels, until M. de Vergennes procured him a permission to return to France; but, his advisers finding some new cause of complaint, he was sent into the Bastille by means of a *lettre de cachet*, where he remained above two years, and was then sent to Reibel for a short time, 1785. He went again to London, and there published a work against arbitrary power, to which he had fallen a sacrifice, as well as he had himself defended in an earlier work, *Des Lois*. He afterwards continued his *Journal politique* at Brussels, and flattered with a new address, the emperor Joseph II., who was displeased with his memoir on the navigation of the Scheldt, that the emperor gave him 1000 ducats, with letters of nobility. But having taken the part of Van der Noot and of the Brabant insurgents, he was ordered by Joseph to leave the Netherlands. In 1791, he again appeared in Paris, and pushed for the negroes in St Domingo at the bar of the convention. At a later period, he became an object of suspicion to the terrorists, and his attempt to escape having failed, he was arrested, June 27, 1794, and condemned to death by the revolutionary tribunal, for having, according to the sentence, "served the despots of Vienna and London. His writings are numerous. Of Linguet's works on history, politics, political economy, and the law, we mention only his *Histoire des Révolutions de l'Empire Romain*, from Augustus to Constantine; *Restitution des Philosophes*; *Théâtre Espagnol*; *Lettre sur la Théorie des Lois*; *Mémoire pour le Duc d'Aiguillon et le Comte de Morangres*; *De la Liberté de Gouvernement*; *Mémoires sur le Brabant*, and particularly his *Annales politiques civiles, et littéraires du 18 Siècle*, which contain much important matter for the political and literary history of the time.

LINLITHGOW, an ancient royal burgh of Scotland, the capital of Linlithgowshire, is situated sixteen miles west from Edinburgh, and thirteen north-east from Glasgow. The town consists of a single street, half a mile in length, and broad and convenient, except that part immediately to the east of the cross. Many old houses have, of late years, been replaced by handsome new buildings. At the north side of the town is the site of the royal palace, a large quadrangular building, with towers at the corners, and a court in the interior, on the other side of which was a large hall, or the remarkable Scottish parliament. This monument of royal magnificence is now in ruins, having been burned by the English dragoons in 1746, on their accession to the battle of Falkirk. Among the public buildings are the town-house and prison, with a court-yard, built in 1608; and a conduit or fountain, beautifully rebuilt in 1807. The chief manufactures are those of tanned leather and shoes, both on a small scale; in the vicinity are *etc. etc.*

In the reign of David I., there was a *etc. etc.*

and grange at Linlithgow, whence the town originated; and it was the frequent residence of the court in the sixteenth century, when it became the scene of some remarkable events. In St Mary's aisle of the principal church occurred the supposed apparition of St John to James IV., to warn him of his approaching fate at the battle of Flodden Field, as related by the historian Lindsay, of Pitcottie, and introduced by Sir Walter Scott into his poem of "Marmion." Mary queen of Scots was born in the royal palace here, December 8, 1542. In one of the streets it still shows the gallery, whence the Regent Murray was shot at and killed, as he was passing through the town on horseback, by Hamilton of Bothwellhaugh, in 1570; and at Linlithgow the "Solemn League and Covenant" was publicly burned in 1662. Several royal charters were granted to this town. Population of burgh and parish in 1831, 4,874.

**LINLITHGOWSHIRE, or WEST LOTHIAN,** a county of Scotland, lying on the south shore of the Firth of Forth, having Edinburghshire on the east and south-east, Lanarkshire on the south-west, and West Lothian on the west. It is about twenty miles in length, and twelve in breadth. The soil of this county is in general a rich and fertile loam. Coal and limestone abound; ironstone is also to be found in some parts of the shire. A vein of lead ore was discovered in the reign of James VI., so richly impregnated with silver, that it was sufficiently profitable to be worked for the sake of the silver which it furnished. Volcanic appearances occur in several places, or at least such an arrangement of rocky strata, as some geologists usually attribute to the action of volcanic heat; thus particularly at Dundas Hill, in the parish of Dalmeny, there is a bold mass of basaltic rocks, displaying occasionally in their structure regular basaltic columns. There are many handsome noblemen's and gentlemen's seats in various parts of Linlithgowshire, among which the more distinguished are Hopetoun House, the earl of Hopetoun's magnificent residence; Harbottle Castle, belonging to the earl of Roseberry; Calder House, the seat of lord Turphichen; Craigie Hall, and Dundas Castle. The two royal burghs are Linlithgow and Rosendene; the other principal towns are Horncastle, Whitburn, Rathgate, and Kirkliston. Population of the county in 1831, 23,201.

**LINN, JOHN BLAIR,** an American poet, was born March 14, 1777, at Philadelphia, Pennsylvania. His poetical talents displayed themselves while he was yet a youth at Columbia college, New York, and, before he had reached his seventeenth year, a volume of his effusions, both in prose and verse, was published. After finishing his collegiate course, he commenced the study of law, at the age of eighteen, with general Hamilton, but continued in his office very about a year, during which time, he brought a tragedy, called Hourville Castle, upon the stage, with success. Having removed to Schenectady, and received strong religious impressions, to which he had always been inclined, he entered upon the study of theology, and, in 1798, he was licensed to preach, and soon became distinguished for pulpit eloquence. He was installed pastor of the first Presbyterian church in Philadelphia, in June, 1799. The duties of this situation he discharged for the two subsequent years, in a manner consistent with the fervour of his piety and the excellence of his mind. He continued, however, to cultivate his poetical talents. His *Powers of Genius*, a didactic poem of considerable length, experienced flattering success, and in a few months reached a second edition. In the same volume which it were printed various minor pieces. A controversy in which he became engaged with doctor Priestley, was engendered by a publication of the

latter on the merits of Socrates, which were placed before those of Jesus Christ. The religious feelings of Mr Linn prompted him to answer the doctor's pamphlet, which he did in a manner worthy of his cause. The last work on which Mr Linn employed his leisure hours, was a narrative poem, published by his friends, under the title of *Valerian*, after his death, which took place August 30, 1804.

**LINNÆAN SOCIETY;** a society in London, instituted in 1788, by Sir J. E. Smith, and incorporated in 1802, for the promotion of the study of natural history.

**LINNE, CHARLES,** but more generally designated by his Latinized name, *Linnaeus*, the most celebrated naturalist of his age, was a native of Sweden. He was the son of a clergyman, and was born May 13, old style, 1707, at Roshult, in the province of Smaland. His father was fond of gardening, and his little domain was stocked with plants not commonly cultivated—a circumstance to which the prevailing taste of the son may be fairly attributed. He was sent to the grammar school, and afterwards to the gymnasium of Wexio, to be educated for the ministry; but, as he disliked the studies of the school, and preferred to collect plants and catch butterflies, he remained behind his fellow-pupils in Latin and Greek, and the teachers declared to his father that he was only fit for a mechanic. The father sent him to a shoemaker; but the physician Rothmann, having discovered talents in the boy, induced his parents to let him study. As botany afforded him no prospect of a support, Linne was obliged to study medicine. In 1727, he entered at the university of Lund in Scania, whence he removed, the following year, to Upsal. During his early residence there, the narrowness of his father's circumstances exposed him to great difficulties, from which he was relieved by the patronage of Celsius, the theological professor, an eminent naturalist, who had become acquainted with him in the botanical garden at Upsal, and through whose recommendation he obtained some private pupils. He also formed a friendship with Artedi, a medical student like himself, devoted to the cultivation of natural history. He now, in his twenty-fourth year, conceived the idea of a new arrangement of plants, or the sexual system of botany, relative to which he wrote a memoir, which was shown to Rudbeck, the botanical professor, who was so struck with its ingenuity, that he received the author into his house, as tutor to his sons, and made him his assistant in the office of delivering lectures. Forty years before, Rudbeck had made a journey to Lapland, which excited the curiosity of the learned. A new journey was now concluded upon, and in 1732, Linne was sent by the academy of sciences at Upsal, to make a tour through Lapland, from which he returned towards the close of the year. Fifty Swedish dollars were thought sufficient by Linne to defray his expenses, and with this small sum he made a journey of more than 3500 miles, unaccompanied. In 1733, he visited the mining district around Fahlun, and gave lectures on mineralogy, having formed a system of that science, afterwards published in his *Systema Nature*. While he was thus adding to his reputation at Upsal, he became involved in a violent quarrel with the medical professor, Nicholas Rosen, who seems to have acted with a great deal of illiberality, and found means to prevent Linne from continuing his private lectures. He therefore engaged in a scientific tour through the province of Dalecarlia, and remained for some time at Fahlun, lecturing and practising medicine with considerable success. He again went to Lapland on a mineralogical tour, with seven young men; and, in 1735, published a complete *Flora* of this country—a classical work. In the

same year, he went to the university of Harderwyck, in Holland, and took the degree of M. D. He then visited Leyden, where the first sketch of his *Systema Naturæ* was printed in the form of tables, filling twelve folio pages. He became acquainted with John Frederic Gronovius, Boerhaave, and John Burman of Amsterdam; and he then published a work, entitled *Fundamenta Botanica*, exhibiting the basis of his botanical system. Mr Clifford, a rich merchant of Amsterdam, made him superintendent of his garden at Hartecamp, near Haerlem, rich in curious exotics, of which Linné drew up a systematic catalogue. In 1736, he made a visit to England. He returned to Holland with many new plants for Mr Clifford's garden, his description of which, entitled *Hortus Cliffortianus*, with thirty-seven plates, was now published in a most splendid form. He also published the first edition of his *Genera Plantarum*. In 1738, he made an excursion to Paris, and, towards the end of that year, returned to his native country, and settled as a physician at Stockholm. At first, he experienced neglect; but, through the influence of count Tessin, he was appointed physician to the navy, and had a salary for giving public lectures on botany in the summer, and on mineralogy in the winter. The establishment of the royal academy of Stockholm, of which he was one of the first members, contributed to the advancement of his reputation, by the opportunities which it afforded for the display of his abilities. In 1741, he succeeded Roberg in the professorship of medicine at Upsal, to which was added the superintendence of the botanic garden, to the new arrangement and augmentation of which he devoted much of his time and attention. In 1745, appeared his *Flora Suecica*, and the next year his catalogue of Swedish animals, entitled *Fauna Suecica*. He was elected to the post of secretary of the academy of sciences at Upsal. In 1746, an honorary medal of him was struck at the expense of some noblemen; and, in 1747, he was nominated royal archiater. Through his influence, many young naturalists were sent to explore various countries; and to his seal in the cause of science we owe the discoveries in natural history made by Kalm, Osbeck, Hasselquist, and Loeffling. He was employed by the queen of Sweden to describe her museum at Drottningholm, when he made a new scientific arrangement of the shells contained in it. About 1751, he published his *Philosophia Botanica*, and, in 1753, his *Species Plantarum*, containing a description of every known plant, arranged according to the sexual system. This work of Linné, which Haller terms his *Maximum Opus et Æternum*, appeared originally in two volumes 8vo.; but the edition published by Willdenow at Berlin, 1799—1810, is extended to ten volumes. In 1753, this great naturalist was created a knight of the polar star—an honour never before bestowed on a literary man. In 1761, he was elevated to the rank of nobility. Literary honours were also conferred on him by scientific societies in foreign countries. In 1768, he completed the plan of his *Systema Naturæ*, which, through successive editions, had been enlarged to three octavo volumes. Linné acquired a moderate degree of opulence, sufficient to enable him to purchase an estate and mansion at Hammarby, near Upsal, where he chiefly resided during the last fifteen years of his life. There he had a museum of natural history, on which he gave lectures, and to which he was constantly making additions, from the contributions of travellers and men of science in various parts of the world. His health, during a great part of his life, enabled him to pursue his researches with vigour and activity; but in May, 1774, he had an apoplectic attack, which obliged him to relinquish the most laborious part of his professorial duties, and

close his literary labours. A second attack occurred in 1776, and he afterwards experienced a third; but his death did not take place till January 11, 1778. Besides his works on natural history, he published a classified *Materia Medica*, and a systematic treatise on nosology, entitled *Genera Morborum*. Few men in the history of science have shown such boldness, seal, activity, and sagacity as Linné: natural science is under unspeakable obligations to him, though the different systems established by him may be superseded by more perfect ones. Charles XIV., king of Sweden, in 1819, ordered a monument to be erected to him in his native place. By his wife, the daughter of a physician at Fahlun, he had a son and four daughters. The former, *Charles von Linné*, was joint-professor of botany, and afterwards of medicine at Upsal. He was well acquainted with science, but distinguished himself by no discoveries of importance. On his death, without issue, in 1783, the family became extinct.—*Elizabeth Christina von Linné*, one of the daughters of the great naturalist, studied botany, and became known by her discovery of the luminous property of the flower of the *tropæolum*, of which an account was communicated to the academy of Stockholm.

#### LINSEED OIL. See *Flax*.

LINT, in surgery, is the scrapings of fine linen, used by surgeons in dressing wounds. It is made into various forms, which have different names, according to the difference of the figures. Lint, made up in an oval or orbicular form, is called a *plastr*; if in a cylindrical form, or in shape of a disk or oval stone, it is called a *dosril*. These different forms of lint are required for many purposes; as, 1. to stop blood in fresh wounds, by filling them up before the application of a bandage; though, if scraped lint be not at hand, a piece of fine linen may be torn into small rags, and applied in the same manner; in very large hemorrhages, the lint or rags should be first dipped in some styptic liquor, as alcohol, or oil of turpentine, or sprinkled with some styptic powder. 2. to agglutinate or heal wounds; to which end lint is very serviceable, if spread with some digestive ointment, balsam, or vulnerary liquor: 3. in drying up wounds and ulcers, and forwarding the formation of a cicatrix: 4. in keeping the lips of wounds at a proper distance, that they may not hastily unite before the bottom is well digested and healed: 5. they are highly necessary to preserve wounds from the action of the air.—Surgeons of former ages used compresses of sponge, wool, feathers, or cotton, linen being as plentiful than in later times; but lint is far preferable to all these, and is, at present, universally used.

LINTZ, the capital of Upper Austria, on the Danube, at the influx of the Traun, is well built, with a bridge 400 paces long, and has, exclusive of the garrison, a population of 18,700 inhabitants, houses, 1000. Here is the largest woollen manufactory in Austria, in which fine carpets are made. Much gunpowder is also manufactured here. In 1784, Lintz was made a bishop's see. In 1674, the lyceum was founded by Leopold, and, in 1834, institutions for the deaf and dumb, and one for the blind, were erected. The Northern Institute is a chapel for the Catholics of the north of Germany. Lon. 17° 16' 45" E.; lat. 48° 18' 54" N.

LINUS; the name of a celebrated musician of antiquity, to whom Diodorus Siculus, quoting Dampsius of Mitylene, attributes the introduction of verse and music into Greece. He was a native of Chios, and to him are ascribed a poem on the exploits of Bacchus in India, a treatise on mythology, the addition of a string to the lyre then in use, and the invention of melody and rhythm. Suidas also joins in giving him credit for the last-mentioned improvements, and calls him the first lyric poet. A few

fragments of poetry, under his name, are to be found in Stobæus.

**LION** (*felis leo*). The lion, like all other cats, is armed, in each jaw, with six strong and exceedingly sharp cutting teeth, two formidable canine, and six others, occupying the usual place of the molars, but differing from these by terminating in sharp protuberances. Besides these, there is a small tooth, or tubercle, on each side of the upper jaw, immediately posterior to all the others. The tongue is covered with rough and elevated *papillæ*, with their points directed backwards. The claws, which are five in number on the fore feet, and four on the hinder, are of great length, extremely powerful, and much curved; like those of the other cats, they are retractile within a sheath enclosed in the skin covering the paws. The lion is distinguished from his kindred species by the uniformity of his colour, which is pale tawny above, becoming somewhat lighter beneath, and never, except while very young, exhibiting any markings; and also by the long and flowing mane of the old male, which, covering the whole head, extends backwards over his shoulders. Notwithstanding the praises that have, from time immemorial, been bestowed on this animal, for grateful affection, dauntless courage, and merciful forbearance, he is nothing more, in moral and intellectual faculties, than a cat of immense size and strength, and endowed with all the guileful and treacherous qualities of that treacherous tribe. His dauntless courage is a mere consciousness of superiority over the animals by which he is surrounded, and wholly disappears in the neighbourhood of man; his merciful forbearance is nothing more than that he never destroys more than satiates his hunger or revenge, and that, when under the dominion of man, he suffers his keeper to approach him without injury.

The lion is only met with in the warmer regions of the old world, and more particularly of Africa, in whose vast forests and arid deserts he reigns supreme and uncontrolled. He is met with, but rarely, in parts of India, Arabia, and Persia, but his range in these countries is becoming very limited. From Libya, whence the Romans obtained so many, he has almost disappeared; and in classic Greece, where, we are informed by Aristotle, he once occurred, none are to be found. In America, this species never occurred, its place being supplied by the puma. Naturalists have differed greatly as to the longevity of this animal. Buffon stated it to be from twenty to twenty-two years; but it far exceeds this, as the one in the Tower of London, which died in 1760, lived in captivity above seventy years; and another died in the same place, at the age of sixty-three. The lioness brings forth from three to four at a birth. The cubs, when first born, are about the size of a small pug dog, and continue to suck the mother for about a year. At this time, their colour is a mixture of reddish and gray, with a number of brown bands. The mane of the male begins to make its appearance when the animal is about three to three years and a half old. The male attains maturity in seven, and the female in six years. The strength of the lion is prodigious, a single stroke with his paw being sufficient to destroy most animals. The bone of the fore leg is remarkably fitted to sustain the great muscular strain so powerful an exertion occasions. Its texture is so compact, that it will strike fire with steel. The lurking-place of the lion is generally chosen near a spring, or by the side of a river, where he has an opportunity of surprising such animals as resort to the water to quench their thirst. Here he lies in wait, crouched in someicket, till his prey approaches, and then, with a prodigious leap, seizes it at the first bound: if, how-

ever, unsuccessful in this, he immediately retires to wait another opportunity. In the night, more particularly, the lion prowls abroad in search of his prey, the conformation of his eyes being, like those of the common cat, well fitted for seeing in a dim light. The roar of the lion is loud and terrific, especially when heard in the solitary wilds he inhabits; this roar is his natural voice; for, when enraged, he utters a short and suddenly repeated cry, whilst the roar is a prolonged effort, a kind of deep-toned grumbling, mixed with a sharp, vibrating noise. It has been usually stated, that the lion had constant and stated times for roaring, especially when in captivity; but this has been shown to be erroneous in some degree. It appears, however, that, in summer time, and especially before atmospheric changes, he uniformly commences about dawn; at no other time is there any regularity in his roar. When enraged, his cry is still more appalling than his roar; he then beats his sides with his tail, agitates his mane, moves the skin of his face and his shaggy eyebrows, thrusts out his tongue, and protrudes his dreadful claws. The lion requires about fifteen pounds of raw flesh a day; he drinks often, lapping like a dog; but in this process his tongue is bent downward: his breath is very offensive, and the odour of his urine insupportable.

There is some variation, in the lions of different countries in external appearance, though, in essential particulars, their habits are identical. The Asiatic variety seldom attains an equal size with the Cape lion; its colour is a more uniform and pale yellow, and its mane fuller and more complete, and being, moreover, furnished with a peculiar appendage of long hairs, which, commencing beneath the neck, occupy the whole of the middle line of the body beneath. Even the Cape lion presents two varieties, known as the *pale* and the *black*, distinguished, as their appellations imply, by the lighter or darker colour of their coats. The latter of these is the larger and more ferocious of the two. The Barbary lion has the same full mane as the Asiatic, but exceeds him in size.

The number of lions, as has been observed, has greatly diminished, judging from the multitudes spoken of by ancient writers, and those carried to Rome. Thus Sylla the dictator exhibited, during his prætorship, 100 of these animals; and Pompey presented 600 in the circus. Lion fights were common under the consulate, and during the empire. Adrian, it is said, often caused 100 to be destroyed at one exhibition; and Antoninus Pius and Marcus Aurelius were equally prodigal in gratifying the people. At the Cape of Good Hope, lions are hunted, not only for the purpose of extermination, but also for their skins. In the daytime, and in an open country, from ten to sixteen dogs will easily overcome a lion of the largest size; nor does there appear to be any necessity that the dogs should be very large; as he is less swift than these animals, they readily overtake him, on which the lion turns round, and waits for the attack, shaking his mane, and roaring in a short and sharp tone, or sits down on his haunches to face them. The dogs then surround him, and simultaneously rushing upon him, subdue him by their united efforts, though not before he has destroyed several of them. But the mode of destroying them, usual among the Bushmen, is by shooting them, either with fire-arms or poisoned arrows. The inhabitants know that the lion generally kills and devours his prey at sunrise and sunset. On this account, therefore, when they intend to hunt them, they notice where the antelopes are feeding at daybreak: if they perceive that these animals are alarmed, they conclude that they have been attacked

by a lion. Marking the spot whence the alarm took place, about mid-day, when the sun is very powerful, and the object of their attack asleep, they carefully examine the ground, and, if they find him, they lodge a bullet or poisoned arrow in him. Sometimes, however, he is fairly brought to bay in the daytime, by the hunter, as the following account from Pringle testifies. After his retreat is found, "the approved plan is to torment him with dogs till he abandons his covert, and stands at bay in the open plain. The whole band of hunters then march forward together, and fire deliberately, one by one. If he does not speedily fall, but grows angry and turns upon his enemies, they must then stand close in a circle, and turn their horses' rear outward, some holding them fast by the bridles, while the others kneel to take a steady aim at the lion as he approaches, sometimes up to the very horses' heels, crouching every now and then, as if to measure the distance and strength of his enemies. This is the moment to shoot him fairly in the forehead, or some other mortal part. If they continue to wound him ineffectually, till he becomes furious and desperate, or if the horses, startled by his terrific roar, grow frantic with terror, and burst loose, the business becomes rather serious, and may end in mischief, especially if all the party are not men of courage, coolness, and experience." Very full accounts of the lion and his habits are to be found in the travels of Sparmann, Barlow, Levaillant, Burchell, &c., in Southern Africa, and also in the Library of Entertaining Knowledge, and the Tower Menagerie, from which the above account has been condensed.

**LION'S GULF.** This is the proper spelling of the gulf generally called *Gulf of Lyons*. The name is derived from *lion*, on account of the fierceness of the gales, at some seasons, in this gulf. The proper mode of writing it in French is *Golfe du Lion*. See *Lyons, Gulf of*.

**LION'S SHARE**; the whole, or a disproportionate share of the advantages of a contract, claimed by one of the parties, and supported by the right of the strongest. The phrase is derived from a fable of Æsop.

**LIPARI**; a cluster of volcanic islands in the Mediterranean, which take their name from the principal one of the group, about twenty-four miles from the north coast of Sicily. Lon. 15° 12' E.; lat. 38° 34' N.; population, about 20,000. These islands were called, by the ancients, *Æolia*, *Vulcania*, and *Insula Liparaeorum*, and feigned to be the residence of Æolus and Vulcan. *Lipari*, the largest, is populous and well cultivated, producing great quantities of corn and fruit, especially figs and raisins; it likewise produces alum, sulphur, nitre, and cinnabar. It is about fifteen miles in circumference; the air is healthy, and the inhabitants industrious and good seamen. On the eastern coast is situated a town of the same name. In this island were formerly pits, which emitted fire and smoke, but have long ceased to do either. Population, 15,000; square miles, 100. The other islands are Stromboli, Panaria, Vulcano, Salini, Alicudi, and Felicudi, with two or three smaller ones. The volcanic eruptions, formerly frequent in the island of Lipari, ceased in the sixth century, but the whole island is composed of pumice-stone, lava, volcanic glass, and black sand; and the warm baths, and heated vapours of the Stoves (excavations which emit hot, sulphureous exhalations), prove the activity of the subterranean fires. The celebrated crater of Vulcano was visited by general Cockburn in 1812 (*Voyage to Cadix*); the volcano is probably only slumbering, and not extinct. Stromboli is at present the most remarkable of the islands; its fires are in unremitting activity, the eruptions taking place

at regular intervals, varying from three to eight minutes. See the works of Dolomieu, Spallanzani, Brydone, &c.

**LIPOGRAMMATIC COMPOSITIONS**; those in which certain letters are purposely left out. Thus Lope de Vega wrote a *novella* without *l* or *e*. Katschub wrote one without *r*. The word is derived from the Greek *λυπος* (signifying *to omit*, and *gramma* many compound words), and *γραμμα* (letter).

**LIPPE.** The ancient principality of Lippe is at present, divided between two reigning houses: 1. *Lippe-Deimold* contains about 490 square miles, with 71,200 inhabitants. Deimold, with 2700 inhabitants, is the capital. Public revenue, 490,000 guilders. The prince furnishes a contingent of 600 men to the German confederacy. The constitution granted by the mother of the present prince to the country is still suspended, because the nobility will not allow the peasants to be represented. 2. *Schaumburg-Lippe*. The dominions of the prince of Lippe-Schaumburg contain 212 square miles, with 25,538 inhabitants; revenue, 215,000 guilders; conscript to the Germanic confederation, 240 men. Bielefeld, the capital, is on the river Aa. In 1540, the prince abolished the last traces of bondage, and Jan. 15, 1816, established a constitution.

**LIPPI.** There were three Florentine artists of this name. Of these, the eldest, *Francesco Lippi*, born in 1421, and surnamed *the Old*, had taken the vows as a Carmelite monk, but afterwards abandoned the church, and underwent many vicissitudes of fortune. On one occasion, he fell into the hands of a Barbary corsair, who sold him to slavery in Africa. The successful exertion of his talents, upon the portrait of his purchaser, was rewarded by his restoration to liberty. On his return to Italy, he was received into the service of the grand duke of Florence. His death took place in 1488; and, although he was then sixty-seven, it is said to have been the result of an intrigue with a female of a respectable family, poison being employed by her relatives in his destruction.

He left one son, *Filippo*, also a painter of considerable reputation, born in 1460. Many of his works are yet to be found in the city of which he was a native. He died in 1505.

*Lorenzo*, the third of the name, descended of the same family, united to considerable skill as an historical and portrait painter the arts of poetry and music. He was born in 1606, and is advantageously known as the author of a burlesque poem, entitled *Macinabile Racquistato*. Of this work there have been three editions; two printed at Florence, in 1688 and 1713, the other, in 1768, at Paris. It appeared originally under the fictitious name of *Zipoli*. His death took place in 1664.

**LIPSIUS, JUSTUS**; an acute critic and erudite scholar of the sixteenth century, was born at Weversche, in Brabant, a village situated between Brussels and Louvain, in October, 1547. Marcus Lipsius, the intimate friend of Erasmus, was his uncle. His genius developed itself very early to memory being considered wonderful. Before he had completed his ninth year, he had written some miscellaneous poetry, much above mediocrity. He was instructed at Brussels, and, subsequently, in the colleges of Æth, Cologne, and Louvain. He removed to Rome in his twentieth year, and, having secured the patronage of cardinal Gravellina, by dedicating to him his treatise *Variarum Lectionum*, was received into his household, in the nominal capacity of secretary. With this distinguished prelate he remained till 1569, sedulously consulting the treasures of the Vatican, and other principal libraries, especially employing himself in the collation of rare and ancient

manuscripts. On his return to the Netherlands, after a short time spent at Louvain, he visited the capital of the German empire, and then accepted a professorship in the university of Jena. Here the fickleness of his disposition, and the vacillating state of his opinions respecting religious matters, which eventually fixed the imputation of imbecility on a character in other respects estimable, first became apparent. He renounced the Romish church, and became a Lutheran; but, quitting Jena, at length, with an avowed intention of spending the remainder of his life in retirement in his native country, he repaired to Overysche, and, soon after, recanted his supposed errors, and became reconciled to the see of Rome. In 1577, however, he again removed to Leyden, when he embraced the doctrines of Calvin, and, during the thirteen years which he spent in that university, gave to the world the most esteemed of his works. In 1590, he returned finally to Louvain, and once more became a Catholic, and that of the most bigoted description. Many tempting and honourable offers were made him by various potentates, to engage him in their service; but he refused them all: and, at length, died at Louvain, in the spring of 1606. Superstition led him, a short time before his death, to dedicate a silver pen, and his fur gown, to the virgin Mary. His principal works are the *Variae Lectiones* above-mentioned; an excellent Commentary on the Works of Tacitus; treatises *De Constantia*; *De Militia Romana*; *De Amphitheatris*; *De Pronunciatione recta Linguae Latinae*; *De Cruce*; *De una Religione*; *De Bibliothecis*; *Satira Menippaea*; *Saturnalia*; and an Oration on the Death of the Duke of Saxony. The best edition of them is that printed at Antwerp, in 1637.

**LIQUEUR** (from the *French*); a palatable spirituous drink, composed of water, alcohol, sugar, and some aromatic infusion, extracted from fruits, seeds, &c. The great difference in the qualities of the different *liqueurs* is owing principally to a variation in the proportions of the sugar and alcohol. The French distinguish three qualities: the first are the *ratasias*, or simple *liqueurs*, in which the sugar, the alcohol, and the aromatic substance are in small quantities: such are the anise-water (q. v.), *noyau*, the apricot, cherry, &c. *ratasias*. The second are the oils, or the *fine liqueurs*, with more saccharine and spirituous matter; as the *anisette*, *curacao*, &c., which are those commonly found in the *cafés*. The third are the *creams*, or superfine *liqueurs*, such as *rosoglio*, *maraschino*, *Dantico* water, &c. The same aromatic infusion may, therefore, give its name to *liqueurs* of different qualities, in which the materials are the same, but the proportions different: thus one proportion of ingredients gives *eau-de-noyau*; another *crème de-noyau*, &c.

**LIQUIDAMBAR STYRACIFLUA**, or SWEET GUM. This tree is widely diffused through America, from lat. 43° to Florida, and along the shores of the Gulf into the provinces of Mexico. The leaves, which somewhat resemble those of some maples, are very regularly five-lobed, and the lobes are serrated on the margin. The flowers are inconspicuous. The fruit consists of a sort of bur, supported on a long pedicel, and is somewhat similar to that of the cotton-wood, or plane-tree, but is much less even on its surface. It is abundant every where throughout the Middle, Southern, and Western States, and sometimes has a trunk five feet in diameter, with a proportional summit. The usual diameter, however, is from one to three feet. The wood is compact, capable of receiving a fine polish, and has been used for articles of furniture; but, for this purpose, it is inferior to either the wild cherry or black walnut. It is, however, employed for lining mahogany, for bed-

steads, and for a variety of purposes in the interior of houses, possessing great strength, but requiring protection from the weather. The bark, on being wounded, yields a small quantity of a fragrant resin.

**LIQUORICE** (*glycyrrhiza*); a genus of leguminous plants containing eight species. They have pinnated leaves, and small, blue, violet, or white flowers, which are disposed in heads or spikes, and are remarkable for the sweetness of the roots. The common liquorice (*G. glabra*) grows wild in the south of Europe, and is cultivated in many places, even in Britain, for the sake of the root, which is much used in pharmacy, and forms a considerable article of commerce. More than 200 tons of the extract are manufactured annually in Spain, a considerable portion of which is sent to London, and employed in the brewing of porter. It is often administered medicinally, in coughs and pulmonary affections, and the aqueous infusion is used as a refreshing beverage. A deep, light and sandy soil is best adapted to its culture.

**LIRIODENDRON.** See *Tulip-Tree*.

**LISBON** (*Lisboa*), the chief city of Portugal, and the residence of the court, is situated in the province of Estremadura, on the right bank of the Tagus, which is here a mile and a half in width, and not far from the mouth of the river. It is built on three hills, in a romantic country, and exhibits a grand appearance from the harbour. Including the suburbs Junqueira and Alcantara, it is about five miles in length, and a mile and a half in breadth. It contains forty parish churches, seventy-five convents, and a hundred chapels, 44,000 houses, and, before 1807, had 300,000 inhabitants, but, at present, has not more than 200,000; among whom are many foreigners, Negroes, Mulattoes, Creoles, and 30,000 Galicians, who come from Spanish Galicia, and serve as porters and water carriers, and perform other menial occupations. The town is open, without walls or gates. The highest hill only has a castle, now in ruins; but the harbour is beautiful, capacious, and safe, and is defended by four strong forts on the banks of the river (St Juliana, St Bugio, the tower of Belem, &c.). Many of the streets are very uneven, on account of the hilly situation of the city. The finest are on the banks of the river. There are no elegant private buildings. The houses of the nobility are distinguished only by their size. The western part has been beautifully rebuilt since the dreadful earthquake (Nov. 1, 1755) which destroyed half of the city, with the loss of 30,000 lives,\* the streets being straight, and regularly laid out, with fine houses and squares. The eastern part of the city, which was not affected by the earthquake, has preserved its gloomy aspect—crooked streets and old-fashioned houses, six and seven stories high. Lisbon was formerly known to be extremely filthy and unsafe; but, at present, regulations have been made to provide for the public security, and the streets are well lighted. Among the squares, the principal are the *Plaza do Commercio* and the *Rocio*. They are connected by handsome, wide, straight streets. The former, on which the royal palace, now in ruins, was situated, lies on the bank of the Tagus, as the landing-place of the harbour, is an oblong square, of 615 paces in length and 550 in breadth, and is surrounded, on three sides, with fine buildings (the fourth is open towards the

\* The city then contained about 150,000 inhabitants. The shock was instantly followed by the fall of every church and convent, almost all the large public buildings, and more than one fourth of the houses. In about two hours after the shock, fires broke out in different quarters, and raged with such violence, for the space of nearly three days, that the city was completely desolated. The earthquake happened on a holiday, when the churches and convents were full of people, very few of whom escaped.

river). In the centre there is a bronze statue of king Joseph I. The Rocio, where the *autos da fé* were formerly exhibited, is a regular oblong, 1800 feet in length and 1400 in width, with the new palace of the inquisition on one side. In this square ten streets meet. Among the churches, the new church is the finest, and is the most magnificent building erected since the earthquake. The patriarchal church, on an elevated situation, which affords a beautiful view, is magnificent in its interior, and contains rich treasures and many curiosities. The patriarch, the head of the Portuguese church, has a large annual income. The aqueduct, about seven miles in length, is a remarkable construction. The centre is so high, that a ship of the line might pass under it. The water is carried over the valley of Alcantara, on thirty-five marble arches. It withstood the force of the earthquake, although the keystones sank a few inches. The St Joseph's hospital, where 16,000 sick, and the foundling hospital, where 1600 children, are annually received, deserve to be particularly mentioned. Among the literary institutions are the royal academy of sciences, the college of nobles, the marine academy, with other seminaries, a botanical garden, three observatories, the royal cabinet of natural curiosities, and several public libraries, among which is the royal library, containing 80,000 volumes. Lisbon is the seat of the supreme authorities, and, of the patriarch of Portugal, with a numerous clergy. The inhabitants have but few manufactures: there are not even mechanics enough to supply the demands of the city. But Lisbon is the centre of Portuguese commerce, which extends to most of the countries of Europe, to America, and to the Portuguese possessions in other parts of the world. There are about 240 Portuguese and 130 foreign (principally British) mercantile houses. From 1700 to 1800 vessels arrive annually at the port (Junqueira). The beautiful environs of the town are embellished by a great number of country seats (*quintas*). In the vicinity are Belem and the castles Ramalhao and Quelus.

LISLE, or LILLE (Flemish, *Rijsel*); a large and strong city of France, formerly the capital of French Flanders, and now of the department of the North, situated on the Deule, in a dead flat. The Deule is navigable, and is divided into several branches, part of which supply the moats or great ditches of the citadel and town. The form of Lisle is an irregular oval; its length, from north-west to south-east, is nearly two miles; its breadth, about three quarters; its circumference, between four and five, exclusive of the earthen ramparts that surround the town, and which are, in their turn, surrounded by a moat. Lisle presents an imposing appearance, from its extent, its fortifications, its canals, its squares, and its public buildings. Few cities of France can vie with it in the straightness and width of its streets, the regularity of its buildings, and its general air of neatness. Several convents have survived the revolution; the hospitals are five, one very large. Lisle is a fortress of the first rank. Its citadel, the masterpiece of Vauban, is the first in Europe after that of Turin. It is a mile in circuit, and is surrounded by a double moat. The trade of Lisle is extensive. Its manufactures are of camlets, serges, and other woollen stuffs, cotton, calico, linen, silk, velvet, lace, carpets, soap, starch, tobacco, leather, glass, and earthenware. The origin of this town is ascribed by tradition to Julius Cesar. Louis XIV. took it from the Spaniards in 1667. It surrendered in 1708, to the duke of Marlborough and prince Eugene. At the peace of Utrecht, it was restored to France. In 1792, it was bombarded by the Austrians, who were obliged to retire, with the loss of 20,000 men. Po-

pulation, 69,860; 18 miles east of Tournay; lon. 7° 4' E.; lat. 50° 37' 50" N.

LIT; the enclosed ground wherein knights had their jousts and tournaments; so called because encircled with barriers as with a list. Some were double, one for each cavalier, so that they could not approach nearer than a spear's length. Hence to enter the lists is to engage in contest.

LISTEL; a small square moulding, serving to crown or accompany a larger, and to separate the flutings in columns.

L'ISTESSO TEMPO (*Italian*): a phrase implying that the movement before which it is placed is to be played in the same time as the previous movement.

LITANY (from the Greek *lithano*, *supplicatio*, prayer); a form of prayer or song, used on occasions of public calamity, first introduced, according to Zonaras and Nicephorus, by Proclus, about the year 446, at Constantinople, in the reign of Theodosius, according to Paulus Diaconus, under Justinian, at Antioch, in consequence of the following circumstance. An earthquake, says the legend, having driven the people into the fields, a boy was suddenly taken up into the air in their presence; but was again let down unhurt, on the people crying out *Kyrie eleison* (O Lord have mercy). The boy related he had heard the songs of the angels, "Holy God! Holy and Mighty Holy and Immortal! have mercy upon us!" and so gave rise to the litany. This kind of common prayer was, perhaps, not unusual among the Jews, and the 136th Psalm seems to have been adapted to this purpose. Litanies afterwards became very common, and every saint of the Roman calendar has his litany, it must be owned, that some of these are very unmeaning, enumerating all the names and miracles ascribed to the saint, and, in this respect, not unlike the prayers of the Romans, which consisted merely of a catalogue of the names of the deity addressed, against which St Paul gives a particular warning. Litanies are found in the old hymn-books of the Lutherae, but are no longer used by German Protestants. The Catholic litanies are distinguished into the greater and less. The latter is said to have been composed by bishop Mamertus, of Vienne (in France), in 468, when that place was visited by repeated calamities, the former by Gregory the Great, during an inundation of the Tiber, and a raging plague. This consisted of a song of seven choirs (hence *septiformis*, of clergy, monks, nuns, boys, girls, Roman citizens, and widows and married women. The litany probably consisted, at first, of the words *Kyrie eleison*, but was gradually enlarged. The litany was usually sung on the *dies rogationum* (days of entreaties). At a later period, the litany was not only addressed to the Holy Trinity, but also, as we have said, to the saints, and sung in processions. This latter kind of litany of course was omitted by the Protestants. The usual answer of the people is, *Ora pro nobis* (pray for us); if the litany is directed to the Virgin or a saint, or *Libera nos* (deliver us), if it is addressed to the Deity. Indecent parodies have often been made on litanies, and sung in connexion with other profane songs. In early times, instances occur of this being done, even by monks. (See the note to the article *Faust*, *Faust* of.) The following parody is taken from the *Canterbury's Letanie* (1647):

From too much keeping an evil devotion,  
From the manyfold treasons perjuramentum,  
From Oliver Cromwell, dur common madmen,  
Libera nos.

See the *Sacra Litania varia* (Astbury, 1644) and Bingham's *Origines Ecclesiasticae*, for a great variety of litanies.—That this simple form of prayer and response has, at times, been of great advantage to the people cannot be denied; and, because many litanies

are poor, all ought not to be condemned. See *Liturg.*

LITCHFIELD. See *Lichfield*.

LIT DE JUSTICE was formerly a solemn proceeding in France, in which the king, with the princes of the blood royal, the peers, and the officers of the crown, state and court, proceeded to the parliament, and there, sitting upon the throne (which in the old French language, was called *lit*, because it consisted of an under cushion, a cushion for the back, and two under the elbows), caused those commands and orders, which the parliament did not approve, to be registered in his presence. The parliament had the right of remonstrating, in behalf of the nation, against the royal commands and edicts. If the king, however, did not choose to recede from his measures, he first issued a written command (*lettres de jussion*) to the parliament; and if this was not obeyed, he held the *lit de justice*. The parliament was then, indeed, obliged to submit, but it afterwards commonly made a protest against the proceeding. Louis XV. held such a *lit de justice*, in 1763, in order to introduce certain imposts, but, on account of the firm resistance of the parliaments, he was finally obliged to yield. The last *lits de justice* were held by Louis XVI., in 1787 and 1788.

LITERARY HISTORY is the science whose object is to represent the development or the successive changes of human civilization, as far as these are manifested in writings, as the object of *political history* is to show the same, manifested in the various political establishments and changes. In a more limited sense, literary history treats of learned writings, their contents, fate, modifications, translations, &c. (which is *bibliography*, q. v.), of the lives and characters of their authors, the circumstances under which they wrote, &c. (which constitutes *literary biography*). The latter has also been called *external literary history*, the former *internal literary history*, because it aims to show, in a connected view, the development of sciences. From its nature, it is obvious that literary history could not fairly begin until mankind had acquired extensive knowledge of what has been done and written, which required the preparatory study of centuries, as well as a civilized intercourse among the various nations. This science is, indeed, of comparatively recent date, and we have it no means, even yet, a general literary history. What we have is mostly confined to Europe; at least, we are yet too little acquainted with many parts and periods of the literary history of the East, which has several times given an impulse to the western world, and authorize us to call what has hitherto been done a general literary history. The branch which relates to Greece and Rome must remain of surpassing importance. The ancients did not treat literary history as a distinct department of history. The literature of the Greeks, and, though not in the same degree, that of the Romans, were so intimately connected with their religion and politics, that a separation of literary from general history could not easily take place; besides, the materials were not sufficient to claim a separate consideration. Hence the classics contain only scattered notices and detached materials for a literary history, partly in biographies of poets, philosophers, orators, grammarians, &c.; partly in criticisms and extracts from their writings. In notices we find in the works of M. Terentius Varro, Cicero, Pliny, Quintilian, Aulus Gellius, Pausanias, Plutarch, Suetonius, Diogenes Laertius, &c. Suidas and Photius likewise contribute names and titles. The middle ages contributed detached facts to the history of their literature, partly in chronicles, partly in the confidential com-

munications of poets and other authors, respecting their own lives. The first rude attempt at a compilation of general literary notices, yet without systematical order, was made by Polydore Virgil of Urbino in his work *De Inventoribus Rerum*, which first appeared in print in 1499. The true father of literary history is the famous Conrad Gesner, whose *Bibliotheca Universalis* contains stores of knowledge not yet exhausted. In his twenty-fifth year, he began to execute his grand plan of a general work on literature, and, in three years, his materials were so far prepared, that they could be arranged for printing. According to his plan, the work was to be divided into three parts—an alphabetical dictionary of authors, a general systematic view of literature, which even cites single dissertations and passages, and an alphabetical index of matters and subjects treated. (See Ebert's *Bibliog. Lex.*, article *Gesner*). The first edition of the first division appeared in 1545.\* Peter Lambeck gave instruction in literary history at the gymnasium of Hamburg, 1656, on the plan of Gesner and Virgil, and published, in 1659, outlines, as a text-book for his lectures, the title of which is *Prodromus Historiæ Literariæ*. Daniel George Morhof's *Polyhistor Literarius, Philosophicus et Practicus*, the first edition of which appeared in 1688, contributed to promote the study of literary history. Since the beginning of the eighteenth century, literary history has been a favourite study of the learned, and has been taught in the universities, and in higher schools, at least in Germany. To these lectures we owe several Introductions, General Views, and Systems of literary history. We mention, in chronological succession, Burkhard Gotthelf Struvius, professor at Jena; Matthew Lobeltanz, professor at Greifswald; N. H. Gundling, professor in Halle; Gottlieb Stoll, professor in Jena; G. G. Zeltner, professor in Altorf; C. C. Neufeld, professor in Königsberg; F. G. Bierling, professor in Rinteln; and others. Reimann must also be mentioned on account of his Introduction to *Historia Literaria* (1708), and his *Idea Systematis Antiquitatis Literariæ*. Still more important was Chr. Aug. Heumann's *Conspectus Republicæ Literariæ*, a work much superior to any that had preceded it, in arrangement, acute criticism, and richness of materials. John Andrew Fabricius's *Sketch of a General History of Literature* (1752) is a comprehensive work, and unites the synthetic and analytic method. A. Y. Goguet was the first to introduce a more philosophical treatment of literary history; and the

\* Lord Bacon, in his *Advancement of Learning* (*De Aug. Sci.* ii. 5), seems to have been the first (1605) to have traced out the objects and extent of a general literary history (*Historia Literaria, Historia Literaria*). "History," says he, "is natural, civil, ecclesiastical and literary; whereof the first I allow to be extant, the fourth I note as deficient. For no man hath propounded to himself the general state of learning to be described and represented from age to age, as many have done the works of nature, and the state civil and ecclesiastical, without which the history of the world seemeth to me to be as the statue of Polyphemus with his eye out, that part being wanting which doth show the spirit and life of the person; and yet I am not ignorant that in divers particular sciences, as of the jurisconsults, the mathematicians, the rhetoricians, the philosophers, there are set down some small memorials of the schools, authors and books; and so likewise some barren relations touching the inventions of arts or usages. But a just story of learning, containing the antiquities and originals of knowledge, and their seeds, their inventions, their traditions, their divers administrations and managings, their flourishing, their oppositions, decays, depressions, obliivions, removes, with the causes and occasions of them, and all other events concerning learning, throughout the ages of the world, I may truly affirm to be wanting. The use and end of which work I do not so much design for curiosity or satisfaction of those that are lovers of learning, but chiefly for a more serious and grave purpose, which is, that it will make learned men wise in the use and administration of learning."

Italian Denina rivals him in brilliancy of manner, without equalling him in thoroughness and originality of views or in judgment. It began to be more and more clearly felt, that literary history, though an independent branch of history, would remain a mere list of names, titles, and dates, if it were not treated with constant reference to the state of religion, politics, morals, and the arts. Attempts have been made to treat it as a part of the general history of civilization by Iselin, Ferguson, Home, and particularly by Herder. In recent times, the Germans have taken the lead in this science, both in extent of knowledge and comprehensiveness of views. J. G. Eichhorn's, and L. Wachler's work is of high value, as are also those of S. G. Wald, J. G. Meusel, and Fr. Schlegel. It would exceed our limits were we to mention here the different productions upon the literary history of single nations and particular periods. A work on an extensive plan, though not of a general nature, is the great enterprise of the literary society of Göttingen—*History of Arts and Sciences in Europe, since the Restoration of the same, until the End of the Eighteenth Century*.

Literary history is naturally divided into ancient, middle and modern. The ancient terminates with the retirement of science into the convents, in the sixth century; the middle begins with the downfall of the great Roman empire (about 500 A. D.) and the commencement of literary civilization in the various European nations, without the support of ancient classical civilisation (see Berrington's *Literary History of the Middle Ages*); and the last begins about 1450, when the study of the classics was renewed, and knowledge revived in Europe.

**LITERARY PROPERTY.** In the whole compass and variety of the products of human labour, no one thing is more exclusively such than intellectual works. In the fabrication and production of almost all other subjects of value and property, the materials are supplied, directly or indirectly, by the earth or the water; and man only co-operates with nature in furnishing the article. But a piece of music, a painting, a poem, an oration, a history, or a treatise of any description, is the offspring of the unaided labour of the mind. It is supplied from abroad, only with the canvass, paper, parchment, or whatever other substance is used for recording the work, and affording the evidence of its accomplishment, but which is no more a part of the thing produced, than a deed conveying an estate, is a part of the thing conveyed. But, though the right to the products of intellectual labour is thus peculiarly positive and absolute, it is among the latest rights of property recognised in a community, since the subject of it, the product itself, is only the result of an advanced state of civilisation. Another reason of its not attracting a more early attention, is its abstract, incorporeal nature, and also, in some cases, the difficulty of defining and identifying it, and deciding what is an infringement of this right of property; and again, in some countries, speaking the same language as those bordering upon them, the great difficulty of protecting this kind of property from infringement, though no doubt arises as to the identification of the thing claimed, or in determining what shall be considered to be an infringement.

The question whether an author has, of common right, and independently of any special statute in his favour, a property in the products of the labour of his mind, as unquestionable and absolute as any other producer has in those of the labour of the hands, was very elaborately discussed in the court of king's bench, and in the house of lords, in the time of lord Mansfield, in the celebrated cases of *Millar* against *Taylor*, reported in the fourth volume of *Barrow's Reports*, in relation to the copyright of

*Thomson's Seasons*; and *Donaldson* against *Taylor*, reported in the same volume. The first of these cases came before the court in 1769. In 1709, the statute of 8 Anne, chapter 19, had been passed giving to authors an exclusive copyright "for the term of fourteen years, and no longer." Notwithstanding the limitation of the right to that term, by the statute, it had been held, in *divers cases*, subsequently decided, that the exclusive property of the author, or his representatives or assigns, continued after the expiration of the fourteen years, and, accordingly, in 1730, lord chancellor Hardwicke granted an injunction against a person, other than the proprietors, printing *Milton's Paradise Lost*, the title to the copyright of which was derived to the proprietor, under an assignment by *Milton*, twenty two years before. In the case relating to the copyright of *Thomson's Seasons*, three of the judges, namely, lord Mansfield, and justices Ashurst and Willes, were of opinion, that the exclusive right of property continued after the expiration of fourteen years from the first publication, as limited by the statute of Anne, and such was the decision of the court. Mr Justice Yates dissented from that opinion. Five years afterwards, in 1774, the other case came before the house of lords, and, as is usual with this tribunal, the opinion of the judges of the king's bench, common pleas, and exchequer, was taken. Lord Mansfield, being a member of the house, did not give an opinion in answer to the questions propounded by the house, with the other judges, but acted as voted as a member of the body. Of the eleven judges who gave opinions, eight were of opinion that an author had of common right—that is, as by the common law, or without any statute to that effect—the exclusive privilege of publishing his own works, and three were of a contrary opinion. Seven, against four to the contrary, were of opinion, that, by publishing his works and vending copies, he did not abandon his exclusive property to the public, or, in other words, that, by making and selling one copy he did not authorise all other persons to make, and use or sell as many copies as they might choose. This seems to be so plain a point, that, if four respectable judges had not been of a contrary opinion, one would be ready to say it admitted of no doubt.

A case very analogous, but much stronger in favour of the author's right of property, is stated in the public journals (1831), as having recently been decided in France. An artist had sold a *miniature picture*, the production of his own hand or pen, and the question was made whether the purchaser had a right to publish engravings of the original. It was decided, that the artist alone, and not the purchaser, had, in such case, the exclusive right to make and publish engraved copies. But, on the other question, proposed by the house of lords, viz. whether the statute of Anne took away the author's exclusive right to his own property, after the expiration of fourteen years, six of the judges were of opinion to the affirmative, so that the whole twelve judges were equally divided upon this question, lord Mansfield being, upon this and the two other questions, in favour of the author's right. But the house of lords decided that the author had no exclusive right after the expiration of the period limited in the statute, though the reasons given on that side, by the judges who supported it, are very unsatisfactory—and it is not easy to divine the grounds of the decision. Thus, while the poverty of authors and scholars—the great leaders and champions of civilisation and scientific advancement—has been proverbial all the world over, the government has interposed, or is constrained to have interposed, with its mighty arm, not for their protection and reward, but to despoil them of their pro-

perly, the fruits of their own labour, and sequester it for the public use. If a man cultivates the ground, or fabricates goods, the fruits of his labour go to him and his heirs or assigns, absolutely, for ever; but if he spends his life upon a poem or musical composition, he only has a lease of it for fourteen years, according to the statute of Anne, when it is to be forfeited to the public. This doctrine displays, in striking contrast, the rewards bestowed, and the forfeitures enacted, in reference to different species of glory and public service. While a military hero is rewarded with a grant of lands and a title of honour, to himself and his heirs *ad infinitum*, a man of equal genius, who, by his labours, instructs and delights mankind, and sheds a lasting glory upon the country of which he is a citizen, is despoiled of the fruits of his own labours. The injustice of such a doctrine is so obvious, that its legality, though sanctioned by an acquiescence of half a century, may well be questioned. However this may be, legislators have begun to mitigate the forfeitures heretofore inflicted upon literary eminence, by extending the time for which an author may enjoy the fruits of his own talents and industry. By a law passed in the fifty-fourth year of George the Third, chapter 156, an author is entitled to an exclusive copyright in his work for twenty-eight years, and, if he is living at the end of that period, it is continued during his life. This act is entitled to the commendation of being less unjust than that of Anne.

On the continent of Europe, the laws are much more favourable, or, rather, much less unfavourable, to authors. In France, they are entitled to an exclusive copyright during their lives, and their heirs or assigns for twenty years afterwards. In many of the German states, the right is perpetual, but it is subject to this disadvantage, that it extends only to the state, in which it is granted, and the work may be pirated in the others with impunity. This can be avoided only by procuring a copyright in the different German states, which is attended with much difficulty and expense. The defect of the laws of these German states on this subject, therefore, is not in confiscating the author's property, or refusing to recognise his right to it, but in burdening him with heavy expenses in securing its protection. In Russia, the period of the copyright is the same as in France, and it is not liable to be seized and sold for the payment of the author's debts. In the United States of America, the constitution provides, that congress may secure, "for limited times, to authors, &c., the exclusive right to their respective writings," &c. Under this provision, a law was passed, in 1790, giving to authors, being citizens of the United States, or being resident therein, the sole right of printing and vending their works for the term of fourteen years from the time of recording the title in the clerk's office; and, if living at the expiration of that period, and then citizens or resident as above, they could have a renewal of the exclusive right for fourteen years longer, on filing a copy of the title again in the clerk's office. This law also required, that, at the commencement of each term, the author should publish the clerk's certificate in some newspaper for four weeks. It also required that a copy should be deposited in the office of the secretary of state. A more liberal, or, rather, less illiberal, law was passed on this subject in 1831. By this act, the exclusive right is extended to twenty-eight years, with a right of renewal for his life, if the author is living at the expiration of the first copyright. It dispenses with the publication of the clerk's certificate in a newspaper—a very useless provision; for, the work itself gives notice that the copyright is cured, a person who pirates it can have no pretence

for alleging ignorance of the fact. The act, also, though it requires that the author shall supply a copy for the office of the secretary of state, excuses him from the trouble of depositing it there, requiring him only to leave it in the office of the clerk of the district court. See *Copyright*.

LITERATURE, according to the English dictionaries, means *learning*. In general use, however, this word, in English, commonly signifies what in other countries would be called *elegant literature*, excluding works of abstract science, and mere erudition. The meaning of the word, in English, however, is vague. In German and French, the word means distinctly, the whole which has been written. Hence the phrase "literature of the middle ages," or, "medical literature," means the aggregate of works written during the middle ages, or on medicine, &c. *Literary* is applied to all those branches of reading which come within the scope of a general reader; the phrase "literary gentleman" corresponds pretty nearly to the French *homme de lettres*. *Literary gazette* is a journal which treats of works interesting to a general reader. In literary history, the word has a more extensive meaning. See *Literary History*.

LITHIA; the name applied by Arfwedson to an alkali discovered by him in analysing the petalite. The name was derived from the Greek *λίθος* (stony), in allusion to the existence of the earth in a stony mineral. Lithia has since been detected in spodumene, and several kinds of mica. The best process for procuring it is the following: One part of petalite or spodumene, in fine powder, is mixed intimately with two parts of fluor-spar, and the mixture is heated with three or four times its weight of sulphuric acid, as long as any acid vapours are disengaged. The silica of the mineral is attacked by hydrofluoric acid, and dissipated in the form of fluosilicic acid gas, while the alumina and lithia unite with sulphuric acid. After dissolving these salts in water, the solution is boiled with pure ammonia to precipitate the alumina; is filtered, evaporated to dryness, and then heated to redness, to expel the sulphate of ammonia. The residue is pure sulphate of lithia, which is dissolved in water, and decomposed by acetate of barytes; and the acetate of lithia, being heated to redness, is converted into the carbonate of lithia, and, finally, this is decomposed by lime or barytes, which affords pure lithia. Its colour is white; it is not deliquescent, but absorbs carbonic acid from the air; very soluble in water; acrid, caustic, and acts on colours like the other alkalies: heated with platina, it acts on the metal. It combines with the different acids, and forms salts with them, like potash and soda, though possessed of a higher neutralising power than these alkalies. Its phosphate and carbonate are sparingly soluble; its chloride is deliquescent and soluble in alcohol, and this solution burns with a red flame. All its salts give a red colour, when heated on a platinum wire before the blowpipe. The muriate and nitrate are deliquescent. The metallic base of lithia was evolved by Sir H. Davy, by galvanism; but it was too rapidly oxidized to be collected: the metal was, however, seen to be white like sodium, and burned with bright scintillations.

LITHIC ACID, in combination with potash, is obtained from human urinary calculi, by digesting them in caustic lixivium: the lithate of potash gives up the lithic acid, on being mingled with acetic acid. It has the form of white shining plates, which are denser than water; is without taste or smell, and dissolves in 1400 parts of boiling water. It reddens the infusion of litmus. The lithates are all tasteless, and very sparingly soluble in water. Lithic acid, by

repeated distillations, is resolved into ammonia, nitrogen, and prussic acid.

**LITHOCHROMICS**; the art of painting in oil upon stone, and of taking impressions on canvass. This process, which is designed to multiply the master-pieces of painting, was invented some years ago by Malapeau, in Paris, who received a patent for his invention, and has an establishment for lithochromic productions, which have been popular in Paris since 1823. This process is a substitute for the copying of portraits; it also served as a cheap means of ornamenting walls. This art, however, is still in its infancy. The lithochromic printings yet produced, are less valuable than the poorest copies. A similar, but much superior invention has been made by Senefelder, which he calls *mosaic impression*.

**LITHOGRAPHY** (from *λίθος*, stone, and *γραφειν*, to write).\* The art of printing from stone, was invented at Munich, between the years 1795 and 1798, by Alois Senefelder. Peter Senefelder, the father of the inventor, was an actor at the theatre royal in that city, and intending to bring up his son to the law, placed him at the university of Ingolstadt. The dramatic inclination of young Senefelder, however, displayed itself in private theatricals; and, in 1789, he composed and printed a little comedy, called '*Die Mädchenkennner*,' for which he obtained some applause and profit. This success, and the death of his father, by which he was placed in reduced circumstances, fixed his determination of quitting the university, and attaching himself to the theatres. For two years he seems to have experienced all the miseries of a life of green-room vicissitudes, and then to have taken up the no less uncertain profession of authorship.

As a play which he had written could not be got ready in time for the Easter book fair at Leipsic, his second publication produced but barely sufficient to pay for the printing, to accelerate which he had passed much time in the printing-office, an anxious, and, as it will appear, no inattentive spectator. "I thought it so easy," says Senefelder, in his work on Lithography, "that I wished for nothing more than to possess a small printing-press, and thus to be the composer, printer, and publisher of my own productions."

After a variety of experiments made with the view of carrying this wish into effect, in the course of which Senefelder was compelled to substitute materials less expensive, or to him more manageable, for those commonly used by printers, he accidentally invented an art which will hand his name down to posterity. Among the materials employed by him were polished blocks or slabs of Kellheim stone, and on these he endeavoured to etch his composition, in imitation of the manner of copperplate engravers, with very imperfect success.

"I had just succeeded (he himself says) in my little laboratory in polishing a stone-plate, which I had intended to cover with etching ground, in order to continue my exercises in writing backwards, when my mother entered the room, and desired me to write her a bill for the washer-woman, who was waiting for the linen. I happened not to have even the smallest slip of paper at hand, as my little stock of paper had been entirely exhausted by taking proof impressions from the stones; nor was there even a drop of ink in the inkstand. As the matter would not admit of delay, and we had nobody in the house to send for a supply of the deficient materials, I resolved to write the list with my ink prepared with wax, soap, and lamp-black, on the stone which I had just polished, and from which I could copy it at leisure. Sometime

after this, I was going to wipe this writing from the stone, when the idea all at once struck me to try what would be the effect of such a writing with my prepared ink, if I were to bite in the stone with aqua fortis; and whether, perhaps, it might not be possible to apply printing ink to it, in the same way as to wood engravings, and so take impressions from it."

The result of the subsequent experiments was the art of printing from stone, the principle of which I may be here necessary briefly to explain. Its foundation is the fact known to every one, that grease will readily adhere to grease, and be repelled by water.

The lines required to be printed are drawn on stone with a greasy composition formed of tallow, bees' wax, shell-lac, and common soap, in equal parts which will not unite with or be affected by water previously to printing, the surface of the stone is wetted, and it is, therefore, prevented by the moisture from receiving the printing ink when applied, except on those places covered with the greasy composition. A roller charged with printing ink (which is not hardly to be stated is greasy) being passed over the stone, the printing ink readily adheres to the greasy lines of the drawing, but does not adhere to the other parts of the surface which retain the water. The print is obtained by pressure, which removes the printing ink from the lines of the drawing, and between each impression the operation of wetting the stone with a sponge, and applying the roller charged with printing ink is repeated. Such is a brief outline of the process of lithographic printing, but for every other art, simple as the general principle appears, a knowledge of the numerous details necessary to make a skilful practitioner can only be acquired by experience, and must be gained by much execution.

Unable, from the want of pecuniary resources, to pursue his discovery, or obtain any advantages from it, Senefelder, tempted by a bounty of two hundred florins, determined to enlist as a private soldier with artillery, with the enthusiastic expectation that the small sum might ultimately enable him to bring his invention into practice, and secure to himself an honourable competency and reputation. The feeling of an ingenious mind under the circumstances of Senefelder must be interesting; but his situation, at this time, was one rather of romance than of ordinary life, and cannot be better told than in his own words, nor will any one who reads the plain and nearly narrative published by him, entertain a doubt of the uncoloured truth of the relation.

"I was quickly resolved, and on the third day after forming my resolution, I went to Ingolstadt with a party of recruits to join my regiment. It was not without some feelings of mortification and humbled pride that I entered this city, in which I had formerly led the independent life of a student, but the consciousness of my own dignity, and enthusiasm for my new invention, greatly contributed to restore my spirits. I slept in the barracks, where I was not a little disgusted by the prevailing filth and vulgar jargon of a corporal. The next morning I was to enlist, but to my great disappointment the commander of the regiment discovered that I was not a native of Bavaria; and, therefore, according to a recent order of the Elector, could not serve in the army without obtaining a special license. Thus my last hope failed me, and I left Ingolstadt in a state of moral bankruptcy on despair. As I passed the great bridge over the Danube, and looked at the majestic river to which I had been twice nearly drowned while bathing, I could not suppress the wish that I had not been discovered, as misfortune seemed to persecute me with the utmost rigour, and to deny me even the last prospect

\* For the historical portion of this article we are indebted to the "Foreign Review," No. VII.

of gaining an honest subsistence in the military career."

On Senefelder's return to Munich, chance threw in his way Mr Gleissner, a musician of the Elector's band, to whom he had formerly been known, and who was about to publish some music. Senefelder communicated to him his invention of printing from stone, and it was soon determined that by this new method Gleissner's music should be given to the world. The composing, writing on stone, and printing of twelve songs was accomplished in less than a fortnight, and one hundred and twenty copies taken at the expense of about thirty florins. In a short time the entire impression was sold for one hundred florins, thus leaving a profit of seventy florins, or rather more than two hundred per cent.

In addition to this prosperous commencement, count Töring having laid a copy of the work before the Elector Charles Theodore, Mr Gleissner received a present of one hundred florins, with the promise of an exclusive privilege for this method of printing. Two or three other publications, one of which was Cannabick's "Ode on the death of Mozart," respectively yielded some profit, and Senefelder saw his invention established with every appearance of successful results. But, amidst these bright prospects, his ardour seems to have been damped at the reception of a communication which he made to the Electoral Academy of Sciences, explanatory of his mode of printing from stone. In this he stated its peculiar advantages, and dwelt at some length on the cheapness of the means by which it was performed, and instanced his own printing-press which had not cost more than six florins. Von Vachieri, the vice-president, presented him with twelve florins, intimating that his "Memoir" had been very favourably received; and adding, that as the expenses of the press, according to his own statement, did not exceed it, he hoped that a double compensation would satisfy his expectations. "I, indeed," says Senefelder, expected a very different treatment from the guardians of science and art, whose duty it is to investigate the value of every new invention, and if approved to submit it to the notice of their government."

This was in 1796. As employment increased, Senefelder set himself to work to construct an improved press; but a defect, apparently of the most obvious kind, occasioned a variety of embarrassments. A clumsy manual operation was substituted for a press, and by this means Senefelder hoped to be able to fulfil the engagements which he and Mr Gleissner were under.

Mr Falter, a music-seller at Munich, employed Senefelder to write and superintend the printing from one an arrangement of Mozart's "Zauberflöte," at this effort was unfortunate.

It would be tedious to follow the various struggles of the ingenious Senefelder, or to enumerate his lithographic labours; so far, his personal history is that of the art, which having made certain advances, as of too much importance to continue long a secret. In 1799, when Senefelder received from the king of Bavaria an exclusive privilege to practise his new art for fifteen years, his two brothers were employed by him, as well as two apprentices; and on this act of notice, he no longer made a mystery of the process. 1800, a circumstantial description of it was lodged in the patent office in London, and, in 1803 with the government of Lower Austria.

Amongst the strangers, who from motives of curiosity visited Senefelder's establishment, was Mr André, an extensive music publisher; he admired the facility of lithographic printing, and his respect for the invention induced him to make Senefelder the offer of 2000 florins for an unreserved

communication of all the particulars of his art, and the establishment of a press at Offenbach. If André's views had been confined to his immediate trade, his anticipations of the value of lithography would probably have been realized, but feeling a confidence in the vast power of the art, his views became ambitious; he proposed obtaining patents for the exclusive exercise of it in Vienna, London, Paris, and Berlin, simultaneously: he came over to England on the speculation of its application to cotton printing, without much previous knowledge of either art; and to this point the attention of Senefelder was, in consequence, for a considerable time, almost exclusively devoted.

On the return of Mr André to Germany, he prevailed on Senefelder to visit London, for the purpose of superintending the formation of a lithographic establishment. After nearly a year's absence, Senefelder arrived at Offenbach, where he found his family involved in a fierce dispute with Mr André respecting their claim to the exclusive right of practising his invention, and this led to a separation between Senefelder and André. His next patron (if indeed the name of patron can be applied to a connexion avowedly formed on mercenary motives) was Mr Von Hartl, imperial court agent at Vienna; and he appears also to have entertained sanguine expectations from the application of lithography to cotton printing. During the next three or four years various partnerships were formed, and successively broken up, whenever it was discovered that immediate and extensive profits did not follow their formation.

But the art was no longer a secret, and in defiance of Senefelder's privilege, it was practised by several individuals and public establishments. "I rather suspect," says Senefelder, "that the opinion of my art having been long kept secret, arose from the circumstance that several of my former workmen or other persons who had by accident heard something of lithography, treated it as a great secret, in order to obtain greater consequence; some of them even went so far as to travel about and to sell their secrets and prescriptions to credulous persons, in some cases, for considerable sums."

In 1809 there were, besides Senefelder's, six lithographic printing-houses at Munich; and several amateurs and artists had presses erected for their own use. To trace further the gradual diffusion of lithography in Germany is unnecessary, and would be tedious; we, therefore, turn our attention to its introduction into Britain and France.

Senefelder, about the year 1802, as has been stated, joined Mr Philip H. André in London, where his art was announced, under the name Polyautography. A caveat had been entered in the patent office to secure, if necessary, the exclusive exercise of the invention in England; but we believe no patent for it was ever taken out, although the specimens published by André in 1803, bear the legend "By his majesty's royal letters patent." Senefelder complains of the seclusion in which Mr Philip André kept him, under the idea that he might divulge the process; but in justice to Mr André it must be mentioned, whatever his conduct towards Senefelder may have been, that he not only readily communicated the general principles of lithography to several artists in London, but admitted them freely into his printing room. This *fac simile* method of multiplying drawings from the hand of the original designer alarmed the engravers, who, on the supposition that their craft was in danger, exerted themselves to cause lithography to be received as a whimsical invention, of no real importance, and one which could never be brought to any degree of perfection. The artists also, at this period, after one or two careless trial sketches, and without due attention

to its capabilities, fell readily into the same opinion; ascribing as inherent defects of the invention what ought to have been attributed to their own incompetency; for it was unfair to expect that any of them, however eminent in their peculiar practice, should with a single effort obtain a perfect result. As a body, the British artists appear to have resigned lithography to its fate, with the feeling that it would never satisfy the expectations which its announcement had excited.

The first effort, therefore, to introduce the art into Britain by André completely failed, and he left the country. Lithography was next practised in London by two Germans, named Volweiller and Kergenrader; but they were equally unfortunate with André, and lithography would have been a second time driven out of Britain, had not the late Colonel Brown (assistant quartermaster-general) met with specimens, which convinced him that at least it was peculiarly well adapted for military and official purposes.

The quartermaster-general authorized the purchase for a hundred pounds of the secret (as it was then called) of stone printing, with the materials from Volweiller, who, with his partner, returned to Germany in 1807. Owing to Colonel Brown having misunderstood or forgotten part of the process, and perhaps also from the natural timidity attendant on a first essay in an occult art, the attempts made by him at printing were abortive; and the practice in Britain must have been abandoned, had not lieutenant Pawley accidentally discovered the man whom both André and Volweiller had employed to prepare the stones and assist in working the press. This person, whose name is Redman, had acquired a knowledge, or rather had picked up a smattering of the general process, and with his aid the experiments at the Horse Guards became tolerably successful. The first map (a sketch of Bantry bay) was produced in the beginning of the year 1808; but previously to the appointment of Sir Willoughby Gordon as quartermaster-general, in 1811, the art was only used as an auxiliary to the military depot. From that date, lithography became of importance in the hands of the British government; and on a representation to the secretary at war, it was applied to printing the circulars of his office. At the present time the quartermaster-general's department executes lithographic printing for the treasury, war, commander-in-chief's, adjutant-general's and army pay offices; the home department, military asylum, commissariat, army medical department, office for military boards, recruiting department, &c. Plans and maps to a very large number have also been drawn and printed occasionally for both houses of parliament, with several laborious surveys relating to the new lines of roads through England, for the general post office.

Lithography is now, even in the hands of an inferior printer, no longer an imperfect art, as the supposed impossibility of repairing an injury, or correcting a fault, after impressions have been taken, is obviated by an important discovery made by Mr Coindet, the head partner of the house of Engelmann, who, in 1827, opened a lithographic establishment in London. This gentleman, acting on some experiments made at Mulhausen, was enabled, after a great deal of difficulty, to give to artists the power of retouching their drawings, after they had been etched. Several British artists have employed this method of retouching with success, some, indeed, in changing the composition of their drawings; others in altering the effect.

In France lithography was first introduced about the year 1807, by M. André, who disposed of "the secret" to whoever was willing to purchase it, for such sums as he could obtain.

In 1810, the French government refused M. Man-

lich, keeper of the king of Bavaria's press, permission to form a lithographic establishment; and it was not until 1814 that the art seems to have obtained popular notice in France.

We shall now proceed to give a description of the materials employed.

The stone best adapted for this kind of printing, and that used for the finest work, is procured from quarries situated along the banks of the Danube, at Pappenheim in Bavaria. They are of a calcareous nature, and contain a little flint. The color is a grayish-yellow. The grain is very fine, as being nearly of the same hardness as marble, they take on a very fine polish. When wetted, they lose the property of retaining the water for a considerable time, on which depends their great use in lithography. Stones of an inferior description have been found at Chateauroux; they are not uniform in the grain, as are, moreover, in large blocks, which must be cut into thin plates, whereas the Bavarian stone is found in flat strata, uniform in thickness, and most ready for use. Stones fitted for printing have likewise been found at Corston, near Bath, and at Stony Stratford; but they also are inferior to the German. The thickness of the stone must now in proportion to its surface, varying from an inch and a half to two inches and a half, which thickness is quite sufficient for a stone of ten square feet. When good stones cannot be had, a substitute may be formed by a mixture of lime and sand, together with the caseous or cheesy part of oil, so that the compound when dry, may be about the hardness of marble.

A table is necessary, in order to lay the stone on, and keep it steady when it is grinding or polishing (operations which will afterwards be described); may be formed of stone, metal, or wood, but it is best to have the edges, and holes to permit the escape of water.

A drawing table is also required, of such a size as to contain the stone, and having pieces of wood at each end, in order to support a roller, or flat bar, that lies across the table, and above the stone, so that the draughtsman's hand may not come into contact with the surface of the stone.

The ink table is usually made in the form of a box, on the upper surface of which the ink is spread and taken off by a roller covered with soft leather, and made elastic by stuffing. The interior of the box is occupied by various small articles required in the process of printing.

A mould for fashioning chalk pencils is used. It is commonly formed of brass, and contains about twenty holes, into which the composition is poured while in a soft state. The nature of the chalk composition, as also of the ink, will be afterwards described.

Steel pens are used in preference to quills, because they make much finer work, although they cannot be handled with so much dexterity. They are made of watch springs, or steel ribands made for the purpose. The pen is first formed by cutting the steel into a pair of scissors, and then brought to the proper degree of fineness by means of a hone. This done the pen is fashioned into a semicylindrical form by beating it with a small hammer, and in this state is fixed on a handle by means of a bit of quill.

Various other articles are used, such as rubbing or scratching knives, points, graters or barres, flat pencils, brushes made of badger's hair, &c.

The most improved form of the lithographic printing press is represented in the annexed wood engraving. The construction is much more simple than the presses usually described in articles on this subject; the action of the press is at least equal to them, and it is far less liable to go wrong. The stone of the

press A A A A, consists of four stout legs, firmly fixed to the floor, and spread out like the feet of a desk stool, as is seen in the figure, in order to insure stability. The upper ends of these feet are connected by four strong bars forming the support of the press. Two uprights rise from this frame, one on each side of the press; the one next the eye being shown at B. Each of these uprights has a smooth cylindrical rod, which serves as a guide to the platten or scraper box C, so that it may move easily up or down in a direction perpendicular to the table of the press, which is shown at D. This table moves on rails, in a manner similar to the table in the press of earl Stanhope (See *Printing Press* in this work), and on the table the stone is put from which the impression is to be taken. The platten, or scraper box, is pressed down by means of the lever E, which is brought down in the direction of the table rail, and its lower extremity being formed like a wiper, or having a curved shape, drives down a spindle in the centre of the platten, and presses it on to the table. There is a spring fastened to the middle of the spindle, and fixed to the side uprights, which causes the scraper box to rise so soon as the lever E is allowed to rise to the position represented in the engraving. There is a roller crossing the press, and on a level with the top of the frame, which is turned by the handle G, and so situated that when turned, it causes the table to move under the scraper box. F represents the tympan, a rectangular iron frame, moveable at a joint at the bottom, which frame is covered with parchment similar to the tympan in the press for type setting. The scraper is a wedge-formed plate of steel, fixed into the bottom of the platten with its edge downmost, and nicely adjusted by screws so that it may lie parallel with the face of the stone lying on the table of the press. The operation of the press is simply this: the stone being prepared with the drawing in a manner that will afterwards be described, is laid on the table, the paper is laid over and the tympan brought down. The table is then moved forward to the scraper, the long lever is brought down, and the handle G is turned so as to draw the stone under the scraper, which is kept pressing upon the tympan; the pressure is then taken off, and the stone moved back to its former position by turning the handle G.

The manner of preparing the stone depends upon the kind of work to be executed. To prepare them for printing chalk drawings, two stones of the required dimensions are selected, one of which is placed upon the table formerly described, with a little finely powdered quarts or hard sand (silver sand is the best that can be procured in this country). A little water is then put on the stone, and the other stone, being placed upon it, they are ground by giving the

upper stone small circular sweeps in various directions. Sand and water being constantly added, the grinding is continued until the surfaces of the stones are quite level. The sand must be passed through a sieve, in order to obtain it of equal grain. When ground, the stone should be carefully washed. When dry, the stone ought to have a uniform colour, and be perfectly free of scratches. M. Jobard, a lithographer, in Paris, has lately discovered an improved method of grinding, which consists in using a spoonful of starch along with the sand. The greatest care is necessary in cleaning the stone of both starch and sand, by means of a brush and water.

When the stone is to be prepared for ink drawings or writings, it must be polished. The grinding process, already described, is first pursued, and the polish is then given in the following manner. The circular motion is continued, and water but no more sand is added, until no grains appear, the polishing being given by the sort of paste formed by the water and the attenuated sand. The stone is now washed, and the same process is continued with powdered pumice stone. A fine polish is thus obtained; but the finishing is effected by polishing the stone with a large piece of pumice stone until the polish is equal to that commonly given to marble, i. e., until objects are seen reflected from the surface when the eye is placed near it.

When a drawing or stone has been used, it must be carefully taken out by rubbing two stones together with water, and that immediately after coming from the press. Ink drawings are much more difficult to efface than chalk ones. When all traces are effaced, the stone must be washed with dilute nitric acid, the acid being five per cent. the bulk of the water.

Ink for this kind of drawing should be insoluble in water, flow easily from the pen, not liable to spread on the paper or stone, to which last it should adhere firmly, have great solidity on being treated with the acid solution, and, lastly, a good body of colour. An ink having these properties is formed by a composition, the parts being taken by weight:

Dried tallow soap, . . . . .	30 parts.
Mastic in drops, . . . . .	30
Subcarbonate of potash, . . . . .	30
Chinese or table varnish, . . . . .	150
Lamp black, . . . . .	12

The tallow being well dried, the whole of the materials are put into a clean copper vessel, which is placed on a brisk fire. Keep stirring until the melting and mixing is completed, when they are to be poured into a mould of metal that has been heated to a considerable degree. The metal is heated so as to prevent the composition from cooling too rapidly, in order that it may the more easily be cut into regular strips. Such is the mode of preparing the ink for the stone. When the drawing or writing is to be done on paper, and from thence transferred to the stone, ink of a tougher nature is required, which may be composed as follows:—

Dry soap, . . . . .	100 parts.
White wax, without tallow, . . . . .	100
Sheep's fat, . . . . .	30
Gum lac, . . . . .	50
Mastic, . . . . .	50
Lamp black, . . . . .	30

Transfer or autograph paper is prepared thus: take smooth common-sized paper and lay a coat of

\* An inferior kind of ink is given in some works, consisting of equal parts of candle tallow, virgin wax, shell lac, common soap, and one twentieth part of the whole weight of lamp black.

starch over it with a fine brush, or camel's hair pencil. Parchment glue is preferable to starch. A superior kind of paper is made by taking thick unsized paper, and covering it with a thick solution of the following ingredients:—

Flour starch, . . . . .	120 parts.
Gum Arabic, . . . . .	40
Alum, . . . . .	20

The paper may be tinted by adding a small quantity of gamboge or Avignon seed. The composition must be laid on while hot, and the paper must be afterwards smoothed by being passed through the press. The lithographers in Paris employ rice paper for transferring sketches: the paper being, of course, covered by a thin coating of the starch composition.

Much of the beauty of chalk prints will depend upon the good quality of the chalk pencils or crayons. The following composition has been found to answer the purpose admirably:—

Dried tallow soap, . . . . .	150 parts.
White wax, . . . . .	150
Lamp black, . . . . .	25

The first two of these ingredients are mixed and melted in a copper vessel over a brisk fire; they are constantly stirred, the lamp black being added by little and little. The compound, while hot, is poured into the brass crayon mould, of which we have already spoken, the mould having been previously oiled to prevent the crayons from adhering.

The lithographic printing ink, is prepared in a similar manner to the ink employed by the letterpress printers. A quantity of linseed oil is boiled in a copper or brass vessel, until it burns when set fire to by a lighted paper, being kept burning till it is reduced in volume, by losing from one fourth to one half of its original bulk. The oil requires to be stronger for working crayon, than for working lithographic ink drawings. Regarding the thickness of the ink, experience alone can be the guide.

The lamp black used, should be that produced by the burning of rosin, when the ink is intended to be black. If the ink is intended to be blue, then Prussian blue or indigo is used, if red, vermilion and other colouring matters may be used, some of which must be mixed with oil of turpentine before they combine with the boiled oil.

There is a kind of ink used for preserving the drawing or writing upon the stone when the working is to be suspended for eight or ten days—it is called *preserving ink*. An excellent preserving ink is composed of,

Boiled oil, very thick . . . . .	2 parts
Sheep's fat . . . . .	4
White wax . . . . .	1
Oil of turpentine . . . . .	1
Lamp black . . . . .	4

The first three ingredients are brought to boil in a vessel over the fire, the turpentine is then added, and the lamp black by little and little, the mixture being constantly stirred. A table and roller must be kept for this ink alone.

When the paper to be used in printing is sized, it must be damped the night before use, in the same manner as is done by the letterpress printers, one sheet is passed through water and laid upon a table, ten or twelve dry sheets are laid above it, another wet sheet is laid above these, then dry ones, &c., the whole being pressed down by a board, and weights for two or three hours. But it is better that the paper should contain little or no size, in which case it does not require to be damped. The greatest care should be taken not to use paper made from rags that have been bleached with chloride of lime. By the use of such paper, the drawing will be inevita-

bly spoiled. Chinese paper, which is impregnated with alum, has a like effect.

In order to place a chalk drawing on the stone, the outline may be traced upon it with a hard wax pencil, or what is still better with red chalk, using care to lean very lightly. A still better method is to trace the outline with red chalk on a piece of paper: the stone is rubbed with a little turpentine, the paper laid on it wetted a little, and covered with a second sheet; the tympan is brought down upon it, and it is passed twice or thrice through the press, and the outline is transferred from the paper to the stone. Another method is to place a bit of red paper on the stone, the paper having been previously rubbed with red lead. On this the drawing is laid and the outline traced with a steel point. In this the outline and forming the shadows, the artist proceeds with his crayon in the same way as he would on paper. There is, however, much greater difficulty in keeping a point in the lithographic drawing, and considerable practice is necessary to attain a sufficient freedom of hand. The proper depth of stroke must be given at first, as it is not easy to deepen it by retouching. While putting in the light tint, the red must be fixed into a light reed, the metal portions being too heavy, and it is very difficult to lay a finer tint off well in the impression. A wedge shape is better than the point for the crayon, being less liable to break; when pieces do break off, they must be carefully brushed away. As the hand softens by the warmth of the hand, several pieces must be had in readiness to be used in succession.

In drawing with ink, the fine steel pen is used. The ink which has been cut into sticks, is now placed in a cup that has been previously warmed, and is poured upon it, and it is melted to such a degree of fluidity as will enable it to flow easily from the pen, but the dilution must not be carried further, as the lines laid on by the pen must be sound. The way of varying the depth of shade or tint, is by regulating the lines of different degrees of thickness, or by regulating their distance from one another.

In drawing on the stone, either with crayon or ink, the greatest attention must be paid to keep the stone clean; it must not be touched by the draughtsman's hand, nor should he even breathe upon it.

The next mode we shall notice, of procuring the writing of figures to be printed upon the stone, is by the transfer paper we formerly noticed. The paper being prepared as was stated with the standard composition, is commonly rubbed over with a soft powdered gum sandarac, after which the writing or drawing is executed with an ink of greater thickness than that used in writing upon the stone. When the transfer paper has been prepared, the stone is heated to a temperature of somewhat above 100° and laid on the table of the press. The paper is damped, and ere the stone is cold, it is laid on it, and passed several times through the press, by which means the writing is transferred.

The drawing being by any of these means put upon the stone, it is placed obliquely over a tank containing a weak solution of nitric acid poured upon it. The stone is reverted, that is, the under edge is now placed uppermost and the dilute acid is again poured upon it. From the nature of the stone, the nitric acid will cause it to effervesce: the strength of the solution should in general be about one part of acid to one hundred of water. The stone is now washed with rain water, after which gum water is poured upon it. The roller well charged with printing ink, is now passed over it in various directions until the drawing is completely inked, after which the stone is laid over with a solution of gum arabic of about the consistency of oil. Great nicety is required in this re-

cess, which is called etching: the strength of the solution will depend upon the nature of the stone, as likewise on the nature of the drawing. A strong etching liquor destroys the finer tints, and blackens the deeper shades: the strength of the acid solution must also diminish with the softness of the stone.

Wood cut engravings can be very well imitated in lithography, by covering the stone with ink, and taking out the light part by means of a steel point, the finer lines being put in with a hair pencil. When the drawing is finished, the stone is treated with the acidulated water as described above.

Copperplate prints may be very well imitated by engravings on stone. Take a well polished stone, and treat it with a solution of nitric acid, so that slight effervescence ensues. Wash the stone, and then cover it with a mixture of gum arabic and honey, and then spread over it a little lamp black when half dry; when dry, etch as in copperplate engravings, taking care not to make the lines very deep, fill in the hollow parts with linseed oil, which after a little must be taken out by pressing a blotting paper on it. The lines are then to be filled with a mixture of linseed oil and tallow in equal quantities, with a little lamp black. In two or three hours the stone is washed clean, and is then ready for use.

Engravings upon copper may be taken from the plate upon transfer paper, and then taken from it immediately upon the stone.

When the drawing or writing is placed upon the stone, it is prepared for printing. The stone is placed on the table of the press, and a proper sized scraper is placed in the scraper box, being adjusted with nicety by screws to touch the surface of the stone. The stone is gently washed with rain water, and ink taken upon the roller from off the ink table, and distributed upon the stone, in the same manner as in letterpress printing. The drawing receives the ink with difficulty at first, and two or three of the first proofs are commonly bad. The stone should be kept just wet enough to prevent the ink from going any place but the drawing, and a very little gum allowed to remain on the stone during the whole process. Should the ink go on any part where it ought not, it must be taken out by the application of strong acid. There are many particulars regarding press work, especially the tempering of the ink, which need not be specified here, as they can only be learned by practice.

When during the process of printing any error is found, and erasure becomes necessary, the following solution must be employed: dissolve two parts of potash, in 126 parts of pure water. The ink must remain a few minutes on the stone before being washed off, when the drawing will be effaced. The method is to wash with oil of turpentine, then come over it with vinegar of the ordinary strength.

LITHOTOMY is the name given to the operation for extracting the stone from the bladder. See LITHOTOMY.

LITHOTRITY; a surgical operation, by which the stone in the bladder is crushed by an instrument used and first applied by doctor Civiale, of Paris, 1786. He has written on the subject.

LITHUANIA (in the language of the country, *Lithuania*; in German, *Lithauen*); an extensive country formerly an independent grand duchy, containing 60,000 square miles, but in 1569, united to Poland. Since the dismemberment of that kingdom in 1793, 1793, and 1795, the greater portion of it was united to Russia, and forms the government of Mohilew, Witepsk, Minsk, Wilna and so. The climate is temperate and healthy, the face of the country nearly a level, inter-

rupted only by a few insignificant hills. The soil is in some parts sandy; in others marshy, or covered with woods; but, wherever it is cultivated, very productive. The principal rivers are the Duna, or Dwina, the Dnieper, the Niemen, the Prapiec and Bug. There are also many lakes and morasses. Lithuania raises considerable numbers of cattle, and produces abundance of corn, flax, hemp, wood, honey, and wax. The mineral kingdom yields iron and turf. The forests are full of game; among the wild animals are the urus, lynx, elk, beaver, &c. Corn, wax, honey, wolf and bear skins, leather, wool, and small but good horses, are exported. The manufactures are iron, glass, leather, and there are numerous distilleries. The Lithuanians, who are of the Lettish origin (see *Livonia*), were in the eleventh century tributary to Russia. They made themselves independent when Russia was divided by the troubles under the successors of Wladimir, and soon became formidable to their neighbours. Ringold, in 1235, bore the title of grand duke, and, under his successors, the whole of Russian Lithuania was separated from Russia. Gedemin conquered Kiev; Wladislaus Yagello was baptized in 1386, and, by his marriage with the Polish queen Hedwig, united Lithuania and the conquered Russian provinces with Poland. A portion of Lithuania, 6675 square miles, with nearly 400,000 inhabitants, now forms part of Gumbinnen, in the province of East Prussia, and is fertile and well cultivated. See *Russia*, and *Poland*.

LITMUS; a blue paste or pigment obtained from the lichen *parellus*. It is brought from Holland at a cheap rate, but is not much used in painting, for the least acid reddens it; but the colour is again restored by the application of an alkali. On this account, it is a very valuable test to the chemist for detecting the presence both of an acid and alkali. It is employed also for staining marble, and by silk dyers for giving a gloss to more permanent colours. Considerable quantities of the lichen are collected in the northern parts of Great Britain.

LITRE. See *France*, division *Decimal Measure*.

LITTER; a sort of vehicular bed; a couch or chair wherein the Roman patricians were borne by their servants, particularly on solemn public occasions, such as triumphal pomps or religious ceremonies. These litters were mostly provided with an awning or canopy, to preserve their occupiers at once from the heat of the sun and from the general gaze.

LITTLETON, or LYTTLETON, THOMAS, a celebrated English judge and law authority, born at the beginning of the fifteenth century, at Frankley, having been educated at one of the universities, was removed to the Inner Temple, where he studied the law, and became very eminent in his profession. In 1455, he went the northern circuit as judge of assize, and was continued in the same post by Edward IV., who also, in 1466, appointed him one of the judges of the common pleas. In 1475, he was created a knight of the Bath, and continued to enjoy the esteem of his sovereign and the nation until his death, at an advanced age, in 1481. The memory of judge Littleton is preserved by his work on Tenures, which has passed through a very great number of editions, those from 1539 to 1639, alone amounting to twenty-four. This work is esteemed the principal authority for the law of real property in England, while the commentary of Sir E. Coke is the repository of his learning on the subjects treated.

LITTORALE; an Italian word signifying the sea coast, applied particularly to the Hungarian province on the coast of the Adriatic, comprising the three towns Fiume, Buccari and Porte-Re, with

their territories, on the northern coast of Dalmatia. It formerly belonged to the military district of Croatia. The emperor Joseph II. annexed it to Hungary in 1776, and gave it a civil government for the encouragement of Hungarian commerce. The district had, in 1787, 19,928 inhabitants upon 140 square miles. From 1809 to 1814, it formed part of the Illyrian provinces of France. In 1814, it was restored to the Austrian empire, and, in 1822, was reunited with the provinces of the crown of Hungary. The seat of government is at Fiume. (q. v.)

**LITURGIA** (Greek, *λειτουργία*); the office of the *λειτουργοί*. These were persons in Athens, of considerable estates, who were ordered by their own tribe, or by the whole people, to perform some public duty, or supply the commonwealth with necessities at their own expense. This institution indicates the rudeness of an age in which political science had made but little progress. These *λειτουργοί* were of divers sorts, all elected out of 1200 of the richest citizens, who were appointed by the people to undertake, when required, all the burdensome and chargeable offices of the commonwealth, every tribe electing 120 out of their own body. These 1200 were divided into two parts, according to their wealth. Out of the wealthiest half, were appointed 300 of the richest citizens, who, upon all exigencies, were to furnish the commonwealth with necessary supplies of money, and, with the rest of the 1200, were to perform all extraordinary duties in turn. If any person, appointed to undergo one of the duties, could find another person more wealthy than himself, and free from all the duties, the informer was excused. This obnoxious institution was abolished on the proposition of Demosthenes. (See Wolf's *Prolegomena to Demosthenes*, Bockh's *Political Economy of Athens*, and Potter's *Grecian Antiquities*.) The word *λειτουργία* is the origin of the English word *liturgy* (q. v.), the sense having become contracted from public ministry, in general, to the ceremonies of religious worship.

**LITURGY** (Greek, *λειτουργία*, from *λειτουργία*, public, and *εργον*, work); a precomposed form of public worship. It is merely our intention here to mention some of the most important liturgies, without entering at all into the question of the primitive forms of worship in the Christian church. There are three liturgies used in the Greek church—those of Basil, of Chrysostom, and of the Presanctified. They are used in all the Greek churches subject to the patriarch of Constantinople; also in the countries originally converted by the Greeks, as Russia, Georgia, Mingrelia, and by the Melchite patriarchs of Alexandria, Antioch, and Jerusalem. (King, *Rites of the Greek Church*.) There are various liturgical books in use in the Roman Catholic church, the greater part of which are common to all the members in communion with the church, while others are only permitted to be used in particular places, or by particular monasteries. The Breviary contains the matins, lauds, &c., with the variations made therein according to the several days, canonical hours, and the like. There are various breviaries appropriated only to certain places; as the Ambrosian breviary used in Milan, the Gallican, by the church of France, and those of different monastic orders; but the Roman breviary is general. It consists of the services of matins, lauds, prime, third, sixth, nones, vespers, complines, or the *post-communion*, that is, of the seven hours, on account of the saying of David, "Seven times a day do I praise thee." It is recited in Latin. The Missal, or volume employed in celebrating mass, contains the calendar, the general rubrics, or rites of the mass, and, besides such parts as are invariably the same, the

*de tempore*, that is, the variable parts on Sundays and holydays that have proper masses: the *proprium sanctorum*, or the variable parts in the masses for the festivals of such saints as have proper masses; and *commune sanctorum*, or the variable parts on the feasts of those saints that have no proper mass. The canon of the mass was committed to writing about the middle of the fifth century. Gregory the Great made many additions to it. The Cereemonial contains the offices peculiar to the pope, treating of his election, consecration, benediction and coronation, the canonisation of saints, the creation of cardinals, the vestments of the pope and cardinals when celebrating the divine offices, &c. The Pontifical describes the functions of the bishops of the Roman church: such as the conferring ecclesiastical orders, consecrating of churches, manner of excommunicating, absolving, &c. The Ritual treats of those functions which are to be performed by simple priests, or the inferior clergy, both in the public service of the church, and in the exercise of private pastoral duties. The ancient Gallican liturgy is that which was in use among the Gauls before the time of Pagan and Charlemagne, who introduced the Roman mode of celebrating divine worship. The Spanish liturgy, more commonly called the *Mozarabic liturgy*, is derived from that of Rome. The Ambrosian liturgy, used in the cathedral at Milan, derives its name from St Ambrose, who made some changes in it. It does not differ from the Roman in doctrine, though it does in form. The whole of the Roman liturgy is in Latin: The Protestants all adopted their vernacular tongue in the celebration of divine service. In 1520, Luther drew up a liturgy, or form of prayer and administration of the sacraments, which, in many points, differed but little from the mass of the church of Rome (*Opera*, ii., 384). He did not, however, confine his followers to this form, and hence every country, in which Lutheranism prevails, has its own liturgy, agreeing with the others in the substance, but differing in many things of an indifferent nature. The prayers are read or chanted by the minister at the altar, and the subject of the discourse is, in most cases, limited to the epistle or gospel of the day. A new liturgy for the principal divine service on Sundays, holidays, and the celebration of the holy communion, was published at Berlin, in 1822. This was designed primarily for the use of the royal and cathedral church in Berlin, but has been generally adopted in Prussia. Calvin prepared no liturgy, but his followers in Geneva, Holland, France, and other places, drew up forms of prayer, of which the Genevese and the French are the most important. The Genevese liturgy contains the prayer with which divine service begins, a confession of sin, public prayers for every day in the week, and for some particular occasions, the Lord's prayer, decalogue, and creed, &c. A new liturgy of the French reformed church was compiled in 1826. The Kirk of Scotland, or the Scotch Presbyterian church, has no liturgy. The Directory for the public Worship of God contains directions for the assembling of the congregation, the manner of proceeding, &c. In 1534, the Book of Common Order, or Knox's Liturgy, was recommended to be used by those who were unable to pray without a set form. In England, before the reformation, the public service of the church was performed in Latin, and different liturgies were used in different parts of the kingdom. The most celebrated of these were the Breviary and Missal, compiled by the bishop of Salisbury about 1080. They consisted of prayers and other parts of very ancient origin, and others of the progress of later times. In 1536, by Henry VIII., the Bible, Paternoster, creed and decalogue, were

read in English. In 1547, Edward VI. commissioned Cranmer, Ridley, and eleven other divines, to draw up a liturgy in English. This was published in 1549, and again, with some changes, in 1551, whence it was called the *Second Prayer Book of Edward VI.* In the reign of James I., and, finally, at the restoration, it underwent new revisions. This was the last revision in which any alteration was made by authority. A liturgy of the New Church (Swedenborgians) signified by the New Jerusalem in the Revelation, was published by the Swedenborgian general conference in England, in 1828. The liturgy of the episcopal church in Scotland, is at present not very different from that of the church of England. The attempt of Charles I. (1637) to introduce into Scotland a book of common prayer, copied from the English, produced the solemn league and covenant. The Directory was afterwards adopted, but by no means strictly adhered to. In 1712, the English Book of Common Prayer was finally adopted, with some modifications. The Book of Common Prayer of the Protestant Episcopal church in the United States of America, was adopted in 1789, and, besides some minor deviations from the English, it omits the Athanasian creed, and, in the Apostles' creed, leaves the officiating minister the discretionary power of substituting, for the expression "he descended into hell," "he went into the place of departed spirits." It has adopted the oblation and invocation in the communion service, in which it approximates to the Scottish communion office, and has added six forms of prayer—for the visitation of prisoners; for thanksgiving for the fruits of the earth and other blessings; for morning and evening prayer in families; for the consecration of a church or chapel; and, lastly, a beautiful and impressive office of institution of ministers. See Kuecher's *Bibliotheca Liturgica*; Bingham's *Origines Ecclesiasticae*; Comber's *Scholastical History of Liturgies*.

**LIVADIA**; the ancient Hellas, or Middle Greece (see Greece); situated to the south of Janna, or Thessaly and north of Morea, bounded east by the Ægean, and west by the Ionian sea, 5800 square miles in extent, and containing 250,000 inhabitants, chiefly Greeks. The name is derived from the town of Livadia (or Lebadia; 2000 houses and 6000 inhabitants). The boundary between Livadia and Thessaly is formed by the mountain Ceta (on whose summit Hercules was buried), now called *Kumaila*. It is only accessible, at least for artillery, by a narrow pass between Ceta and the swamps on the Malian gulf (gulf of Zeitouni), or the famous pass of Thermopylae. In the war of the Greek revolution, several decisive battles were fought in this part of the country, the most bloody near the town of Zeitouni, the ancient Lamia, which lies to the north. From this pass, which is about six miles long, we enter, 1. Locria, the northerly part of Livadia; farther south, 2. Phocis, with the ancient Elatea, now Turkorio, watered by the river Cephissus, and intersected by mount Parnassus; and, still more southerly, 3. Boeotia; 4. Attica; and 5. Megaris; to the west, 6. Ætolia; and 7. Acarnania. The ancient names of places are now revived, and Middle Greece has been divided into East and West Hellas. (See *Greece, Revolution of Modern*.) The boundary of Greece, as settled by the protocol of February, 1830, runs north of Livadia, thus placing it within the kingdom of Greece. The character of the present inhabitants of these countries is as various as their descent and mode of life. The first inhabitants of the coast were chiefly of foreign, or, as the Greeks called it, barbarian descent. Their occupation was piracy. The mountaineers were robbers, constantly at war with their oppressors. Missolonghi, the only strong-

hold on the western coast, has been rendered celebrated by late events. To the north is the ancient Actium, or Asio. Trevesa, which, with Parga, and the coast of Epirus, was ceded to the Turks in 1800, and Arta, near the gulf of Arta, belong to Albania. In the southerly part of Locris lies Lepanto. In Boeotia is the town Livadia, formerly Lebadia, at the foot of mount Helicon, near which are the cave of Trophonius, and the fountains of Mnemosyne (memory) and Lethe (oblivion). Not far off are Leuctra and Platea, and the ruins of Thespiae, whose inhabitants were selected by Leonidas to die for their country, with the 300 Spartans. Tanagra, on the Æsopus, was the birth-place of the celebrated Corinna. Mount Cithæron divides Boeotia from Attica and from Megaris. See *Greece*.

**LIVE OAK.** See *Oak*.

**LIVER** (*jecur, hepar*); a large gland which occupies a considerable portion of the cavity of the belly, and which secretes the bile. It is a single organ, of an irregular shape, brownish-red colour, and, in general, is smaller in proportion as the individual is more healthy. It occupies the right *hypochondrium*, or space included by the false ribs, and a part of the epigastric region, and lies immediately under the diaphragm (midriff), above the stomach, the transverse colon, and right kidney; in front of the vertebral column, the *aorta* and the inferior *vena cava*, and behind the cartilaginous edge of the chest. The right false ribs are on its right, and the spleen on its left. The superior surface is convex, and the inferior is irregularly convex and concave, which has given risen to the division into the *right*, or *large* lobe, the *small*, or *inferior* lobe, and the *left* lobe. The right extremity of the liver is lower than the left, and is the most bulky part of the organ. The pressure of the surrounding organs, and certain folds of *peritoneum*, called its *ligaments*, which connect it with the diaphragm, retain the liver in its place, leaving it, at the same time, a considerable power of changing its relative position. The organization of the liver is very complicated. Besides its peculiar tissue, or *parenchyma*, the texture of which is unknown, it receives a larger number of vessels than any other gland. A peculiar venous system—that of the *vena portarum*—is distributed in it. To this must be added the ramifications of the hepatic artery and veins, the nerves, which are small, the lymphatic vessels, the excretory tubes, and a peculiar tissue, enclosed by a double membrane, a serous or peritoneal, and a cellular one. The excretory apparatus of the bile is composed of the hepatic duct, which, rising immediately from the liver, unites with the cystic duct, which terminates in the gall-bladder. The choledochic duct is formed by the union of the two preceding, and terminates in the *duodenum*. See *Gall-Bladder*, and *Bile*.

**LIVERPOOL**; a borough town of England, in Lancashire, and (next to London) the principal seaport in the British dominions: 204 miles from London; 36 from Manchester: lon. 2° 59' W., lat. 53° 25' N. It extends along the eastern bank of the Mersey, about three miles, and, at an average, about a mile inland. On the west side of it, and forming a remarkable feature in the town, lie the docks, which, with the wharfs, warehouses, &c., extend in an immense range along the bank of the river. On the other side, the town is prolonged into numerous suburbs, consisting of villas and country houses, the residence or retreat of its wealthy citizens.

The etymology of the name of Liverpool has been a matter of much conjecture. In the charter granted by king John, it is called *Lyr-pul*, meaning the harbour of the Mersey, derived from the Gaelic *Lyr*

the sea. Dr Enfield wishes to consider Leverpoole as the true orthography, and some suppose that it was thus derived from the family of Lever, of ancient standing in the county. Others would conclude that the Cormorant in its corporation seal, by the heralds called a Lever or Liver, gave its appellation; but the coat of arms is evidently a rebus from the name of the town. Others imagine that it is derived from the abundance of liverwort growing on the shore, but unluckily the liverworts are not marine plants, and the various species of *Ulva* thrown up by the sea are called laver, and therefore cannot have been the origin of the name, which it seems more safe to consider as a corruption from the original British *Lyrpwl*.

The early history of Liverpool is extremely meagre. Originally a fishing village, belonging to the parish of Walton, it is not mentioned in *Domesday Book*. It fell with the rest of the country between the Ribble and Mersey to the share of Roger of Pictou, who it is supposed built a castle here about the year 1076, on the site of what is now St George's church, which thus became the nucleus of a town. Liverpool is said to have received a charter of incorporation from Henry I. in 1129, and another from Henry II. soon after his conquest of Ireland; but both these charters are of very doubtful authenticity, if not confessedly spurious. The earliest really authentic document is a charter from king John, dated 1207, still preserved amongst the records of the town. So few incidents occur, in the lapse of five centuries, that the history of Liverpool may be summed up in relating that the Molineux family remained during this long period wardens of the castle; that in the thirteenth century a building was erected called the tower, at the bottom of Water street, as an outguard to keep watch for the safety of the castle, and that about the year 1360 it became vested in the Stanley family, by the marriage of Sir John Stanley with the heiress of Lathom. This building was occasionally the residence of the earls of Derby, and afterwards became a prison; its remains were replaced by warehouses in 1819. Between the Stanleys and the Molineux a feud so violent took place, in the reign of Henry VI., that government was obliged to interfere. At this period, and for many ages after, the knightly family of More, of Bank Hall, held large possessions and had a mansion in Liverpool. In the reign of Henry VIII. Leland describes the town as in a flourishing condition:—"Lyrpwl, alias Lyverpoole, a pavid towne, hath but a chapel, Walton a iiiij miles off, not far from the Se is parochie church, the king has a castelet there, and the earls of Darbe hath a stone house there. Irish marchauntes cum much thither as to a good haven; after that Mersey water cumming up to Runcorne in Cheshire, lieth among the commune people the name, and is Lyrpwl. At Lyrpwl is smaule custume payed that causith marchauntes to resorte. Good marchandis at Lyrpwl, and moch Yris yarn that Manchestre men do buy there." After this period the town seems to have fallen somewhat into decay, as in the year 1565 a town record states that the number of householders was only 138, and in a petition to queen Elizabeth, in 1571, it is styled her majesty's poor decayed town of Liverpoole; but at the latter end of this reign it appears to have somewhat recovered itself, as Camden's description of it is very similar to Leland's; but even at the period of the civil wars its relative inferiority to Bristol may be inferred from the former city being rated at £1000 for the illegal exaction of ship money, whilst Liverpool was required to furnish only £25. In the year 1644 the town was defended by colonel More against the army of

prince Rupert for three weeks, at the expense of which it was taken by storm, but the royal cause being soon after utterly ruined, at the battle of Marston Moor, Liverpool again fell into the hands of the parliament. In 1690 king William embarked at the place for Ireland, three days before the battle of the Boyne, which fixed the crown upon his head, and established the security of the protestant faith and the liberties of England. It was honoured, in 1688, by another royal visit, in the person of the prince of Wales, accompanied by the duke of Clarence, in present majesty. Liverpool escaped the worst of the rebellions in 1715 and 1745. Its history subsequent to the Restoration is the detail of its increasing commercial prosperity, one principle of which seems to be hinted at by Leland, in "the smaule custume payed." At the time of its erection into a separate parish, 1699, Liverpool appears to have contained a population of about 5000 persons; its great success and prosperity have been occasioned by the enterprise and skill of its inhabitants, by its local advantages, commanding the trade of Ireland and America, and by the enlarged wisdom of the corporation, in abolishing all exclusive laws, and encouraging by an entire freedom every species of industry and commercial talent.

The streets of Liverpool are mostly spacious, and some of them elegant, and the greater part of the town is lighted with coal gas. The older and more central parts of the town are in a state of improvement. The public buildings are elegant. The principal of these are the town hall, exchange, bankers' hall, exchange, lyceum, atheneum, Wellington museum, infirmary, workhouse, blue-coat school, dispensary, and asylum for the blind. There are at present about twenty churches belonging to the establishment, many of them of much architectural beauty, a greater number of chapels belonging to various denominations of dissenters; with four Roman Catholic chapels, a meeting-house for Quakers, and a Jews' synagogue. The charitable institutions are numerous and well conducted. About 1500 paupers are admitted annually into the infirmary. The blue-coat hospital maintains and educates about 200 boys and girls. The school for the blind is on a most extensive scale. A handsome and spacious theatre, and a circus, are open during great part of the year. At the royal Liverpool institution, public lectures are given; and attached to it is a philosophical apparatus and a museum of natural curiosities. A botanic garden was also established in 1801, at an expense of about £10,000. The lyceum and the atheneum consist each of a news-room and library. There are also the Union news-room, the music-hall, the Wellington rooms, opened in 1816, for balls, concerts, &c., the town hall, the exchange building, erected in 1803-8 for commercial purposes. The area enclosed by the fronts of these buildings and the town hall, is 197 feet by 178. In the centre of the area is erected a superb group of brown marble, supposed to be the largest in the kingdom, to commemorate the death of lord Nelson.

But the peculiar feature of Liverpool consists in its extensive docks, which have been both the cause and effect of its prosperity. The area of these excavations, including the various basins, quays, and dry docks, embraces a space little short of 500 acres. From the flatness of the shore, shipping must always have been liable to great inconveniences: the vessels were obliged to ride in a road rather than a harbour, exposed to sudden gales and hurricanes, which even at present cause much damage. The act of parliament for excavating the old dock was obtained in 1710; its surface was  $3\frac{1}{2}$  acres, but it is now filled up, and the new custom house built on its site.

The Salt House Dock was constructed by virtue of an act 10, George II.; it is the receptacle of ships in the Levant and Irish trade. In the third of George III., a much larger work, St George's Dock, was begun; this was followed by the King's Dock, opened in 1788, in which only the Virginia vessels laden with tobacco, and vessels from the East Indies, are allowed to discharge their cargoes. Soon after Queen's Dock, of still greater magnitude, was completed in 1796; it is frequented by timber ships from the Baltic and from America; Prince's Dock, 500 yards in length, was opened in 1821. This dock is enclosed by a wall, between which and the river is a spacious parade, commanding a delightful view of the opposite coast, and of the exhilarating scene presented by the continual bustle on the Mersey, constantly alive with steam vessels, which were first introduced in 1815. To the north of Prince's Dock, and communicating with it, is the new North Dock, and a large graving dock; also Clarence dock appropriated to steam vessels. To the south of the Queen's Dock is the Brunswick Dock, which is appropriated for vessels laden with timber. In addition to these works the duke of Bridgewater's estate has a small dock for the use of the flats navigating his canal; and there are various dry or graving docks, basins, and communicating branches: all these docks are gained from the Mersey, and are a splendid monument of human ingenuity and perseverance. The great advantages which they afford are obvious, when the ease and convenience of transacting business at Liverpool is compared with the hazard and delay of most other ports, not even excepting the metropolis.

The exports of Liverpool consist chiefly in the manufactured goods of England, such as earthenware, pottery, hardware, cotton, and woollen goods, much salt, and some coal; the imports in the produce of Ireland, such as butter, bacon, beef, pork, cattle, corn, linen, spirits, and wool; and the produce of Africa, the East Indies, and North and South America, viz. palm oil, red wood, ivory, tea, bark, rice, flour, hides, indigo, pimento, rice, rum, sugar, clove, tobacco, woods, and cotton wool: for which see article, Liverpool is the great emporium of the kingdom. In 1830, of 793,695 bales of cotton imported to England, 703,200 were carried into Liverpool. In 1824, the whole amount imported into Liverpool was 8,323 bales, of which 413,724 were from the United States of America. In 1824, the amount of exports of Liverpool was £20,000,000 sterling; number of vessels belonging to the port in 1829, 806, of 161,780 tons.

*Statement of the Amount of Dock Duties Received at the Port of Liverpool, in each Year, ending 24th June, from 1812 to 1835, inclusive.*

Year.	Number of Vessels.	Tonnage.	Amount of Dock Duties.		Duties on Goods.		Total Amount of Dock Duties.

See the article *Ireland* for a statement of the quantity and value of the agricultural produce imported into Liverpool from Ireland.

Liverpool has an extended system of canal navigation, which has grown up with its increasing trade, and by which it has a water communication with the North sea. The manufactures are chiefly those connected with shipping, or the consumption of the inhabitants. There are extensive iron and brass foundries, breweries, soap-works, and sugar-houses. In the vicinity are many wind-mills for grinding corn, which have a very striking appearance; also a large tide-mill, and another worked by steam. A great number of men are employed in building, repairing and fitting out vessels. Of the finer manufactures, the watch-movement and tool business is carried on extensively, and almost exclusively here; and in the neighbourhood there is a china manufactory, where beautiful specimens of porcelain are produced.

The Liverpool and Manchester rail road commences with a tunnel, twenty-two feet high, sixteen broad, 6750 long. The thickness from the roof to the surface of the ground, varies from five feet to seventy. About two thirds of it is cut through solid rock. The rail road is continued through the remaining distance of thirty miles, with embankments, viaducts and excavations. It is traversed by locomotive steam carriages, running at the rate of about twenty miles an hour. Two additional tunnels connected with the rail road, have been recently formed, under the town of Liverpool; one terminating at the docks and the other at the Haymarket. The quantity of merchandise conveyed between Liverpool and Manchester, has lately been estimated at 1500 tons a-day, the number of passengers at 1300.

The following is an account of the progressive increase of the population of Liverpool:—In 1700, 5000; in 1760, 26,000; in 1773, 34,407; in 1790, 56,000; in 1801, 77,653; in 1811, 94,376; in 1821, 118,972; in 1831, 165,175.

LIVERPOOL, CHARLES JENKINSON, earl of, was the eldest son of colonel Jenkinson, the youngest son of Sir Robert Jenkinson, the first baronet of the family. He was born in 1727, and educated at the Charter house, whence he removed to University college, Oxford, where he took the degree of M. A. in 1752. In 1761, he obtained a seat in parliament, and was made under-secretary of state. In 1766, he was

named a lord of the admiralty, from which board he subsequently removed to that of the treasury. In 1772 he was appointed vice-treasurer of Ireland, and was rewarded with the sinecure of the clerkship of the Pells, purchased back from Mr Fox. In 1778, he was made secretary at war, and, on the dissolution of the administration of lord North, joined that portion of it which supported Mr Pitt, under whose auspices he became president of the board of trade, which office he held in conjunction with the chancellorship of the duchy of Lancaster, given him in 1786. In the same year 1786, he was also elevated to the peerage, by the title of baron Hawkesbury, of Hawkesbury, in the county of Gloucester, and in 1796, he was created earl of Liverpool. He remained president of the board of trade, until 1801, and chancellor of the duchy of Lancaster until 1803. His death took place on the 7th December 1808, at which time he held the sinecures of collector of the customs inwards of the port of London, and clerk of the Pells in Ireland. The earl of Liverpool for a long time shared in all the obloquy attached to the confidential friends of the Bute administration, and, in a particular manner, was thought to enjoy the favour and confidence of George III., of whom it was usual to regard him as the secret adviser. The earl of Liverpool was the author of the following works:—A Discourse on the Establishment of a Constitutional Force in England (1756); a Discourse on the Conduct of Great Britain in Regard to Neutral Nations, during the present War (1758); a Collection of Treaties, from 1646 to 1673 (3 vols., 8vo, 1785); a Treatise on the Coins of the Realm, in a Letter to the King (1805).

LIVERPOOL, ROBERT BANKS JENKINSON, earl of; son of the preceding; born in 1770, and died in 1828; known in public life, from 1796 to 1808, as lord Hawkesbury; from 1812 to 1827, first lord of the treasury. He was educated at the Charter-house; on leaving which, he was entered of Christ church, Oxford. His father directed his reading and studies in political economy, and other branches of political science at this time; and, on leaving the university, Mr Jenkinson set out on his travels. He was in Paris at the outbreak of the French revolution, and, in 1791, took his seat in the house of commons, in which he distinguished himself as a debater and an efficient member of the house. In 1801, he was appointed secretary of state for foreign affairs, and two years later, was called to the house of peers as baron Hawkesbury. On the death of Pitt (1806), the premiership was offered him, but declined; and, after the short administration of Fox, his former office was conferred on him, in the Percival ministry. After the assassination of Mr Percival, lord Liverpool (as he had become, on the death of his father, in 1808) accepted (1812), though reluctantly, the post of premier. His administration was marked by great moderation and prudence at home, but the foreign department bore the different impress of lord Londonderry and Canning. Lord Liverpool lost popularity by the trial of the queen, which was closed, as is well known, by the abandonment of the bill of pains and penalties, on the part of the ministers. It was on this occasion, that earl Grey demanded of him "how he dared, upon such evidence, to bring forward a bill of degradation, the discussion of which had convulsed the country from one end to the other, and might have been fatal to her independent existence." A paralytic stroke, in the beginning of 1827, having rendered him incapable of attending to business, Mr Canning succeeded him in the premiership.

LIVERWORT. The plant so called is the *Hepatica triloba* of Pursh. Like many other supposed remedies, it has had a temporary reputation for the

cure of pulmonary consumption. It is a small little plant, flowering very early in spring, and is common to the United States and Europe. There are two varieties, one with obtuse, and the other with acute lobes to the leaves.

LIVERY (*livrée*). At the pleenary court of France, under the sovereigns of the second and third races, the king delivered to his servants, as also to those of the queen and the princes, particular clothes. These were called *livrées*, because they were delivered at the king's expense. The expense of these donations, together with that of the robes, the equipages, the presents for the nobles and to people, amounted to an immense sum. A prudent economy afterwards suppressed these pleenary robes, but the livery of the servants still remained. In London, by *livery* or *livery men*, are meant the freemen of the city who belong to the metropolitan companies, which embrace the various trades of the metropolis; they had the exclusive privilege of voting at the election of members of parliament and of the lord mayor. Out of this body, the common council, sheriffs, aldermen, and other officers for the government of the city, are elected.

LIVIA DRUSILLA; wife of the emperor Augustus, daughter of Livius Drusus Claudianus, who lost his life in the battle of Philippi, on the side of Brutus and Cassius. She was first married to Tiberius Claudius Nero, by whom she had two sons, Drusus and Tiberius. When she fled with her husband to Italy, before the triumvir Octavian, she narrowly escaped being made prisoner by him who afterwards became her husband. From that place, she went with her son to Antony, in Asia, and when her husband was reconciled to Augustus, returned to Rome. Here her personal and domestic charms made such an impression on the emperor that he repudiated his wife, Scribonia, to make a marry her, and, in the 715th year of Rome, was, though pregnant, from her husband. Livia knew how to use her power over the heart of Augustus, for the attainment of her ambitious purposes, and effected the adoption of one of her sons as successor to the throne. At her instigation, Julia, the only daughter of Augustus, was banished. Ancient writers, too, almost universally ascribe to her the death of the young Marcellus, of Lucius Caesar, and the banishment of Agrippa Posthumus. Augustus, being no longer any near relatives, yielded to her requests in favour of Tiberius. In the emperor's will, Livia was constituted the first heiress, and received into the Julian family, and honoured with the name of *Augusta*. She was also made chief priestess in the temple of the deified Augustus, and many coins were struck in her honour. But Tiberius proved himself very ungrateful to his mother, to whom he was indebted for every thing, and would not allow the senate to bestow upon her any further marks of respect. He did not, however, treat her in public with disrespect; but, when he left Rome in order to gratify his lusts in an unintermitted solitude, he fell into a violent dispute with her, did not visit her in her last sickness, would not see her body after her death, and forbade divine honours to be paid to her memory.

LIVINGSTON, BROCKHOLST, Judge of the supreme court of the United States, was the son of William Livingston, governor of New Jersey, and was born in the city of New York, November 25, 1757. He entered Princeton college, but, in 1776, left it for the field, and became one of the family of general Schuyler, commander of the northern army. He was afterwards attached to the staff of general Arnold, with the rank of major, and died in the honour of the conquest of Burgoyne. In

1779, he accompanied Mr Jay to the court of Spain, as his private secretary, and remained abroad about three years. On his return, he devoted himself to law, and was admitted to practice in April, 1783. His talents were happily adapted to the profession, and soon raised him into notice, and, ultimately to eminence. He was called to the bench of the supreme court of the state of New York, January 8, 1802, and, in November, 1806, was transferred to that of the supreme court of the United States, the duties of which station he discharged, with distinguished faithfulness and ability, until his death, which took place during the sittings of the court at Washington, March 18, 1823, in the sixty-sixth year of his age. He possessed a mind of uncommon acuteness and energy, and enjoyed the reputation of an accomplished scholar, and an able pleader and jurist, an upright judge, and a liberal patron of learning.

LIVINGSTON, ROBERT R., an eminent American politician, was born in the city of New York, November 27, 1746. He was educated at King's college, and graduated in 1765. He studied and practised law in that city with great success. Near the commencement of the American revolution, he lost the office of recorder, on account of his attachment to liberty, and was elected to the first general congress of the colonies; was one of the committee appointed to prepare the Declaration of Independence; in 1780, was appointed secretary of foreign affairs, and, throughout the war of the revolution, signalled himself by his zeal and efficiency in the revolutionary cause. (See his letters, in the *Diplomatic Correspondence of the Revolution*.) At the adoption of the constitution of New York, he was appointed chancellor of that state, which office he held until he went, in 1801, to France, as minister plenipotentiary, appointed by president Jefferson. He was received by Napoleon Bonaparte, then first consul, with marked respect and cordiality, and, during a residence of several years in the French capital, the chancellor appeared to be the favourite foreign envoy. He conducted, with the aid of Mr Monroe, the negotiation which ended in the cession of Louisiana to the United States, took leave of the first consul (1804), and made an extensive tour on the continent of Europe. On his return from Paris, as a private citizen, Napoleon, then emperor, presented to him a splendid snuff-box, with a miniature likeness of himself (Napoleon), painted by the celebrated Isabey. It was in Paris that he formed a friendship and close personal intimacy with Robert Fulton, whom he materially assisted with counsel and money, to mature his plans of steam navigation. (See *Fulton, and Steam-Boat*.) In 1805, Mr Livingston returned to the United States, and thenceforward employed himself in promoting the arts and agriculture. He introduced into the state of New York the use of gypsum and the Merino race of sheep. He was president of the New York academy of fine arts, of which he was a chief founder, and also of the society for the promotion of agriculture. He died March 26, 1813, with the reputation of an able statesman, a learned lawyer, and a most useful citizen.

LIVIUS, ANDRONICUS, the father of Roman poetry, by birth a Greek of Tarentum, first went to Rome at the commencement of the sixth century from the foundation of the city, as instructor to the children of Livius Salinator. He introduced upon the Roman stage, dramas after the Grecian model, and, besides several epic poems, wrote a translation of the *Odyssey*, in the old Saturnine verse. We have only a few fragments of his writings, which may be found in the *Comici Latini*, and in *Corpus Poëtarum*. See Fabricius, *Bib. Lat.* iv. 1; A. Livii, *Hist.* vii. 2.

LIVIUS, TITUS, born at Padua, in the year of Rome 695 (59 B. C.), came from the place of his birth to Rome, where he attracted the notice of Augustus, after whose death he returned to his native town, where he died A. D. 16. His history of Rome, to which he devoted twenty years, rendered him so celebrated, that a Spaniard is said to have gone from Cadix to Rome merely for the purpose of seeing him. Of the circumstances of his life we know little. He was called, by Augustus, the *Pompeian*, because he defended the character of Pompey, in his history; this, however, did not prevent his enjoying the patronage of the emperor till the time of his death. According to Suidas, Livy did not receive, during his lifetime, the applause which his history deserved, and it was not till after his death that full justice was rendered him. In the fifteenth century, his body was supposed to have been discovered at Padua, and a splendid monument was raised to his memory. His Roman history begins at the landing of Æneas in Italy, and comes down to the year of the city 744. His style is clear and intelligible, laboured without affectation, diffusive without tediousness, and argumentative without pedantry. His descriptions are singularly lively and picturesque, and there are few specimens of oratory superior to that of many of the speeches with which his narratives are interspersed. Yet he was accused (see *Quintilian*, viii. 1.) of provincialism (*"patavinitas"*). His whole work consisted of 140 or 142 books, of which we have remaining only the first ten, and those from the twenty-first to the forty-fifth, or the first, third and fourth decades, and half of the fifth. In the first ten books, the history extends to the year 460; the portion between the twenty-first and forty-fifth books contains the account of the second Punic war (A. U. C. 536), and the history of the city to the year 586. In 1772, Bruns, while engaged in collecting various readings, discovered, in a *codex rescriptus*, in the Vatican, a fragment of the ninety-first book; but it is not of much importance. It was printed at Rome, and reprinted at Leipsic, in 1773. The epitome of the whole work which has been preserved, has been ascribed, by some to Livy, by others, to Florus. Following this outline, and deriving his facts from other credible sources of Roman history, Freinsheim composed his Supplement to Livy. The best editions of Livy are those of Gronovius (Amsterdam, 1679, 3 vols.) of Drakenborch (Leyden, 1738—46, 4 vols.), and, among the later editions, those of Ernesti, Schafer, Ruperti, and Döring. The best English translation is that of George Baker (6 vols., 1797), which has been often reprinted.

LIVONIA. The Russian provinces upon the Baltic, viz. Livonia, Esthonia, Courland, and Semigallia, early belonged to the Russian states, as tributaries, while they retained their own institutions, and were never protected by the Russians from hostile inroads. During the period when the Russian empire was in a state of confusion, they became independent, but were again reduced to subjection by Peter the Great. Livonia was little known to the rest of Europe till 1158, when some merchants of Bremen, on their way to Wisby, in Gothland, in search of new sources of commerce, were thrown upon the coasts of Livonia. The country was afterwards frequently visited by the people of Bremen, who soon formed settlements there. An Augustine friar, Meinhard, with other Germans, emigrated thither about twenty-eight years after. He converted the inhabitants to Christianity, and was their first bishop. The third bishop after him, by name Albert, who advanced as far as the Dwina, first firmly established the foundations of the spiri-

tual authority. He built the city of Riga, in the year 1200, and made it the see of the bishopric. At the close of this century, the Danish king Canute VI., made himself master of these provinces, which were, however, given up by his successor, Wladimir III., for a sum of money, to the Teutonic knights, with whom the order of Brethren of the Sword, founded by Albert, in 1201, had been united, so that the dominion of the Teutonic order comprehended all the four provinces above mentioned. They were, however, too weak to hold them against the Russian czar, John II. Wasilowitch, who was bent upon reuniting them with the Russian empire, and the state was dissolved. Estonia then placed itself under the protection of Sweden; Livonia was united to Poland; and Courland, with Semigallia, became a duchy, under Polish protection, which the last grand master of the Teutonic order held as a Polish fief. From this time, Livonia became a source of discord between Russia, Sweden and Poland, for near a century, from 1561 to 1660. At the peace of Oliva, in 1660, this province was ceded to Sweden by Poland, and it was again united to the province of Estonia. By the peace of Nystadt, in 1721, both provinces were again united to the Russian empire. Livonia is bounded east by Ingria, south by Lithuania and Samogitia, west by the Baltic, and north by the gulf of Finland. It is productive in grass and grain, and consists of two provinces, Estonia and Livonia, of which the first lies upon the gulf of Finland, the last upon the borders of Courland and Poland. The Livonians, like the Lithuanians, are a branch of the Finns; and are, for the most part, in a state of servitude; but the grievous oppression, under which they were held by their tyrants, the nobility, has been much lightened by an imperial decree of 1804. Besides the original inhabitants, there are, in the country, many Russians, Germans, and Swedes. The greater part are Lutherans; but Calvinists, Catholics, and the Greek church, enjoy liberty of worship. In 1783, the country was newly organised, and Livonia became the government of Riga, and Estonia that of Revel. The name of Livonia was, however, restored by the emperor Paul, in 1797. It is, at present, divided into five circles. It comprises an area of 21,000 square miles, of level, marshy country, abounding with lakes. Riga, situated on the Duna, nine miles from the bay of the Baltic, is the chief place of commerce. The merchants there are mostly British. Population of the town about 36,000. The only other town of note is Dorpat, situated on the Embach, the seat of a university, established in 1802, and of a great annual fair. The government of Riga contains 980,000 inhabitants. See the *Essai sur l'Histoire de la Livonie*, by count de Bray (Dorpat, 1817, 3 vols.), and Granville's *Journey to St Petersburg*, (1828).

LIVRE; an ancient French coin. The word is derived from the Latin *libra*, a pound. It appears as early as 810 B. C. At first, the livre was divided into twenty *solidos*; afterwards into ten *sous*; in Italy, into twenty *solidi*; in Spain, into twenty *sueldos*, as the old German pound into twenty *schillinge*, and the English into twenty shillings. The livre was, at first, of high value. The revolution changed the name into *franc*. See *Franc*, and *Coin*.

LIVY. See *Livius*.

LIZARD. All reptiles having a naked body, four feet and a tail, are vulgarly known under the name of *lizards*. Linnæus himself only constituted two genera of this numerous class of animals—*draco* and *lacerta*; but more modern naturalists have greatly increased the number of genera. The following is the arrangement followed by Cuvier in the last edition of his *Règne animal* :—

## Second Order of REPTILIA, or SACCIVENS

FAMILY I. CROCODILIENS.	Serpentes, Croc. Crocodylus, Br. Sub-genera, 3.	FAMILY IV. GECKONES.
FAMILY II. LACERTINIENS.	Serpentes II. Iguanas proper Iguana, Cuv. Ophryotrogon, Br. Basiliscus, Br. Polychrus, Cuv. Euphryotrogon, Fitz. Ophryotrogon, Cuv. Anolis, Cuv.	FAMILY V. CHAMÆLEONES.
FAMILY III. IGUANIENS.	SECTION I. Anolis.	FAMILY VI. SCINCES.

Besides these, the salamanders, which belong to the fourth order, or *Batrachians*, are also generally named lizards. See *Alligator*, *Basilisk*, *Chamaeleon*, *Crocodile*, *Dragon*, *Gecko*, *Iguana*, *Monitor*, &c.

LIZARD, CARP; the most southern pumery of England, in the county of Cornwall.

LLAMA (*auachenia*, Illig.). This valuable animal, which supplies the place of the camel to the inhabitants of Southern America, is much more gentle and delicate than the Eastern "ship of the desert." Their slender and well formed legs bear a more equal proportion to the size and form of the body. Their necks are more habitually extended in an upright position, and are terminated by a small head. Their ears are long, pointed, and immovable; their eyes large, prominent, and brilliant, and the whole expression of their physiognomy conveys a degree of intelligence and vivacity far wanting in the camel. There has been much interference of opinion among naturalists as to the number of species. The first travellers in America spoke of the llama, the guanaco, the alpaca, and the vicugna, without giving such details as were requisite to identify them. Most of the early authors, including Linnæus, reduced them to two species, the llama or guanaco, used as a beast of burden, and the alpaca, paca, or vicugna, prized for its wool and flesh. Buffon was at first of the same opinion, but subsequently, admitted the vicugna as a third species. Molina also separated the guanaco, and added still the huacua or Chilean sheep, both of which were adopted by most subsequent compilers. De Cuvier, however, limits the number to three, rejecting the two last mentioned; whilst Lesson and Geoffroy only admits the llama and the vicugna, considering the alpaca as a variety of the first. The three inhabit the Cordilleras of the Andes, but are not common in Peru and Chile; they are more in Colombia and Paraguay. They congregate in large herds, which sometimes consist of upwards of a hundred individuals, and feed on a grass peculiar to the mountains, termed *yeco*. As long as they can procure green herbage, they are never known to drink. At the period of the arrival of the Spaniards in Peru, these animals were the only resources known to the inhabitants, by whom they were used as beasts of burden, and killed in vast numbers for their flesh and skins. Gregory de Bolivar asserts that, in his time, 4,000,000 were annually killed for food, and 300,000 used in the service of the natives of Peru. From the form of their feet, they are peculiarly fitted for mountainous countries, being, it is said, even safer than mules. They are also distinguished as a trifling expense, wanting, as is observed by Father Feuillée, "neither bit nor saddle; there is no need of oats to feed them; it is only necessary to send them in the evening, at the place where they are to rest for the night; they go ahead into the country to seek their own food, and, in the morning, return to have their baggage replaced, and continue their journey." They cannot carry more than from 100 to 150 pounds, at the rate of twelve or fifteen miles a day. Like the camel, they lie down to be milked.

and when they are wearied, no blows will compel them to proceed. In fact, one of their great faults is the capriciousness of their disposition. When provoked, they have no other mode of avenging themselves than by spitting, which faculty they possess in an extraordinary degree, being capable of ejecting their saliva to a distance of several yards. This is of a corroding quality, causing some degree of irritation and itching, if it falls on the naked skin. Besides their services as beasts of burden, the llamas afford various articles of so small utility to human life. The flesh is considered very wholesome and savoury, especially from the young animal. Their wool, though of a strong, disagreeable scent, is in great request, especially among the native Indians, who employ it in the manufacture of stuffs, ropes, bags, and hats. Their skins are of a very close texture, and were formerly employed by the Peruvians for soles of shoes, and are much prized by the Spaniards for harness. The female llama goes five or six months with young, and produces one at a birth. The growth of the young is very rapid; being capable of producing at three years of age, and beginning to decay at about twelve. The llama is four feet and a half high, and not more than six in length. He has a bunch on his breast, which constantly exudes a yellowish oily matter. His hair is long and soft; his colours, various shades of white, brown, &c. The tail is rather short, curved downwards. The hoofs are divided; or, rather, the toes are elongated forwards, and terminated by small horny appendages, surrounding the last phalanx only, rounded above, and on either side somewhat curved. There are several specimens of the llama in the different menageries in Europe, where they appear to thrive very well.

LLANEROS (from *llano*, plain); the inhabitants of the plains, or *Llanos* (q. v.). In this article we speak more particularly of those in Venezuela. The immense plains of Venezuela, which afford excellent pasture for all kinds of flocks and herds, are generally inhabited by converted Indians or descendants of Indians and whites, who are distinguished for activity, ferocity, ignorance and semi-barbarous habits, and are called *Llaneros*. From childhood they are accustomed to catch and mount wild horses, which roam by hundreds over the savannas. When at war, they are generally armed with a long lance, and often have neither swords nor pistols. Uniform is unknown among them; a few rags cover the upper part of their body; their pantaloons are broad and full, somewhat in the Mameluke style. They have blankets (*manuas*), as is the case with most Indians in habits of intercourse with whites; many of them have hammocks. They are brave in defending their plains. Their manner of fighting is much like that of the Osage; they never attack in regular files, but disperse themselves in every direction, rushing on, flying, repeatedly attacking and constantly harassing the enemy. *Paez*, who was born and bred among them, and is in manners, language and ferocity, a complete *Llanero*, commanded them during the war of Colombian independence, and is adored by them. They choose their own officers, and dismiss them at pleasure. They suffer no foreigners among them. As they have played a conspicuous part in the revolutions of Colombia, we subjoin the description of them by colonel Hippiusley, which is corroborated by general Ducoudray Holstein, in his *Mémoires of Simon Bolivar*. "Sedeno's cavalry (*Llaneros*)," says colonel Hippiusley, "were composed of sorts and sizes, some with saddles, very many of them without; some with bits, leather head-stalls and reins; others with rope lines, with a bit of the rope tied over the tongue of the horse as a bit; some old pistols hung over the saddle bow, either in-

cased in tiger-skin, or ox-hide holster-pipes, or hanging by a thong of hide, one on each side. As for the troopers themselves, they were from thirteen to forty-six years of age, of black, brown, sallow complexions, according to the castes of their parents. The adults wore coarse, large mustachios, and short hair, either woolly or black, according to their climate or descent. They had a ferocious, savage look. They were mounted on miserable, half-starved, jaded beasts, horses or mules; some without trowsers, small clothes, or any covering, except a bandage of blue cloth or cotton round their loins, the end of which, passing between their legs, was fastened to the girth, round the waist; others with trowsers, but without stockings, boots, or shoes, and a spur generally gracing the heel of one side; and some wearing a kind of sandal made of hide, with the hair side outward. In their left hand they hold their reins, and in their right a pole, from eight to ten feet in length, with an iron head, very sharp at the point and sides, and rather flat; in shape like our sergeants' halbert. A blanket of about a yard square, with a hole, or rather a slit, cut in the centre, through which the wearer thrusts his head, falls on each side of his shoulders, thus covering his body, and leaving his bare arms at perfect liberty to manage his horse, or mule, and lance. Sometimes an old musket, the barrel of which has been shortened twelve inches, forms his carbine, and a large sabre or hanger, or cut and thrust, or even a small sword, hangs by a leather thong to his side. A flat hat, a tiger skin or high cap, covers his head, with a white feather or a white rag stuck into it." This picture will remind the reader of some of the cavalry which Russia marched from her Asiatic dominions against France in the final struggle with Napoleon.

LLANOS; the name given in the northern part of South America, particularly in Colombia, to vast plains, almost entirely level, and interrupted only by detached elevations, called in Spanish, *mesas*. The superficial area of the *llanos* is estimated at 296,800 square miles; they extend from the coast of Caracas to Guiana, and from Merida to the mouth of the Orinoco and the Amazonas. A large portion of them is sandy and without much vegetation, except on the banks of the rivers and during inundations: some fan-palms are found. When the inundations occur, the beasts take refuge upon the *mesas*. The *llanos* have been supposed by some to have formerly been the bottom of the sea. They are distinguished into the (a.) *Llano of Colombia*, extending from the mountains of Caracas to the mouth of the Orinoco, and to the mountains of St Fé, and containing several *mesas* (de Amana, de Guanipa, de Paja, fifty to sixty-five feet in height), which, in the rainy season, are covered with rich verdure, and inhabited by herds and flocks of all descriptions.—(b.) *Llano de Casanare*; a continuation of the former, between the Orinoco, Meta and Sinaruca.—(c.) *Llano de S. Juan*; very fertile, woody, often so thickly overgrown, that it can only be penetrated by means of the numerous rivers; lies on the southern bank of the Meta, reaching to the Amazonas, and was discovered in 1541, by Gonzalo Ximenes Quesada.—(d.) *Llano of the Amazonas, or the Marañon*; on both sides of the river, extending from the Andes to the mouth of the Marañon, over 2100 miles; it is also wooded, and rich in grass, entirely without stones, and inhabited by many species of animals. The inhabitants of these plains are called *Llaneros* (q. v.). Farther to the south, such plains are called *pampas* (q. v.).

LLORENTE, DON JUAN ANTONIO, author of the first history of the Spanish inquisition, drawn from its own records, was born in 1756, near Calahorra, in Arragon. He received his education at Tarra-

gona, entered the clerical order in 1776, got a benefice at Calahorra, and, in 1779, by means of a dispensation (as he was hardly twenty-three years old), was consecrated a priest. This, however, did not prevent him from pursuing the study of the canon law, while he devoted his leisure to the muses. At Madrid, he was attracted by the theatre, and composed a sort of melo-drama, the *Recruit of Galicia*. A tragedy, entitled *Eric, the King of the Goths*, was not represented, as it contained allusions to existing difficulties at the court of Madrid. In 1789, he was made chief secretary to the inquisition. Here he had an opportunity to learn from the archives of the tribunal the history of its shameful and barbarous proceedings. In 1791, he was sent back to his parish, on suspicion of being attached to the principles of the French revolution, and in spite of the protection of the minister Florida Blanca, who was an enlightened statesman. Here he occupied himself actively in the support of emigrant French priests; and many of these unfortunate men were indebted to him alone for their subsistence. The manuscript of a history of the emigration of the French priesthood, founded upon the knowledge obtained from these acquaintances, and written in 1793, was lost by the fault of the censors of the press. In the mean time, don Manuel Abad la Sierra, an enlightened man, was made grand inquisitor, who, intending to reform the administration of this tribunal, employed Llorente to prepare a plan for the purpose. But, before it was completed, the removal of Abad la Sierra was obtained by his enemies. Some time after, the design was taken up again at Madrid, and Llorente repaired thither to submit the plan which he had prepared in conjunction with the bishop of Calahorra. Jovellanos (q. v.), minister of justice, supported them. It was proposed to make the proceedings of the tribunal of the inquisition public. All depended upon their obtaining the assistance of the prince of peace, the favourite of the queen. But Jovellanos was suddenly removed from office, and the inquisition remained as it was.\* (See *Inquisition*.) Llorente soon felt its arm himself. His correspondence was seized; the most innocent expressions were misinterpreted; he was sentenced to a month's confinement in a monastery, and to pay a fine of fifty ducats, and was removed from the appointments which he held in the Holy Office. He lived in disgrace till 1805, when his reputation caused him to be called to Madrid to investigate some dark points of history. He was then appointed a canon of the cathedral of Toledo in 1806, and, in 1807, after he had proved himself of noble descent, he was made a knight of the order of don Carlos. In the next year, when Napoleon undertook to regulate the affairs of Spain, Llorente repaired to Bayonne, at Murat's request, and took part in organising the new institutions of his country, which, however, could not take permanent root, as the clergy saw in them the destruction of their authority. When Joseph Bonaparte entered Madrid, in 1809, he charged Llorente to take possession of the papers of the inquisition, and of the buildings and archives which were under the superintendence of the general commandant of the place. In 1812, Llorente published an historical

memoir on the inquisition, with the view of freeing the Spanish nation from the charge of having ever been attached to this institution, and to the *auto de fé*. Llorente was almoner of king Joseph, who made him, successively, counsellor of state, commander of the royal order of Spain, commissioner-general of the *Cruzada*. He followed Joseph to Paris after the disastrous campaign of the French in Russia, and in 1813 had the intention of accompanying him to the United States; but, remaining to take leave of his family, he was induced to give up the plan. In 1817, he published his history of the inquisition in Spain, a French—a work which was soon translated into most European languages, and which has become an historical source. An abridgement has been published by Leonard Gallois. When the old authorities were restored, he was obliged to flee. Banished from his country, deprived of his property and of his library, Llorente lived in France, after the downfall of the French party in Spain, in indigence. But the hatred of the illiberal party arose, at last, to such a height, that the university of Paris forbade him from teaching the Spanish language in the boarding schools, which had been his only means of support. The rage of his enemies was raised to the highest pitch by the publication of his *Portraits posthumes des Papes*, and the old man was ordered, in the middle of the winter of 1822, to leave Paris in three days, and France in the shortest possible time. He was not allowed to rest one day, and died exhausted, a victim to the persecutions of the nineteenth century, a few days after his arrival in Madrid (Feb. 5, 1823). During his residence in France, he published his *Mémoires pour servir à l'Histoire de la Révolution d'Espagne, avec des Pièces justificatives*, under the name of R. Nello (an anagram of Llorente), in three volumes (Paris, 1815)—a work of value, as illustrative of the events of 1808, in Spain. He also wrote a biographical account of himself (*Notas biográficas de Don J. A. Llorente*, Paris, 1818), and *Aforismos Políticos*. The *Discurso sobre una Constitución religiosa* was actually written by an American, but arranged and edited by Llorente. He also superintended an edition of *Oeuvres complètes de Barthélemy de las Casas*, Paris, 1822.

LLOYD, HENRY, a military officer and eminent writer on tactics, born in Wales, in 1729, was the son of a clergyman, who instructed him in the mathematics and classical literature. At the age of seventeen he went abroad, and was present at the battle of Fontenoy. He afterwards travelled in Germany; and having resided some years in Saxony, he was appointed aid-de-camp to marshal Lascy. He was gradually promoted, till, in 1760, he was intrusted with the command of a large detachment of cavalry and infantry, destined to observe the movements of the Prussians. Lloyd executed this service with great success; but soon after resigned his commission in disgust. He was then employed by the king of Prussia; and during two campaigns, he acted as aid-de-camp to prince Ferdinand of Brunswick. After the peace of Hubertsburg, he travelled, and the occurrence of hostilities between Russia and the key, when he offered his services to Catherine II., who made him a major-general. He distinguished himself in 1774, at the siege of Silistra; and subsequently, he had the command of 30,000 men, in the war with Sweden. At length, he left Russia, and travelled in Italy, Spain, and Portugal. He visited general Elliott, at Gibraltar, whence he proceeded to England. Having made a survey of the coast of the country, he drew up a *Memoir on the Invasion and Defence of Great Britain*, which was published in 1798. He retired, at length, to Hage, in the Netherlands, where he died, June 19, 1803.

\* A French ultra, Clausel de Coussergues, having publicly asserted that the inquisition had not burned any person since 1680, Llorente, in his *Lettre à M. Clausel, &c., sur l'Inquisition d'Espagne* (Paris, 1817), proved, that from the year 1760 to 1808 alone, no less than 1578 persons had perished at the stake by its means! And how long is it since this holy tribunal suffered the body of general Miranda, who had died in their dungeons, to be devoured by dogs, and burned a German officer in effigy, because he had, during the war under Napoleon, translated a book, which, in Spain was considered heretical?

the memoir, he was the author of an Introduction to the History of the War in Germany, between the King of Prussia and the Empress-Queen (London, 1791, 2 vols., 4to); and a Treatise on the Composition of different Armies, ancient and modern. These works have been translated into French and German, and Jomini made use of the Introduction for his *Traité des Grandes Opérations Militaires*. Other works of Lloyd's are said to have been bought up and suppressed by the British government, and many of his papers are said to have been taken possession of, at his death, by a person supposed to be an emissary of the British ministry, among which were the Continuation of the History of the Seven Years' War, and a History of the Wars in Flanders. The truth, however, of these statements seems doubtful.

LLOYD'S COFFEE-HOUSE, London, on the northern side of the royal exchange, has long been celebrated as the resort of eminent merchants, underwriters, insurance brokers, &c. As Lloyd's is one of the most extensive and best known insurance offices, the estimate of a vessel at Lloyd's tends much to determine her character among merchants. The books kept here contain an account of the arrival and sailing of vessels, and are remarkable for their early intelligence of maritime affairs.

LLOYD'S LIST, a publication in which the shipping news received at Lloyd's coffee-house is published. On account of the extensive information which it contains, it is of great importance to merchants.

LOADSTONE. See Magnet.

LOAN, PUBLIC, is the name given to money borrowed by the state. There may occur cases which require expenses for which the ordinary revenue of the state is not sufficient. If, in such cases, it is not possible to increase the usual revenue by augmenting the taxes, without great inconvenience to the nation, the state will find it advisable to borrow, and to pay interest till it can discharge the principal. If such loans are appropriated to objects by which the means of production are augmented, the state strengthened, and industry increased, they answer the same purpose as those which an industrious tradesman makes in order to enlarge and improve his business. If he is successful, he will increase his property, and the loan itself will afford the means for repaying it. This will be the case also with the state, when it employs the borrowed capital to open to the nation increased means of profitable industry, by facilitating its intercourse with other countries, giving security to its commerce, and increasing its means of production. But if the loans are expended in useless or unfortunate wars, or in other unprofitable ways, they diminish the means of labour or enjoyment, and burden the nation with taxes to pay the interest and discharge the capital. The capitalists who aid in producing, when they lend their capital to men of business, and receive their interest from the proceeds of their capitals, become unproductive subjects as soon as they lend it to the state which expends it uselessly, for now they live on the products of the capitals of others, when before they lived on the products of their own. As loans, however, may become necessary to the state, the only question is, What is the most advantageous method of making them? A chief distinction among loans is this—that the government promises either the repayment of the capital at a particular time, until which it pays interest, or reserves the liberty to retain the capital, according to its own pleasure, only paying interest regularly. The first kind is liable to occasion trouble to the state, because the payment may often fall at an inconvenient time. The payment of large sums, too, at a particular period, has this disadvantage, that the nation, when the payment is to be made, becomes destitute

of ready money. Therefore large loans are usually contracted in such a way that the payment is made, successively, at many periods, or remains entirely indefinite. The last kind of loans requires that the credit of the state should be undoubted, and also that large capitals should have been accumulated in the hands of many rich people, who find their greatest advantage in disposing of them in loans. Where there is a well founded system of credit, statesmen think it most advantageous to secure only the regular payment of the stipulated interest, but to leave the payment of the capital at the pleasure of the state. This is called the *funding system*, as far as fixed funds are assigned for the perpetual payment of the interest. These *perpetual annuities*, as they are called, had their origin in Britain, but have since been imitated in Holland, France, Russia, Austria, and many other states. In order to provide for the redeeming of the capital, a sinking fund (French, *amortissement*) is established, together with the fund appropriated to the payment of the annuities. This is procured by means of a tax large enough to pay the annuity as long as it lasts, and to redeem, annually, a part of the capital debt. This sinking fund is increased every year, if the annuities, annually redeemed are added to it. (See *Sinking Fund*.) According to this method, the state cannot be said, properly, to borrow capital; it sells annuities, and fixes, at the sale, the rate at which they may be redeemed. They are commonly estimated at so much per cent. The government says—I offer you an annuity of three, four, five, &c. per cent., redeemable at my pleasure. How much will you give me for it? According to the market rate of interest, and the degree of credit which the state enjoys, the capitalists offer fifty, sixty, seventy, eighty, ninety, &c., per cent. The sinking fund aims to discharge the debt, gradually, by redeeming, annually, part of the annuities, at the market price. If the latter exceeds the price for which it had sold its annuities, it will be obliged to redeem them with loss; but if it is less, it can redeem them with gain. Another kind of loan is, when the capitalists pay 100 per cent. at a fixed rate of interest, the government reserving the right to pay the capital at any convenient time. Suppose that the state, when it wishes to borrow, is obliged to pay eight per cent., and that these stocks, in the course of three years, should rise in the market 100 per cent. above par; the state would easily find capitalists, who would lend at the rate of four per cent. annually, and with this it could redeem the eight per cent. stocks. If, therefore, the state has reason to expect that the price of the stocks will rise, its best plan is to receive a fixed capital sum at such a rate of interest as it is obliged to give. But if it fears that the interests or the prices of the stocks will fall, it is for its advantage to procure the necessary money by the sale of stocks at the market price, because it may hope to redeem them at a reduced rate. Sometimes premiums, or the chances of a lottery, are employed to stimulate reluctant capitalists, and sometimes even force. If a government must have recourse to other means than those arising from the annuity or interest offered, it is a certain sign that it enjoys but a feeble credit, or that there is a want of capital. How fertile modern history is in loans of every kind, and into what an unhappy situation many states have fallen, by reason of them, is well known. In Austria, the proprietors of the stocks have been forced, several times, to advance further sums, to avoid losing what they had already lent. See *National Debt*.

LOANDA, or LOANDO, or ST PAUL DE LOANDA; a city of Angola, in a province of the same name, capital of the Portuguese possessions in this part of Africa; longitude 13° 22' E.; latitude

8° 55' S.: population, stated by Clarke at 5,000; by Hassel at 18,000. It is pleasantly situated on the declivity of a hill, near the sea-coast, and the streets are wide and regular. It covers a large extent of ground, but is neither walled nor fortified. It is the seat of a bishop, and contains three convents. The port is safe and spacious; the country around pleasant and fertile, abounding in cattle, corn, and fruits; provisions plentiful and cheap; but the water bad, and must be brought from a neighbouring river, on an island opposite. The houses belonging to the Portuguese are built of stone; the houses of the natives are more numerous, but mean. The Jesuits officiate as priests, and preside over the schools.

LOANGO; a country of Western Africa, of limits somewhat vague. The country subject to the king of Loango extends from the Zaire or Congo, on the south, to cape St Catharine, a coast of upwards of 400 miles; but Loango proper occupies only the middle part, excluding Mayomba on one side, and Malemba on the other. The climate is described as fine; rain of rare occurrence, and never violent, but dews abundant; the soil a red, stiff clay, and very fertile, but little cultivated; the grains are manioc, maize, and a species of pulse, called *maangen*; the sugar-cane grows to a great size; palm-trees are abundant; also potatoes and yams, and the finest fruits grow wild. Among the animals are tiger-cats, ounces, hyænas, hares, and antelopes. The country is thinly inhabited; the population is estimated by De Grandpré at 600,000. The inhabitants are very indolent, and live in the most simple manner. Their houses are formed of straw and junk, roofed with palm leaves. The government is despotic, and the dignity is transmitted only in the female line. Almost the only object for which Europeans resort to this coast is the trade in slaves. While Loango was in the height of its power, its port was almost the exclusive theatre of this trade. The trade has of late much diminished. See Tuckey's *Expedition to the Congo*.

LOANGO; a city, and the capital of Loango, on a river which forms a bay at its mouth, about six miles from the Atlantic; longitude, according to captain Tuckey, 12° 30' E.; latitude 4° 40' N. It is about four miles in circuit, containing only about 600 enclosures, in each of which there is a number of cottages; and the inhabitants are computed at 15,000. The land in the vicinity is very fertile, and the water excellent. The entrance of the bay is attended with some danger. The town is called *Lovango*, *Loangiri*, *Banga*, and *Buali*; by the natives, *Borai*, or *Boori*.
